A SYSTEM OF MEDICINE.
A SYSTEM OF MEDICINE.

EDITED BY

J. RUSSELL REYNOLDS, M.D. F.R.C.P. LOND.

FELLOW OF THE IMPERIAL LEOPOLD-CAROLINA ACADEMY OF GERMANY,
FELLOW OF UNIVERSITY COLLEGE, LOND.
PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE IN UNIVERSITY COLLEGE,
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL
AND TO THE
NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

VOLUME THE SECOND.

CONTAINING

LOCAL DISEASES.

London:
MACMILLAN AND CO.
1868.
LONDON:
R. CLAY, SON, AND TAYLOR, PRINTERS,
BREAD STREET HILL.
LOCAL DISEASES.

§ I.—Diseases of the Nervous System.
   A. General Nervous Diseases.
   B. Partial Nervous Diseases.
      1. Diseases of the Head.
      2. Diseases of the Spinal Column.
      3. Diseases of the Nerves.

§ II.—Diseases of the Digestive System.
   A. Diseases of the Stomach.
CONTRIBUTORS TO THE SECOND VOLUME.

Francis Edmund Anstie, M.D., F.R.C.P. Lond.; Senior Assistant Physician to the Westminster Hospital; Lecturer on Materia Medica in the Westminster Hospital Medical School.

Henry Charlton Bastian, M.A., M.D. Lond., F.L.S.; Professor of Pathological Anatomy in University College; Assistant-Physician to University College Hospital.

Thomas King Chambers, M.D. Oxon, F.R.C.P. Lond.; Hon. Physician to H.R.H. the Prince of Wales; Consulting Physician and Lecturer on Medicine in St. Mary’s Hospital.

Wilson Fox, M.D., F.R.C.P. Lond.; Holme Professor of Clinical Medicine in University College; Physician to University College Hospital.

Samuel Jones Gee, M.D., M.R.C.P. Lond., University Medical Scholar, Assistant-Physician to the Hospital for Sick Children.

William Withey Gull, M.D., F.R.C.P. Lond.; late Physician to Guy’s Hospital.

J. Hughlings Jackson, M.D. St. Andrew’s; Physician to the National Hospital for the Paralysed and Epileptic; Assistant-Physician to the London Hospital.

William Campbell Maclean, M.D. Edinburgh; Deputy Inspector-General of Hospitals; Professor of Clinical and Military Medicine in the Army Medical School, Netley.

Henry Maudsley, M.D. Lond.; Physician to the West of London Hospital; Lecturer on Insanity at St. Mary’s Hospital Medical School.

Charles Bland Radcliffe, M.D., F.R.C.P. Lond.; Physician to the Westminster Hospital, and to the National Hospital for the Paralysed and Epileptic.

John Netten Radcliffe, Honorary Secretary of the Epidemiological Society; Medical Superintendent of the National Hospital for the Paralysed and Epileptic.

J. Spence Ramskill, M.D. Lond.; Physician to the London Hospital, and to the National Hospital for the Paralysed and Epileptic.

William Roberts, M.D., F.R.C.P. Lond.; Physician to the Manchester Royal Infirmary; Lecturer on Medicine in the Manchester School of Medicine.

William Rutherford Sanders, M.D., F.R.C.P. Edinburgh; Physician to the Royal Infirmary, and Lecturer on the Institutes of Medicine, Edinburgh.

Henry G. Sutton, M.D. Lond.; Assistant-Physician to the City of London Hospital for Diseases of the Chest.
CONTENTS.

INTRODUCTION, by The Editor ........................................ 3

LIST OF GENERAL NERVOUS DISEASES ............................ 7

INSANITY, by Henry Maudsley, M.D. ............................... 8
  Synonyms ..................................................................... 8
  Definition ..................................................................... 8
  Classification ............................................................. 10
  Causes ......................................................................... 11
    Forms of Insanity and their Symptomatology ................. 17
      Melancholia .......................................................... 18

PART II.

In the Second Part of this System of Medicine are described those diseases in which particular organs, or systems of organs, are either primarily or especially deranged. We have, therefore, to deal with:—

Partial Diseases; or, Affections of Particular Organs; and shall include in the present volume

§ I.—DISEASES OF THE NERVOUS SYSTEM.
A. General Nervous Diseases, and those of Uncertain Seat.
B. Partial Diseases of the Nervous System.
   1. Diseases of the Head.
   2. Diseases of the Spinal Column.
   3. Diseases of the Nerves.

§ II.—DISEASES OF THE DIGESTIVE SYSTEM.
A. Diseases of the Stomach.
I.—DISEASES OF THE NERVOUS SYSTEM.

INTRODUCTION.

BY THE EDITOR.

A few words are necessary to explain the principle of classification adopted with regard to the diseases which find their place in this, the first, section of "partial diseases," or "affections of particular organs."

All the maladies which are treated of in these volumes have been already divided into two large groups, "general" and "local" (see Classification of Diseases, vol. i. p. 24); and the basis of such division has been described. Some diseases appear so to affect the whole body at once, that all its functions are impaired or altered; and not only so, but they are implicated to such an equality of degree that it is always difficult, and sometimes impossible, to say upon which system of organs, if upon any, the greater weight of the burden falls. Of such diseases the first volume of this System of Medicine contained the history. In the present, the second volume, we have to deal with another class of affections: viz. with those in which we have little or no difficulty in localising the disease; maladies with regard to which we say at once that they are diseases of the nervous system, or of the respiratory system, or of the system pertaining to the circulation. It is not intended that such diseases are accurately limited to the particular systems from which they derive their names; for we know well that both heart and lungs are, or may be, disturbed in epilepsy, in apoplexy, and in paraplegia; and, on the other hand, that no severe inflammation can occur in either lungs or heart without the simultaneous development of some corresponding disturbance in the nervous centres. Furthermore, we know that there is sometimes great difficulty in determining whether we have to deal with a general disease, or with some lesion of a particular organ; or, even allowing that some particular organ is especially affected, it is sometimes a matter of grave doubt as to which system of organs that particular one belongs. Tubercular meningitis has been mistaken for typhoid fever, and vice versa.
versâ; abscess of the brain has been confounded with malarial poisoning; and, again, tumours in the brain have been regarded as diseases of the stomach; while all the symptoms of cancer of the stomach have been explained away by the fiction of "spinal irritation." Knowing, however, the inherent difficulties of the case—viz. those which arise out of the fact that all the systems of organs have marvellously close relations with each other—and being aware, moreover, of those accidental hindrances which arise out of either our own ignorance or our want of tact in the application of such knowledge as we have attained; we still hold it to be desirable that, in this System of Medicine, we should maintain the distinction between general and local diseases, and that we should take as our basis for classification of the latter, the particular systems of organs. We believe this to be so, because the lines which are drawn in making these distinctions define groups of diseases, the individual members of each of which have inter se closer clinical relations than have those which belong to different, although contiguous groups; and because in the vast majority of cases it is comparatively easy, and sufficient for all the practical purposes of "classification," to say that a particular disease under consideration is "general" in its character, or is "partial," in the latter instance especially affecting this or that great system of organs, such as the nervous, the respiratory, or the digestive.

The principle of division thus established with regard to all diseases—viz. that of limitation, or localisation—is again applicable, as a means to be employed for the primary subdivision of the large group of diseases forming the first section to be considered in this volume; and accordingly "diseases of the nervous system" are distributed under two headings—the "general," and the "special" or "partial."

Under the former, the "general," are described those affections which exhibit their phenomena in all parts of the nervous system—those in which brain, spinal cord, and nerves seem to be all, more or less intensely, and more or less widely, involved; while under the latter, the "partial," are detailed those in which the brunt of the malady is borne by particular parts of the nervous system—the brain, the cord, the nerves, or their appendages.

It will be seen at once, by a reference to page 7, that under the former, the "general," are enumerated, together with those which strictly merit that designation, some diseases which appear to affect certain portions of the nervous system either more profoundly or more essentially than they influence others; and further, that some morbid conditions are described which, although limited in the distribution of their symptoms, have no such definite pathological anatomy that we can affirm, with anything like satisfaction, what part of the nervous system is in them primarily at fault. The first large group, therefore, is made to include, together with those in which the whole nervous apparatus is equally disturbed, some diseases apparently partial in their distribution, and others which, in the present state of science, are of "undetermined seat." Among the members of this first large
INTRODUCTION.

group, for example, there are placed epilepsy, hysteria, and such
diseases as show themselves in altered functions of the brain, cord,
and nerves—occasionally one great division of the nervous system,
and sometimes another, presenting the most marked derangement,
but all divisions being more or less involved in morbid change of
either function or structure, or both:—and in the same large group
we find wasting palsy, chorea, writers' cramp, and allied affections,
which, although they exhibit the maximum of their obvious symptoms
in particular parts of the nervous system, are yet of such uncertain
pathology, that it would be injudicious at present to describe them as
diseases of either brain, cord, or nerves, exclusively.

So far as the pathology of these will allow, they will, when ex-
amined in detail, be referred to their proper places; but it is thought,
for the simple purpose of arrangement, desirable to keep within the
limits of ascertained facts and principles, by retaining them in the
position already described. The other alternative, that of placing them
under particular headings, while it might confer a greater amount of
apparent scientific precision, would, I believe, be attended by less real
scientific accuracy; inasmuch as it would give an undue prominence to
many hypotheses, very valuable in themselves, as forming the
framework of both thought and investigation, but which, being as
yet no more than hypotheses, are not entitled to hold high rank among
the conditions upon which classification should be based. The
diseases known, for example, as cerebritis, myelitis, and neuritis,
respectively, have clinical histories and well-known pathological con-
ditions related to one another in a manner much more definitely
ascertained than have such affections as ataxy, paralysis agitans, and
wasting palsy. We have referred the symptoms of the first series to
their anatomical changes, whereas it cannot be said that we have done
so with regard to the second group. Much more is known about
the latter than was known a few years ago; but observations, during
life and after death, have to be multiplied and verified before we can
ascribe those diseases, with scientific precision, to particular localities
and kinds of structural lesion.

Again, the kind of distinction between hæmorrhage into the corpus
striatum and hæmorrhage into the spinal cord, is, in its clinical re-
lations, widely different from that which can be established between
either of those two affections and ataxy, or chorea. In the one we
are dealing with what is definitely known; in the other, with what is
as yet indefinite, and only approaching scientific arrangement. Upon
these grounds, therefore, the primary division is made into diseases of
“general” distribution, or of undetermined locality, and “partial”
diseases, or those having a recognised pathological anatomy.

In the second group of diseases of the nervous system—viz., those
described as “partial”—the principle of arrangement is sufficiently
obvious to need but little elucidation. In the first place, a subdivision
is made upon simply anatomical grounds—viz. into affections of the
cranium, the spinal column, and the nerves; and each of these is
again subdivided upon an anatomical basis—diseases of the cranium being distributed under the categories of “meninges” and “nervous tissues,” such as brain, cerebellum, and the like; while diseases of the spinal column are distributed in a similar manner. The next principle of division is that determined by the nature of the anatomical changes which these tissues, respectively, undergo. Here an attempt has been made to place in close proximity those affections which have the most highly-marked clinical similitude—an attempt, however, which is only carried to such a point as shall not interfere with the more general arrangement.

It is not necessary to enter further into the detail of this classification, as the principles upon which it is based are sufficiently obvious for all the practical purposes of this System of Medicine.
§ I.—DISEASES OF THE NERVOUS SYSTEM.

These diseases are divided into two large groups, viz. A, those of general distribution, or of uncertain seat; and B, those which are partial, and which occupy known relations to particular portions of the nervous system.

A. GENERAL NERVOUS DISEASES, AND THOSE OF UNCERTAIN SEAT:—

INSANITY.

BY HENRY MAUDSLEY, M.D.

SYNONYMS.—Insanity; Madness; Mental or Cerebro-Mental Disease; Mental Derangement; Mental Alienation; Mental Aberration; Unsoundness of Mind; Lunacy.

DEFINITION.—So many and various in kind and degree are the forms of mental derangement included under Insanity, that it is not possible to give a definition of it that shall be at the same time comprehensive and exact. If the definition is wide enough to comprise all varieties, it is in danger of including eccentricities that fall short of disease; if exact enough to be definite, then it must exclude many slight cases of undoubted mental disease. As various as are the features or the voices of men, so various are their mental characters; and as no two persons are exactly alike in mental character and development, so in no two instances of the degeneration of mind do the morbid features exactly correspond. The development of other organs of the body, taking place before birth after a common type, is very much alike in different persons, and the diseases of them have a great resemblance; but the real development of the brain as the organ of conscious life, taking place after birth in relation to surrounding circumstances, and thus gradually issuing in the formation of individual character, is different in different persons, and accordingly cerebro-mental diseases present manifold varieties of features. As regards any particular case of Insanity, it is necessary then to fix attention on two points: first, on the change of individual character—the alteration from the former self; secondly, on the want of harmony, or the discord, between the individual and his surroundings. For although the morbid phenomena of the diseased mind witness in some measure to the degree of its previous development, yet the degeneration which disease implies must needs display itself in an alteration in the kind of manifestation of feeling, thinking and acting—in other words, in a changed self; while again the import, as morbid, of the phenomena displayed can only be rightly weighed in relation to the individual sphere of life. It is, for example, quite possible, though apt to be forgotten in practice, that sentiments and acts which are habitual in the lowest strata of life may be sure signs of mental disease when uttered and done by one in a high social sphere.
Bearing in mind the difficulties inherent in the nature of the subject, and which have led to every sort of definition by every writer who has not forborne the task in despair, we may declare Insanity to consist essentially in a morbid derangement, generally chronic, of the supreme cerebral centres—the grey matter of the convolutions or the intellectorum commune—giving rise to perverted feeling, defective or erroneous ideation, and discordant conduct, conjointly or separately, and more or less incapacitating the individual for his due social relations.*

This definition has the merit of fixing attention, first, on the reception of impressions from the external world—the mode of feeling, or the affective life; secondly, on the mental fashioning or elaboration of impressions—the modes of ideation or intellection, the intellectual life; and, thirdly, on the reaction of the individual on the external world—the mode of action or conduct: it answers also to the best psychological division of mind into feeling, cognition, and will. How desirable it is not entirely to overlook the social relations, will be plain when we reflect that it is in the irregularities of the individual, as an element in the social system, that the morbid character of Insanity fundamentally consists. Certainly the definition is far from being perfect, as in the nature of things it must be, so long as it is impossible to draw the line where sanity ends and Insanity begins, or even to say positively whether a particular person is insane or not; but against its manifest defects may be put its positive merits—namely, that it fixes the grey matter of the convolutions, the undoubted nervous centres of intelligence, as the principal seat of morbid action in Insanity; that it distinctly declares that Insanity may be exhibited either in moral perversion only, or in the actions of the patient, or in delusion; and, lastly, that it sets forth how Insanity destroys the relations and responsibilities of the individual in the social system, making him very much like what a morbid element is in the organic system—something which cannot take its due place in the general harmony, and which must either be eliminated from it or sequestered and rendered harmless in it. A man may certainly have disordered feeling, may think and judge erroneously, and act extravagantly, without being insane; but if he does so as a regular thing, and without any adequate cause in external circumstances—if he does so in fact by reason of a steadily acting internal cause, a derangement of his supreme cerebral centres—then he is insane. The standard by which to measure the perversion is, first, that of the kind—that which is fixed by the general consent of mankind; and, secondly, that of the individual—that which is justified by the degree of his previous mental development.

Many and varied as are the forms which madness takes, there are still beneath superficial differences certain characters of essential agreement; and accordingly genuine groups or types may be described,

---

* Ideation, now so commonly used, was first suggested and employed by Mr. James Mill in his Analysis of the Human Mind. Dr. Darwin aptly designates the common centres of intelligence as the Intellectorum Commune in his Zoology.
notwithstanding the fact that cases marking every grade of transition between one group and another are undoubtedly met with in practice. Of Insanity may still be said what Burton long ago said of melancholy:—"I could give instances of some that have had all three kinds semel et simul, and some successively . . . What physicians say of distinct diseases in their books, it much matters not, since that in their patients' bodies they are commonly mixed."

**Classification.**— The classification commonly adopted in this country, and yet indispensable for practical purposes, is a modification of that proposed by Esquirol, and is as follows:—

I. Mania . . . \{ Acute, or Raving Madness.  
II. Monomania.  
III. Melancholia.  
IV. Moral Insanity.  
V. Dementia . \{ Primary.  
VI. Idiocy, including Imbecility.  
VII. General Paralysis or Paresis.

In Germany, the classification which finds most favour stands thus:—

I. Die Depressionzustände.  
1. Die Hypochondrie.  
2. Die Melancholie.  
II. Die Exaltationzustände.  
1. Die Tobsucht.  
2. Der Wahnsinn.  
III. Die psychischen Schwächezustände.  
1. Die Verrücktheit.  
2. Der Blödsinn.  
3. Idiotismus und Cretinismus.  
IV. Der paralytische Blödsinn, Die allgemeine Paralysie der Irren.  
IV. Paralytic dementia, General Paralysis of the Insane.

Forasmuch as almost every writer on Insanity has his own classification, and as no less than forty different classifications might be enumerated, and the list still not be exhausted, it would plainly be unprofitable to discuss here a subject which has been compared, not without reason, to the confusion of tongues at the tower of Babel.†

† Die Gruppirung der psychischen Krankheiten und die Entcheidung der Seelenstörungen. Von Dr. K. Kahlbann. 1863. The author enumerates upwards of forty proposed classifications, and ends by proposing a new one of his own.
INSANITY.

11

Adopting for the purposes of description the classification in common use, artificial as it is, it will be most convenient to indicate any modification that may seem desirable after that the origin, the varieties, and course of progress of mental disease have been set forth in the account of its causation and symptomatology.

Causes.—These are usually divided into physical and moral, though without any exactness in such discrimination being really practicable. Two persons are exposed to like severe mental shocks: one of them becomes insane, the other does not. Has the madness, then, been produced by a moral cause? In the former case, there was probably some innate vice of nervous element—some predisposition of it to disease, or some accidental nervous depression, by reason of physical disease, or other cause, whereby Insanity has been produced by a moral cause that has had no such ill effect in the latter case. The entire causes have not, then, been in reality the same. What should ever be borne in mind is, that all the conditions which conspire to the production of an effect are alike causes, alike agents, and that there is, in most cases of Insanity, a concurrence of conditions, not one single effective cause. Mental alienation often appears as the natural issue of all preceding conditions of life, mental and bodily—the outcome of the individual character as affected by certain circumstances; in such case, the germs of disease may have been latent in the foundations of the character, and the final outbreak is but the explosion of a long train of antecedent preparations. In vain, then, is it to try to fix accurately upon a single cause, moral or physical; a common mistake, on the part of those who think to do so, being to fix upon that which is in reality an early symptom as the supposed cause. On this rock have hitherto foundered all etiological classifications of Insanity. It will be most convenient to deal with the causes as predisposing or remote, and as exciting or proximate.

a. Predisposing Causes.—There are general causes, such as the climate of a country, the form of its government and its religion, the state of its civilisation, the occupation and habits of its inhabitants, which work together in the course of generations to the formation of a national type of character, wherein there may be greater or less proneness to Insanity. Reliable data respecting the frequency of Insanity in different countries are, unfortunately, still wanting, and even the question whether it has increased with modern civilisation has not been positively settled. Travellers certainly agree that it is a rare disease amongst barbarous people; whilst in the different civilised nations of the world there is, so far as can be ascertained, an average of one insane person in 500 inhabitants. The undoubted steady increase, again, of the insane under care and observation, would seem to be greater than can be fairly accounted for by the greater attention now given to their welfare; while theoretical considerations indicate that the feverish activity of life, the numerous passions and the great strain of mental work incident to the multiplied industries
and eager competition of an active civilisation, cannot fail to augment
the liability to mental disease. Though not yet exactly provable by
statistics, there is still great reason to believe that, with the progress
of mental development through the ages, there is a correlative dege-
neration going on, and that Insanity is a penalty which our present
civilisation necessarily pays.*

Sex.—Though Esquirol and Haslam thought Insanity to be a little
more frequent among women than among men, it is now generally
agreed that the converse is true. Dr. Thurnam affirms men to be
more liable to mental disorders than women; and Dr. Jarvis came to
the same conclusion from an examination of the statistics of different
countries. Recently, however, it has been stated that the female sex
is more liable to suffer from hereditary Insanity.† On whichever
side, male or female, the uncertain difference lies, it is probably
inconsiderable.

Period of Life.—Insanity is rare before puberty, though every form
of it, except general paralysis, may occur even so early in life; it is
far more frequent between the ages of 16 and 25; but it is most fre-
cquent of all during the period of full mental and bodily development
—from 25 to 45—when there is the widest exposure to its causes.
The internal revolution which takes place in women at the climacteric
period leads to many outbreaks of Insanity in them between 40 and
50. In men there appears to be a climacteric period between 50
and 60, when Insanity sometimes supervenes: an old man may be
found to be keeping a mistress in secret, or to be making foolish
proposals of marriage, when, forerunning complete dementia, sensual
impulses, clothed in the morbid habit of delusion, mock the extinction
of sexual function.

Condition of Life.—The statistics hitherto collected in regard to
this point are of little or no value. Whether a particular profession
or trade favours the production of Insanity is generally a question of
the habits incidental to its pursuit—whether those who follow it live
soberly and temperately, or whether they are addicted to intemperance
and riotous living. On the whole, however, those who work with the
head are more liable to mental disease than those who work with the
hand, and they are less likely to recover when once attacked.

Other things being equal, it is certain that Insanity is propor-
tionately more frequent amongst the unmarried than the married.

* The reports of the Lunacy Commissioners show that, on the 1st January, 1849,
there were 14,560 patients in the hospitals, asylums, and licensed houses of England and
Wales; that on the 1st January, 1855, there were 20,493; and that, on the 1st January,
1865, there were 29,425. These numbers do not include the insane residents in work-
houses and private houses, the number of whom is at least 15,000. This large increase
must not be attributed to the increase of insanity in the population; as the Commis-
sioners point out in their report for 1860, it is mainly owing (1) to the large number of
cases, formerly unreported, which have now been brought under observation; (2) to the
increased number of those scot to asylums, especially of paupers; and (3) to the pro-
longation of life in those who have been brought under proper care.

† Statistics of Insanity of the Crichton Royal Institution, by H. G. Stewart, M.D.;
Ment. Science, 1864.
Individual predisposition.—The heritage which a man has from his parents may alone, or together with the circumstances of early education, give rise to an individual predisposition to mental derangement. Unquestionably some persons have what may be called the insane temperament—a certain neurosis or diathesis, easily prone to degenerate into actual disease; they feel impressions in a way which other people do not feel them, are disposed to sudden impulses of strange feelings and desires, to whimsical caprices of thought and eccentricities of action, and they not unfrequently carry in their countenance and bearing the marks of their evil heritage. They have what Willis long ago called the diathesis spasmodica, an irritable weakness of nervous constitution, in which, if there be not positive disease, there is the well-prepared ground of disease. Authors are not agreed as to the proportion of cases of Insanity in which positive hereditary taint is detectable: some, like Moreau,* putting it as high as nine-tenths; others, as low as one-tenth. The most careful researches fix the proportion as not lower than one-fourth, if not so high as one-half; and there can be no doubt that the tendency is to increase the proportion as investigation becomes more searching and exact. It must be borne in mind that hereditary predisposition may be of every degree of intensity, so as, on the one hand, to conspire only with certain more or less powerful exciting causes, or, on the other hand, to suffice of itself to give rise to Insanity even amidst the most favourable external circumstances. Again, not Insanity only in the parents, but any form of nervous disease in them—epilepsy, hysteria, and even neuralgia—may predispose to Insanity in the offspring, as, conversely, Insanity in the parent may predispose to other kinds of nervous disease in the offspring. Procreation during the temporary Insanity of drunkenness, and too much interbreeding in families, are both recognised causes of a predisposition to mental degeneration. Some, like Lagol and Schroeder van der Kolk, have maintained that scrofula of parents may generate a predisposition to Insanity in the children; and whether this be so or not, it can admit of no question that the undoubted transformation which diseases undergo through generations is a subject deserving of further and more exact study.† Baillarger has proved, what Esquirol observed, that Insanity descends more often from the mother than the father, and from the mother to the daughters more often than to the sons. Children born before the outbreak of an attack are less likely to suffer than those born after an outbreak.

An injudicious education may aggravate an inherent mischief; the parent not only transmitting a taint or vice of nature to the child, but fostering its increase by the influence of a bad example, and by a foolish training at that period when the young mind is very suscep-

* La Psychologie Morbide dans ses Rapports avec la Philosophie de l'histoire. Par Dr. J. Moreau.
tible, and the direction given to its development decisive for life. Where there is no innate taint mischief may still be wrought by enforcing an unnatural precocity, wherein is often planted the germ of future disease. Parental harshness and neglect, repressing the child's feelings, stifling its need of love, and driving it to a morbid self-brooding, or to take refuge in a world of vague fancies, is sometimes not less injurious than a foolish indulgence, through which it never learns the necessary lessons of renunciation and self-control.

b. Exciting Causes.—The so-called moral causes are generally, though not universally, held to be more frequent than the physical causes: Pinel thought them to be twice, Esquirol four times, as frequent; while Guislain attributed 66, Parchappe 67, out of 100 cases of Insanity to moral causes.* It is not the way of great intellectual exercise, when unaccompanied by emotion, to lead to mental derangement; it is when the feelings are deeply engaged, when the mind is the theatre of great passions, that it is most moved and its stability most endangered. The depressing passions are most effective in this regard: grief, religious anxiety, disappointed affection or ambition, jealousy, the wounds of an exaggerated self-love, and the painful feeling of being unequal to responsibilities, or other such conditions of mental agitation and suffering, are most apt to reach a violence of action by which the equilibrium is lost. It is especially when the individual has by a long concentration of thought, affection, and desire on a certain aim or object grown into definite relations with regard to it, and made it, as it were, a part of the inner life, that a sudden and entire change, shattering long-cherished hopes, is most likely to produce Insanity; for nothing is so fraught with danger to the stability of the strongest mind as a sudden great change in external circumstances without the inner life having been gradually adapted thereto. Hence, also, it is that a great exaltation of fortune, as well as a great affliction, rarely fails to affect for a time the strongest head and sometimes quite overturns a weak one; though the strong mind succeeds after a time in establishing an equilibrium between itself and its new surroundings, which the feeble mind cannot do. Men do not, however, often become insane from joy; and when one of the expansive passions, as ambition, religious exaltation, overweening vanity in any of its Protean forms, leads to mental derangement, it does not, like a painful passion, act either directly as the sudden cause of an outbreak, or indirectly by producing organic disorder and subsequent Insanity, but it exhibits its effects slowly, as a gradual development or exaggeration of a particular vice of character.

Among the causes of mental disturbance which it would be difficult to pronounce other than moral, but which are really due to physical conditions, are those incident to the great mental revolution produced by the development of the sexual system at puberty; when there occurs, as Goethe aptly expresses it, "an awakening of sensual impulses.

* Pinel, On Insanity, translated by Dr. Davis; Esquirol, Traité des Maladies Mentales; Guislain, Traité sur l'Aliénation Mentale; Parchappe, Traité de la Folie.
which clothe themselves in mental forms, of mental necessities which clothe themselves in sensual images." The great moral commotion produced at this period, is the cause of an unstable equilibrium of mind, which is just as dangerous as if it were produced by some external cause; and which, if hereditary predisposition exists, may, without further auxiliary cause, issue in Insanity.

Of the physical causes of Insanity, intemperance occupies the first place; acting not only as a direct cause, but indirectly through the emotional agitations incident to an irregular life of dissipation and excess. Opium, Indian hemp, and other narcotics notably give rise to temporary disorder of mind, and, if abused by long indulgence, they may undoubtedly lead to permanent degeneration. Self-abuse is the cause of a particularly disagreeable form of Insanity, characterised by intense self-feeling and conceit, and profound moral disturbance in the earlier stage, and later, by failure of intelligence, nocturnal hallucinations, and suicidal or homicidal propensities. Epilepsy is sometimes followed by a most violent and dangerous mania, and, when of long standing, produces loss of memory, and general failure of intelligence. Sometimes an outbreak of mania precedes or takes the place of an epileptic attack; and it may happen that a painful form of moral derangement, with periodical exacerbations—a masked epilepsy—precedes for months the appearance of the genuine epileptic convulsions.

Chronic diseases, constitutional and local, favour the production of Insanity in many instances. Anaemia plays the same weighty part as in the causation of other nervous diseases. It is not without influence in many cases of hysterical insanity, as well as in the asthenic form which occurs during lactation; and when suddenly produced by great loss of blood, it may be the cause of an attack of puerperal mania. The syphilitic virus is now known to affect nervous element injuriously, and of late an extreme form of dementia has been ascribed to a syphilitic exudation, circumscribed or diffused, on the surface or within the substance of the brain. Tuberculosis is frequently associated with mental disease, one-fourth of the deaths in asylums being due to phthisis; and a form of suspicious melancholia, having something of the character of dementia about it, has been described as phthisical insanity.* The disappearance of a skin disease, or the suppression of an accustomed discharge, has of old been known to be at times followed by an attack of mania or melancholia; and Dr. Garrod has seen numerous cases of mania which have been caused by retrocedent gout. Of local diseases favouring the production of Insanity, the influence of those of the heart seems to have been overrated; out of 602 post-mortem examinations made in the Vienna asylum, the heart was found to be affected in one-eighth, and in some of these only very slightly. Abdominal diseases are sometimes genuine causes of melancholia; and diseases of the sexual organs in women have always had

a high place assigned to them in the scale of causes. It is certain that an attack of mania has followed the suppression of the menses, and that the return of menstruation is often followed by recovery from Insanity; but it is certain also that outbreaks of maniacal fury, or of suicidal or of homicidal violence, have coincided with the period of menstruation. Schroeder van der Kolk had a patient profoundly melancholic, who suffered also from prolapsus uteri, and in whom the melancholia disappeared directly the uterus was restored to its place. Flemming relates two similar cases in which the melancholia was cured by the use of a pessary, in one of them regularly returning whenever the pessary was removed; and I have seen, in one case, severe melancholia of two years' duration disappear after the cure of a prolapsus uteri. Instances are on record in which a woman has regularly become insane during each pregnancy; and, on the other hand, Guislain and Griesinger mention a case, respectively, in which Insanity disappeared during pregnancy, the patient at that time only being rational. Puerperal Insanity occurs at or after childbirth: during the agony of delivery there may be a brief attack of maniacal fury, in which the child is killed by the mother; or insanity comes on a few days after delivery, apparently from blood-poisoning; or, lastly, it occurs from a few weeks to a few months after delivery, and is then seemingly due to the exhaustion produced by lactation, in conjunction with depressing moral influences.

After acute febrile diseases, as typhus and typhoid fever, the acute exanthemata, acute rheumatism, and pneumonia, Insanity sometimes follows. In such cases it either takes the form of acute dementia, or of the mild delirium of nervous exhaustion, from which recovery takes place in a few days; or it steadily passes into a chronic and persistent form, especially if there be hereditary taint; or it is acute, recovery taking place for a time, but, as happens after injuries to the head, being followed by subsequent marked change of temper, and finally chronic Insanity.*

Injuries of the head, when not followed by any immediate ill consequences, may still, after a time, lead to incurable Insanity, through the degenerative changes which they induce in the cortical layers. Insolation notably acts perniciously on the cerebral centres, either by causing acute hyperaemia and edema, or, as is more probable, by over-stimulation and consequent exhaustion of nervous element. Abscesses and tumours of the brain, cysticerci,† effusions of blood, do not directly produce mental disorder, which is indeed often absent; and when they do give rise to such disorder, they seem to act indirectly

† On Cysticerci, Archiv. der Heilkunde, 1862, Prof. Griesinger. A case of insanity in which several cysticerci were found in the brain is related by Joire in the Gazette des Hôpitaux, 1860; another by Dr. Snell in the Zeitschrift für Psychiatrie, 1861; another by Baillarger in the Arch. Clin. des Maladies Mentales, 1860; and another by Dr. Saunders in the Report of the Devon County Asylum for 1864.
by a reflex or sympathetic action. Professor Gerhardt* relates one case in which mental derangement was the first symptom of an embolism, the paralytic phenomena following later; and in a case recorded by L. Meyer, chronic tubercular meningitis gave rise to mental disorder. Instances are on record in which Insanity, like tetanus, has been caused by peripheric injury of nerve; and of great interest are those cases, long since observed by Dr. Darwin, in which it occurs as the transference of disorder from the spinal centres.

Let it be distinctly understood, however, that of the above enumerated causes of Insanity, it scarcely ever happens that one acts singly; many of them would have no such ill effect, except through the co-operation of hereditary predisposition, and the latent hereditary taint might remain happily dormant, but for the concurrence of unfavourable conditions, physical or moral. Whenever such inborn taint does exist, it is certain that any great revolution in the system, whether arising out of external circumstances, or from internal causes, such as puberty, pregnancy, and the climacteric period, will be fraught with danger to the mental equilibrium.

Forms of Insanity and their Symptomatology.—A glance at the symptoms of the various forms of mental disease reveals at once the existence of two well-marked groups: one of these including all those cases in which the mode of feeling or the affective life is chiefly or solely perverted—in which the whole habit or manner of feeling, the mode of affection of the individual by events, is entirely changed; the other, those cases in which ideational or intellectual derangement predominates. More closely scanning the symptoms, it is seen that the affective disorder is the fundamental fact; that in the great majority of cases it precedes intellectual disorder; that it co-exists with the latter during its course; and that it frequently persists for a time after this has disappeared. Esquirol rightly, then, declared “moral alienation to be the proper characteristic of mental derangement.” “There are madmen,” he says, “in whom it is difficult to find any trace of hallucination, but there are none in whom the passions and moral affections are not perverted and destroyed. I have in this particular met with no exceptions.” This experience is in entire accord with that of every observer of Insanity, and with the principles of a sound psychology. It is the feelings that reveal the genuine nature of an individual; it is from their depths that the impulses of action come, while the intellect guides and controls; and accordingly in a perversion of the affective life is revealed a fundamental disorder of the innermost nature, a disorder which will be exhibited in acts, rather than, as ideational disorder is, in words. To insist upon the existence of a delusion as a criterion of Insanity, is to ignore some of the gravest and most dangerous forms of mental disease.

Melancholia.—Here the fundamental fact is a deep, painful feeling of profound depression and misery, a great mental suffering. The patient's feeling of external objects and events is perverted, so that he complains of being strangely and unnaturally changed: impressions which should rightly be agreeable, or only indifferent, are felt as painful; friends and relatives are regarded with sorrow or aversion, and their attentions with suspicion; he feels himself entirely isolated, and can take no interest in his affairs; and he either shuns society and seeks solitude, lying in bed and unwilling to exert himself, or he utters his agony in sounds ranging from the moan of dull ache to the shrill cry of anguish, or in ceaseless gestures of misery, or even in some convulsive act of desperate violence. All this while there may be no delusion; the patient may be conscious of the change in himself, may grieve over his unnatural state, and strive to hide or fitfully resist it; but as he gets worse he becomes more and more self-absorbed, more and more indifferent to, or distrustful of, those around him, and, finally, succumbs entirely to his affliction. Then it is, usually, that the vast and formless feeling of profound misery takes form as a concrete idea—in other words, is condensed into some definite delusion: this now being, as it were, the expression of it. The patient believes that he has committed some great crime, for which he must suffer death on the gallows; that he has blasted the happiness of his family; that he is possessed by the devil, or is the victim of a persistent and cruel persecution, by magic or by magnetism; that he has committed the unpardonable sin, and is for ever damned. The delusion is not the cause of the feeling of misery, but is engendered of it, and takes different forms according to the degree of the patient's culture, and the social, political, or religious ideas prevailing at the particular epoch: what the uneducated person attributes to witches or to devils, the man of some cultivation attributes to magnetism or to political conspiracy. In some cases it is striking how disproportionate the delusion is to the extreme mental anguish—how inadequate it is as the expression of it: one, whose agony is that of the damned, will aver that it is because he has drunk a glass of beer which he should not have done, or because he has muttered a curse when he ought to have uttered a prayer. With him who believes that he is doomed to infinite and eternal misery, it is not the delusion, but the affective disorder, that is the fundamental fact; there can be no adequate or definite idea of the infinite or eternal, and the insane delusion of eternal damnation is but the vague and futile attempt at expressing an unutterable real suffering. It is noteworthy, again, how much the affliction of the melancholic subsides sometimes when a definite delusion is established: the vast feeling of vague misery which possessed the whole mind has undergone systematization in definite morbid action; and when the delusion is not active, but reposes in the background, not otherwise than as ideas constantly lie dormant in the sound mind, the patient may be tolerably cheerful.

As many as are the varieties of mental pain or suffering, so many
INSANITY.

varieties are there of melancholia; the essential character of all of them being an oppression of the self, the weight of a great suffering, out of the feeling of which springs the delusion of being overpowered by some external agency, demonic or human, or of salvation lost through individual sins. The classification of melancholia according to the accidental character of the delusion is, therefore, of little value. Two well-marked groups may be distinguished: the first, including those who have a definite delusion—Lypemania; the second, those who have no definite cause of terror, but display a fearful apprehension of everything possible and actual—Pantophobia. It is desirable also for certain purposes to distinguish a hypochondriacal form of melancholy.

Hypochondriacal melancholia represents one of the mildest forms of melancholic depression; the anxiety proceeding from an extravagant feeling of bodily disease and exaggerated notions of danger. The morbid feeling, which is not usually without some physical cause in the organism, may be general, or it may be confined to single anomalous sensations. The patient is anxious and depressed; he complains of anomalous feelings, which he watches and analyses very attentively; his heart flutters fearfully, a film passes over his eyes, and there are strange sensations in his head; he examines his pulse, tongue, and evacuations, and rarely fails to find something abnormal in all of them. He is commonly irresolute, sluggish, and indifferent to what is not related to the circle of his morbid ideas; but in some cases paroxysms of anguish and despair rise to such a height as to sweep away all power of self-control, and to issue in homicidal violence. The intelligence, though generally sound in regard to all matters that are not overclouded by the morbid feelings, is still profoundly affected through these. Hence, though hypochondriacal melancholies do not often commit suicide or homicide, they may do both: a man in the Somerset Asylum, for example, cut into his belly with a piece of glass, and dragged out his small intestines, in order to let the wind out. The transition is indeed gradual from the less severe forms to those in which the anomalous sensations are not merely exaggerated and misinterpreted, but are referred to some absurdly unreal cause, as to the presence of a serpent in the stomach, or to a galvanization of the nerves, or even to those cases in which the patient supposes his legs to be glass, his body butter, or himself metamorphosed into a wolf. By this declension, hypochondriacal melancholy undoubtedly passes into true melancholia.

Sensibility is commonly much affected in melancholia. There may be a general diminution of the sensibility of the skin, or a local complete loss thereof; and complaints of precordial anguish and of strange abdominal sensations testify the perversion of organic sensibility. Illusions and hallucinations of the special senses are frequent: the patient seeing those around him as devils, or smelling a corpse in his room, or tasting poison in his food, or hearing voices which revile and accuse him, or which suggest impious thoughts
and prompt to violent deeds—it may be to imitate Abraham, and sacrifice his child.

The bodily nutrition usually shares in the general depression of tone, although it is sometimes remarkable, considering the great apparent suffering, how little it is affected. When it does suffer, digestion fails, and constipation is troublesome; the skin loses its freshness, becomes sallow, dry, and harsh; the temperature of the body is lowered, and the extremities are cold; the respiration is slow, moaning, and interrupted by deep sighs; the pulse is feeble, sometimes very slow, and even intermittent; and menstruation is generally irregular or suppressed. Sleep is usually deficient, though patients are apt to assert that they do not sleep when they really do, so little do they feel refreshed by it. Refusal of food, which is common, and sometimes very persistent, may be due to other causes besides want of appetite: it may take place through a fear of being poisoned, or in consequence of a delusion that the intestines are sealed up, or in order to commit suicide by starvation, or in fancied obedience to a voice from heaven.

The behaviour of the melancholic accords with, or fitly expresses, the character of his ideas and feelings; and three well-marked groups of melancholia may be made according to the different relations on the motor side:—

1. Melancholia with stupor, *M. attonita*, is interesting because of its close resemblance to dementia, with which it has been confounded. The expression of the face is that of a vacant, self-absorbed amazement, or the fixed form of some painful passion; the patient, as if in a trance, or as one only partially awake, scarce seems to see or hear; there is partial or general insensibility of the skin; consciousness of time, place, and persons is lost, and the bodily wants and necessities are alike unheeded; the muscles are generally lax, or some of them are fixed in a cataleptic rigidity. The patient, who, statue-like, must usually be removed from place to place, is possessed with some terrible delusion, as that the whole world is in flames, or that he is standing on the edge of a sea of blood, and when he recovers his senses he is as one awakened out of a frightful dream. As may easily be imagined, it is not always possible to distinguish this condition from dementia; for as to live in one sensation would be equivalent to having no sensation at all, so for a mind to be entirely absorbed in one terrible delusion, to remain in one persistent state of morbid consciousness, is equivalent, for the time being, to there being no mind at all. As, however, recovery may take place rather suddenly, though it may

* If a person sees, hears, or otherwise perceives what has no existence external to his senses, he has a hallucination; if he sees, hears, or otherwise perceives that which has no such external existence as he perceives, or perceives it with erroneous form or qualities, he has an illusion; and if, though perceiving external objects as they really exist, he believes in the existence of such objects, or conceives such notions of the properties and relations of things, as are absurd to the common sense of mankind, he has an insane conception or a delusion—the ground of the falseness of conception being not error, but a morbid condition.
sometimes last only for a few hours or days and then be followed by a complete relapse, it is plain that melancholia with stupor is different from the stupor of real dementia.

2. Melancholia is often accompanied with destructive impulses to sudden acts of violence against self or against others. Suicidal impulse is very common amongst melancholics, some sincerely and bitterly grieving over the horrible propensity as the sole cause of their unhappiness; but what is very remarkable is the sudden manner in which patients usually calm are at times surprised and overpowered by a desperate impulse and hurried into a convulsive act of violence. A quiet man, having the delusion that his soul was lost, who had been for months under my care, and of whom no one suspected any mischief, suddenly started out of bed one night, without any warning, and flung himself out of a window through which it would have been thought impossible that any man could get. He was possessed with terrible hallucinations, thought that the world was come to an end, and in a fearful state of writhing agony cried—"Let me go! let me go!" Like paroxysms recurred occasionally during the next few weeks, after which the man recovered. In other cases the sudden act of violence may be directed against others; the patient injuring or killing some one by reason of a sudden hallucination, or in consequence of his anguish having reached such a height of unendurable agony as to abolish all self-control, and irresistibly to utter itself in convulsive violence, either against a fancied persecutor or a completely indifferent person (Raptus melancholicus). Of such are some homicidal lunatics. Others act in obedience to a delusion: an evil spirit instigates the demonomaniacs to desperate deeds in spite of the will, or its impulses intensify their misery and lead to determined suicidal attempts, in order to escape from the intolerable promptings. A melancholic mother has killed herself to escape the desperate impulse to kill her child. Nor is it inconsistent with insanity in such cases that the violent deed should have been planned with surprising cunning and effected with sustained ingenuity.

So far from the morbid impulse or act constituting the insanity, it is but the outward and visible sign or expression of a profound affective derangement, the tendency of which is to manifest itself, not as ideational insanity does in words, but in acts, and which for this very reason is much more dangerous than ideational insanity. So far from the disease being simply a homicidal or suicidal insanity, it is truly an affective insanity, one symptom of which is homicidal or suicidal impulse: the delusion, when there is one, and the homicidal act are both symptoms of a deeper lying disease; and the morbid manifestation of one may be as little within control as that of the other, or as the suddenly arising hallucination is. In the one case the patient is the victim of a morbid idea; in the other, of a morbid movement—in both cases, of a convulsion more or less co-ordinated. Where the disease is less acute, it is the feeling of this affective perversion that sometimes drives the melancholic to commit murder in order to be
hanged, or impels a mother to murder her children in order to send them from misery on earth to happiness in heaven. It admits of no question whatever, and should therefore be borne clearly in mind, that the calmest melancholic is liable to periodical unaccountable exacerbations of disease, during the paroxysms of which he may perpetrate violence against himself or others; a wonderful relief, and even an apparent sanity with endeavour to escape penal consequences, sometimes following the accomplishment of the act.

3. There is a melancholia of acute character, with great excitement and restlessness, that may even pass into mania. It is certain that cases marking every step of the transition to mania do occur in practice; and it is not always easy, notwithstanding the painful character of the delusion, to distinguish excited melancholia from mania: there are truly melancholics who are maniacal, as there are maniacal patients who are melancholic. The more activity of movement there is as the expression of the mental suffering, the more acute the utterance of the agony in gesture-language—in the wringing of the hands and the writhing of the body, the nearer does the case approach mania. The manifestations of excitement are, however, generally of a more uniform character than those of mania, and often even monotonous.

The course of melancholia is generally chronic; remissions are common, but complete intermissions rare. Still, it is striking sometimes how suddenly a great change may take place: Griesinger mentions a case of deep melancholia in which there occurred a perfect lucid interval for the space of a quarter of an hour; and I have more than once seen a profound melancholic awake in the morning cheerful and seemingly quite well, remain so for the rest of the day, and yet be as bad as ever on the following day. Such sudden recoveries are, like sudden conversions, greatly to be distrusted. When recovery really takes place, it is usually gradual, and from within four to twelve months from the commencement of the disease; it is rare, but not impossible, after a year. Half, or even more than half, of the cases of melancholia get well under proper treatment; and of those which do not recover, about half decline into mental weakness or complete dementia—the rest remaining chronic or ending in death. Death may be caused directly by the exhaustion of excitement or refusal of food, or it may be due to intercurrent disease, phthisical, cardiac, or abdominal. Gangrene of the lung was found by Guislain most frequently in melancholics who had died after long refusal of food.

Mania.—In this form of mental disease there is an excitement or exaltation of the self-feeling of the individual, the expression of which takes place either in the movements and conduct or in the character of the thoughts. Accordingly, two groups of cases may be broadly distinguished, although they pass insensibly into one another and are not unfrequently mixed: the first including all those cases of acute mania or maniacal fury in which the madness is mainly manifest in
the actions of the patient, who sings, dances, declaims, runs about, pulls off his clothes, and in all ways acts most extravagantly; the second group including those more chronic cases in which the derangement is expressed in the ideas, is systematized in definite delusions—in which, therefore, the morbid action has taken deeper hold of the individual. The first group corresponds in the main to acute mania, the second to monomania.

It was held by Guislain that a stage of melancholic depression, of greater or less duration, almost invariably precedes an attack of mania; and there can be no doubt that this sequence is traceable in very many cases. But it is not so in every case, as some have maintained. What has been commonly overlooked is, that there is not only an affective disorder of a depressed or melancholic kind, but that there is also an affective Insanity which is rather of an excited, expansive, or maniacal kind—a deep derangement of the affective life, in which the individual's self-feeling is greatly exaggerated or morbidly exalted, without positive intellectual alienation. It is a maniacal disorder, so to speak, of the feelings, sentiments, and acts, without delirium; and it is expressed, as the corresponding affective melancholia is, not in delusion, but in the conduct of the patient. As it is from the affective life that the impulses of action come, while the function of the intellect is to guide and control, it is in strict accordance with reason that, when there is affective derangement or perversion of the mental tone, the morbid impulses that arise should be beyond control or guidance of the will, just as the convulsion of a limb is beyond control when there is derangement of the tone of the spinal centres. This inceptive maniacal state, which may unquestionably be primary, though usually following that of melancholic depression, is displayed in a great change of moral character; the parsimonious becomes extravagant, the modest man presumptuous and exacting, and the affectionate parent indifferent to his family; there is an extreme liveliness of manner, or a restless and busy activity, as of one half intoxicated; an overweening self-esteem is a marked feature, and an extravagant expenditure of money or an excessive sexual indulgence is common. Or the exaltation may be less and the perversion of the affective life more marked; in other words, the moral alienation more extreme, as witnessed in the profound moral derangement which sometimes precedes a series of epileptic fits, or takes the place of an epileptic fit, and in most of those cases included by Pinel under mania sine delirio and by Prichard under moral insanity. In such cases, as with the cases of so-called irresistible homicidal or suicidal impulse, it has been too much the practice to fix attention exclusively upon the extravagant actions of the patient, to the neglect of the profound affective derangement out of which his acts spring; so that they have been set apart as special and their real relations overlooked. They are truly of the same nature as that maniacal perversion of the whole manner of feeling sometimes forerunning an outbreak of mania; and their morbid expressions in single acts of vicious or violent conduct,
are of the same kind as those general symptoms of acute mania which are exhibited in the movements or actions of the patient.

Acute Mania; Maniacal fury or frenzy; or Raving Madness.—It seldom breaks out without a preceding stage of affective derangement, the period of incubation being usually of a melancholic character, as though a painful forefeeling of the coming storm. After a shorter or longer period of such premonitory depression there follows a marked change in the inclinations, habits, and affections: the patient, "much, much different from the man he was," gets restless, and is prone to wander or travel about, is sleepless at night, or is tormented with very vivid dreams; he next becomes lively and excitable, as though half intoxicated, and the tone of his voice is sometimes strangely altered; his actions are restless, extravagant, and turbulent; and all the while he thinks himself wonderfully well, and scorns the suggestion of medical aid. As matters become worse there is an irresistible propensity to utter the internal commotion in outward gestures, acts, or words: the patient sings, dances, declaims, shouts, and laughs; or he is industriously occupied in restless and aimless work, as in polishing the floor with his saliva, in tearing his clothes into shreds, or in changing the place of every piece of furniture about him; or he explodes in furious outbursts of rage and raving of word and action. The organic appetites or instincts come markedly into the foreground, the veil of reason being withdrawn: the appetite is ravenous and indiscriminate, garbage, or even excrement, being devoured with apparent avidity; and the patient, forgetful of decency, and abandoned to the promptings of the sexual impulse, masturbates as the monkey does, without shame or restraint. Withal there is often a certain consciousness of his state, so that he may restrain himself and seem reasonable for a time, and when seemingly at his worst he will sometimes yield to the show of energy and determination. The mood of mind may be brisk and humorous, or bitter, angry, and scornful in the face of opposition. There is no fixed delusion, nor any fixed group of delusions; but the ideas are rapid, confused, and transitory, and appear as fleeting delusions, or immediately utter themselves in automatic impulses to words and actions: the idea of an act, the moment it arises in the mind, becomes the act. Because of the rapidity of the flow of ideas in the early stages, the witty observations, acute comparisons, and fluent rhymes then sometimes made, it has been said that there is an increase of mental power. But it is only the semblance of an increase: though there is a lively revival of the past with great vivacity of expression, there is no due assimilation of the present, but an incapacity to perceive rightly the relations of things around, together with false judgment with regard to them, so that the unhappy sufferer is extravagantly joyous in a madhouse; there is an entire absence of that co-ordination of the feelings and ideas which marks the highest mental power and is the condition of true will. The lively flow of scarce coherent ideas marks the excitability of an irritable weakness,
and is the forerunner of a restless succession of isolated ideas and fragmentary associations in the more advanced stages, not otherwise than as convulsion is the forerunner of paralysis.

It is striking how complete in some cases may be, during the attack, the memory of the past, and, after the attack, of all that has happened during it; whilst, in other instances, the patient will forget altogether the events of his madness, like as a dream is forgotten, though he may remember them again during a subsequent attack. It may happen also that, immediately before a second attack, thoughts and feelings displayed on the occasion of a first attack, but latent since, will recur, so that even attendants recognise the evil presages, and can predict the outbreak.

Hallucinations of the different senses are common in mania, and illusions still more so. In 178 out of 229 cases Briere de Boismont professes to have met with such complications; they are generally fleeting, like the other morbid phenomena. Some have thought that the long endurance of the great expenditure of energy in acute mania is owing to a perversion of the muscular sense, by reason of which the true condition of the muscles is not declared. There can be little doubt that illusions of the muscular sense are at the root of the delusions with regard to bodily movements sometimes exhibited in mania; when a person lying in bed believes his limbs or himself to be flying through the air, it is certain that the muscular sense does not give correct information, but is affected with hallucinations.

The bodily functions often bear the great mental agitation of acute mania in a surprising manner. The pulse may be a little quicker in the early stage, when there is perhaps some febrile disturbance; but it is afterwards scarce raised in frequency. The temperature of the body is only slightly increased; but in cases of a typhoid type, where there is sleeplessness, restlessness, gradual wasting, and where the tendency is to death from exhaustion, Dr. Saunders has found it to be often raised from three to five degrees above the natural standard.* In the Insanity occurring after acute diseases, Dr. Weber's observations show only a slight increase of temperature, although this had been raised several degrees during the previous disease, and immediately rose again on the occasion of a relapse.† The skin may be either dry and harsh, or moist and of offensive odour. Constipation is common, but in some cases there occurs a continued and obstinate relaxation of the bowels. The urine Dr. Sutherland found to contain an excess of phosphates in acute mania; and if this were true, it would testify, like the increase of temperature, to an abnormal disintegration of tissue. More recent examinations of the urine, by Dr. Addison, result in the assertion that "the quantities of the urine, of the chloride of sodium, of the urea, phosphoric and sulphuric acids, excreted during the course of a maniacal paroxysm, occurring in acute

* Report of the Devon County Asylum for 1864.
mania, epilepsy, general paralysis, melancholia, or dementia, are less than the amounts excreted in an equal time during health."

The course of mania is not often regularly progressive; there are generally remissions, and sometimes complete intermissions, or even so-called lucid intervals. The attacks may return at regular or irregular intervals, and thus constitute a periodic or recurrent mania; or attacks of melancholia may alternate with them, and give rise to what the French have described as folie cirénaire, or folie à double forme. The duration of an attack of mania may be for hours or months, and recovery may be sudden or gradual. There can be no question of the occasional occurrence of a short maniacal fury, a furor transitorius, lasting for a few hours or days, usually associated with vivid hallucinations, and comparable to an attack of epilepsy.† When recovery takes place, it is usually within the year; it is rare after two years; and, indeed, the longer the disease lasts, the worse is the prognosis, which is always unfavourable in recurrent mania and in mania alternating with melancholia. Recovery not taking place, the disease passes into chronic mania, or into dementia, or ends fatally. Death may be due to exhaustion, or to some intercurrent disease, such as pleurisy or pneumonia. When maniacal exhaustion proves fatal, it sometimes does so very suddenly and unexpectedly, so as to leave in the mind an anxious feeling of doubt whether a more energetic treatment might not have prevented death, or, if energetic treatment has been employed, whether that has not had something to do with hastening the fatal issue.

When the acute symptoms of mania have subsided, and the disease has become chronic, it presents most varied characters, according to its cause and the degree of mental degeneration. When there is considerable intellectual power apart from the delusions, as there usually is when the disease has been produced by moral causes, then the case may properly fall under monomania; when there is great loss of mental power together with delusions, as there often is when the disease has followed acute mania or a physical cause, then it may properly fall into one or other of the groups of dementia. On the one hand, then, chronic mania runs insensibly into monomania; on the other, into dementia. It is remarkable in some cases how much intellectual power may co-exist with extravagant delusions: a person who fancies that not an event in Europe happens which has not some hidden relation to him, who detects a plot against himself in the meeting of a cabinet, or in the journey of an emperor to his country palace, may yet have an exact knowledge of all his affairs, and be capable of giving a good opinion with regard to them. But what such a person cannot be depended on to do, is to control his conduct.

INSANITY.

Monomania; Partial Mania; Partial Insanity; Notional or Delusional Insanity.—The exalted self-feeling which in acute mania uttered itself chiefly in turbulent action gets embodied in a fixed delusion, or in a group of delusions, which fails not still to testify the overweening self-esteem. As in melancholia the feeling of oppression of self was condensed into a delusion of being possessed with a devil, or otherwise afflicted, so here the exaggerated self-feeling is clothed in a corresponding delusion of power or grandeur, and the personality of the patient is transformed accordingly: he would fain have us believe that he has resolved the most abstruse problems of science, that he has devised an infallible scheme for reforming the world, that he is king, prophet, or divine. Monomania is, then, a partial ideational insanity, with overweening estimate of self, and fixed delusion or delusions upon one subject or a few subjects, apart from which the patient reasons tolerably correctly. Pathologically it represents a systematization of the morbid action in the supreme cerebral centres—the establishment of a definite type of morbid nutrition in them. Having regard to the mode of origin of the delusion, the deep hold which the manner of its genesis proves it to have on the individual nature, it will be seen how erroneous it is to speak of the mind being sound apart from the delusion. As in melancholia so here, there is a fundamental affective disorder incapacitating the individual from a just appreciation of those things that really affect the self, that touch to the quick those genuine feelings revealing his innermost nature and instigating his conduct; and he is liable at any time to outbreaks of fury, which, like the delusion, are but expressions of the deep-rooted derangement. The mind is not unsound upon one point, but an unsound mind expresses itself in a particular morbid action. Patients thus suffering often seem calm and harmless enough under the regular discipline of an asylum; but if they are exposed to the excitement of ordinary life, seriously crossed in some project, or subjected to the stress of adverse events, they are liable to outbursts of uncontrollable rage or of true mania; so that one who may have been hitherto only interested by their harmless delusions, will be horrified at the utter madness which they exhibit.

The particular delusions of the monomaniac differ according to his occupation in life and the degree of his culture, and are frequently coloured by the events, social, religious, or political, of the epoch: Esquirol, for example, boasted that he could write the history of the French Revolution from the character of the Insanity which accompanied its different phases. Hallucinations and illusions frequently accompany the delusions which they appear sometimes to generate and always to strengthen. The behaviour of the patient accords with the character of his delusions: one makes sweeping plans and projects, enters upon vast speculations, and sometimes goes through an immense amount of patient and systematic work in perfecting some marvellous scientific invention; another reveals in gait and manner the exalted
character of his delusion; and to a third, ordinary language does not suffice to express the magnificence of his ideas, and he invents new and mysterious signs, which, unintelligible to every one else, have wonderful significance for him.

The course of monomania, once established, is very seldom towards recovery; for as it is rarely primary, it represents a further degeneration or more advanced morbid action than mania or melancholia, upon which it usually follows. Even when it is primary, the outlook is not much more favourable, for it is then commonly secondary to some fundamental vice of character. Certainly recovery may take place, and the patient awake to sense as out of a dream; and in some rare instances it has taken place after years, especially under the influence of the revolution in the system produced by some intercurrent disease or at the climacteric period. When recovery does not occur, the disease becomes more chronic, lasting as such, or passes into actual dementia: the more the exaggerated self-feeling which inspires the delusion wanes, and the more this, losing its inspiration, becomes a mere form of words, the nearer the case gets towards incoherent dementia. As a general rule, it may be said that recovery does not take place when a fixed delusion has lasted for more than half a year.

Dementia.—It is the natural termination of mental degeneration, whether going on in the individual or through generations; and it is accordingly in the great majority of cases chronic and secondary to some other form of mental disease. Dementia may, however, be both acute and primary, and is then not always distinguished from melancholia with stupor. Its acute form sometimes occurs after an attempt at strangulation, after certain acute diseases, and after a series of severe epileptic fits; and in one case under my observation a masked epilepsy seemed to take this form. As a primary disease, it sometimes follows a sudden and severe moral shock, and is now and then met with in young men and women, obscurely connected apparently with the state of the sexual functions: with these exceptions, dementia is a chronic and secondary disease presenting every possible variety in the degree of mental decay. After the disappearance of a severe attack of acute mania, the effects of the shock are many times visible in a certain condition of mental weakness without actual intellectual disorder: the force of character seems to have been sapped, and the finer moral and aesthetic feelings, which are, as it were, the bloom of culture, are abolished; the physiognomy has lost its highest expression, and the individual produces the impression of a certain childishness. This is one end of the scale of degeneration; but at the other extremity mental power is almost obliterated, the acquisitions of the past being completely razed out, and no interest in the present possible, and the patient leads a mere vegetative life. Between these two extremes every sort of transition is met with in practice, so that it is impossible here to do more than indicate certain prominent types.
Most of the permanent residents in asylums consist of those who, after mania, monomania, and melancholia, have subsided into a chronic state of more or less feebleness and incoherence of mind—the crazy people, who represent the wrecks of these forms of mental disease. Some there are who exhibit a few striking delusions which seem to be automatically expressed; the strong self-feeling which underlies or inspires these in monomania has faded away, and they are no longer full of self-assertion, nor eager, earnest, and consistent in carrying out their plans. The old paths of associations are broken up, and memory is almost abolished; all liveliness of feeling is gone, and there is little or no interest in what is going on around; and the only momentary excitement which occurs is when the fixed delusions are attacked. The countenance no longer expresses any fixed passion; there is a want of harmony, or, as it were, a dislocation of its features, and the most which it manifests is the shivered expression of a passion or the shattered wreck of a smile. There is a corresponding imbecility on the motor side: some can certainly continue their former occupation, or can do a little simple manual work, but there is no systematic correspondence of action to delusions, and there is not unfrequently a useless and busy industry in gathering stones, pieces of paper, and sticks. Strange propensities of all kinds are exhibited, as for example to stand or crouch in a particular corner, to walk backwards and forwards for a certain distance on a particular slip of ground, or to fantastically ornament the person with feathers or flowers. The mood may be one of surly depression, or of more or less exaltation. Hallucinations and illusions of the extremest kind are frequent, and tend to sustain the delusions: one woman has in her belly the whole tribe of apostles, prophets, and martyrs; another lovingly nurses as her child a lump of wood decked in rags; a third person, whose singular movements seem unaccountable, is busy spinning threads out of sunbeams; while a fourth continues the most violent movements of his arms in order to prevent the motion of the universe or of his own blood from coming to a stand. The bodily health is usually good, the patient frequently getting stout as the active symptoms of mania or melancholia subside into the calm of dementia. This group represents for the most part dementia following on monomania.

In another group of cases there is greater external activity, with a more general incoherence or craziness. There are no fixed delusions, although there is evidence in the patient’s incoherent expressions, or in his senseless, parrot-like repetition of certain words, of the wreck of such as existed in the maniacal stage. The senses are open to the reception of impressions, but these do not seem to be further fashioned into ideas. There is sometimes entire indifference to surroundings, together with great insensibility to pain; or there are short violent outbreaks of incoherent passion and fury; or there may be desperate and unaccountable homicidal violence. The predominant mood is different in different cases: some are gay, happy, and prone to laugh and chatter; others are gloomy, weep, and display the
mimicry of sorrow; while others again are malicious, spiteful, and addicted to a purposeless mischief with a monkey-like cunning and persistence. The loss of memory is marked: some have entirely forgotten their former life and their own names, while others, who perhaps forget instantly the last thing said, can reproduce the distant past with fidelity. In the movements of some there is marked feebleness, or the indication of commencing paralysis; while others are restless, agitated, and run about with ceaseless activity. The bodily health is usually good: they sleep well, and eat well, often gluttonously and without discrimination, and are sometimes prone to get fat until an attack of excitement and agitation, to which some are periodically liable, reduces them. The physiognomy is blank and expressionless, especially so when the patient is addressed; it is also prematurely aged. Lastly, there is a group of demented patients, in whom the mind is almost extinguished; who must be fed, moved, clothed, and cared for; who manifest little or no sensibility; whose only utterance is a grunt or a cry; and whose only movements are to rub their heads or hands. Their existence is little more than organic, and if not carried off by pneumonia, tubercle, or some other disease, as they frequently are, they die from effusion on the brain, serous or haemorrhagic, or from atrophy of the brain, or from the effects of accident, to which, through their apathetic helplessness, they are much exposed. The course of secondary dementia is from bad to worse: it is impossible that recovery should take place, although the condition and habits of a patient may be much improved by proper care. Those who suffer from acute primary dementia, generally get well; but, of course, senile dementia, though primary, is beyond the reach of remedy. Death may be due to effusion on the brain, or to atrophy of it, or it is produced by accidental disease, as tubercle or pneumonia.

Moral Insanity.—Under this unfortunate name, Dr. Prichard described cases of real mental disorder in which, without hallucination, illusion, or delusion, the derangement is exhibited in a perverted state of those mental faculties which are called the active and moral powers—the feelings, affections, propensities, and conduct. He never designed that a vicious act or crime, however extreme, should be deemed proof of moral insanity; for he expressly insists on tracing the disorder to certain recognisable causes of disease. "There is often," he says, "a strong hereditary tendency to Insanity; the individual has previously suffered from an attack of madness of a decided character; there has been some great moral shock, as a loss of fortune; or there has been some severe physical shock, as an attack of paralysis or epilepsy, or some febrile or inflammatory disorder, which has produced a perceptible change in the habitual state of the constitution. In all these cases, there has been an alteration in the temper and habits."* In reality, however, this moral insanity is no

*A Treatise on Insanity and other Disorders affecting the Mind. By J. C. Prichard, M.D. F.R.S.
special form of disease, but a variety of that mental derangement already described as affective or pathetic; and briefly to enumerate the varieties of this, all which were confounded by Pinel under mania sine delirio, will best exhibit the nature and relations of moral insanity.

a. There are attacks of derangement in which the moral or affective alienation is very great, and in which the intellect is only secondarily affected through the moral perversion, the patient reasoning very well from the premises of his perverted feelings; he has no delusion unless his whole manner of thought in reference to self be called a delusion. These attacks are often associated with epilepsy, which they may immediately precede, as they sometimes precede an outbreak of mania; or they may occur at periodical intervals for months before actual epilepsy, and sometimes take the place of the true epileptic seizure afterwards; or again, the epileptic fits may cease entirely, and be followed by such attacks of profound moral derangement, occurring at uncertain periods, and perhaps passing into dementia. It is important to bear in mind that they represent a condition in which vivid hallucinations and irresistible impulses of a desperate kind, homicidal or suicidal, are apt to arise instantaneously; that they, in truth, embrace the most dangerous forms of the so-called impulsive insanity—the monomanic instinctive of Esquirol.

b. There is the melancholic depression of the affective life already described, in which the anguish rises to such a pitch as to issue in an explosion of convulsive violence, homicidal or suicidal, no fixed delusion being present. Some of the cases of so-called impulsive insanity are examples of this form of disease.

c. The moral insanity proper of Prichard (monomanic raisonnable, Esquirol) occurs in most instances as the result of hereditary taint, aggravated or not by unfavourable conditions of life. It is a more advanced stage of degeneration than that which has been described as the insane temperament, but it does not reach actual intellectual derangement: the moral feeling being the highest acquisition of human culture in the course of development through the ages, its loss is one of the earliest effects of degeneration. Moreover, it will always be necessary to consider the social condition of any one suspected to have moral insanity, inasmuch as it is in the loss of the social feeling by reason of disease that the alienation essentially consists. If a person in a good position, possessed of the feelings that belong to a certain social state, does, after a cause known to be capable of producing every kind of Insanity, undergo a great change of character, lose all good feelings, and from being truthful, temperate, and considerate, become a shameless liar, shamelessly vicious and brutally perverse, then it is impossible not to see the effects of disease. Friends and relatives may remonstrate with such a one, and punishment may be allowed to have its due course; but in the end, both friends and every one who has to do with him must confess that he is the victim of disease—that his proper place is not the prison, but the asylum. Such moral alienation may occur after previous attacks of
Insanity, after acute fevers, after some form of brain disease, or after injury to the head. After an attack or two of melancholia with suicidal tendency, from which recovery has taken place, the patient is perhaps attacked with genuine moral insanity, which ultimately passes into intellectual disorder and dementia. Or there has been more or less congenital moral defect, and maniacal exacerbations of actual moral insanity, without positive intellectual disorder, take place, dementia following after a time; these outbreaks may occur at puberty, or at the menstrual periods. A moral insanity again is in some instances the first stage of mental degeneration that is produced by self-abuse or sexual excesses; it now and then occurs in consequence of a severe moral shock as the forerunner of more marked Insanity; and it not unfrequently precedes general paralysis. If the evidence from its own nature and causation were insufficient, the simple fact that it is often the forerunner of the severest mental disease, might suffice to teach the right interpretation of moral insanity.

There are certain beings who are truly moral imbeciles, the original defect being due, as in idiocy, to some cause acting either before birth, or during the first years of life. With such moral defect there is often associated more or less intellectual imbecility, though not always plainly so. Some of the notorious gaol-birds amongst the criminal classes belong to this group; and in higher social spheres there are now and then met with unhappy creatures who, from their earliest years, have been addicted to lying, or stealing, or every sort of vicious act—who have been expelled from school after school, the hopeless pupils of many masters, and who finally end in an asylum. They are instinctively vicious or criminal, exhibit a complete moral insensibility, and commonly masturbate; and they sometimes decline into mania and dementia.

Here, then, may conveniently be summed up in a modified classification the various forms of insanity described, idiocy and general paralysis, which yet remain to be described, being added:—

I.—AFFECTIVE OR PATHETIC INSANITY.

1. Maniacal perversion of the affective life. Manía sine delirio.
2. Melancholic depression, or Simple Melancholia.
3. Moral alienation proper, approaching which, but not reaching the degree of positive insanity, is the insane temperament, or the neurosis spasmodica.

II.—IDEATIONAL INSANITY.

1. General:
   a. Mania 
     Acute.
     Chronic.
   b. Acute Melancholia.
2. Partial:
   a. Monomania.
   b. Melancholia. Lypcmania.
3. Dementia
   Primary.
   Secondary.
4. Idiocy.
5. General Paralysis.

In making use of this or any other provisional classification, it should be clearly understood that the forms of Insanity are not actual
INSANITY.

pathological entities, but different degrees or kinds of the degeneration of the mental organization—in other words, of deviation from healthy mental life: and they are consequently sometimes found intermixed, replacing one another, or manifested in successive order in the same individual. There is a strong propensity not only to make divisions in knowledge where there are none in nature, and then to impose the divisions upon nature, making the reality thus conformable to the idea, but to go farther than that and to convert the generalisations from observation into positive entities, and then to permit these creations to tyrannize over the thoughts. A typical case of madness might be described as one in which the disorder, commencing in emotional disturbance and eccentricities of action—in derangement of the affective life—passes thence into melancholia or mania, and finally, by a further declension, into dementia. This also is the natural course of mental degeneration proceeding unchecked through generations. The necessity of describing different forms of Insanity under different names should never lead to a neglect of the real relations which they have to one another as different stages of deviation from that mental life which we agree to regard as ideal or typical.

Idiozy.—It is an arrest of mental development by reason of some defect of cerebral development which is either congenital or occurs soon after birth. It will not appear strange that such defect is not always detectable when we reflect that the development of the brain as the ministering organ of the mental life really takes place after birth, and that an arrest thereof would take place within the recesses of the intimate activity of nervous element to which our senses have not gained access—where the subtlety of nature yet far exceeds the subtlety of human research. Marked imperfections of the brain are undoubtedly often met with in idiots. It is sometimes abnormally small, the general arrest of growth being due either to some condition of defective bodily nutrition, or to a premature ossification of the sutures of the skull and a consequent prevention of the growth which normally takes place actively during the first years of life. While it may be that there is no other defect than the abnormal smallness, it happens much more frequently that there are other anomalies, as hydrocephalus, unequal size of the hemispheres, and deficient development of the convolutions. All degrees of unequal size of the hemispheres have been met with, from that slight difference which is natural to that extreme degree where a whole hemisphere has been replaced by a meshwork filled with fluid. Again, there is scarce a particular part of the brain which has not occasionally been found wanting: the corpus callosum may be defective or absent; there may be a deficient development of the anterior lobes, and a simplicity of the convolutions, such as belong to the lower animals; or the posterior lobes may not extend far enough back to cover the cerebellum, as normally they do not in some monkeys, and in all the animals below
them. Chronic hydrocephalus, apparently primary in some cases, but in many others secondary to the atrophy or defect of brain, is frequent in idiots, and sometimes makes them large-headed: the serous fluid may exist in large quantity within the ventricles without being fatal, and death ultimately occur suddenly from a slight increase of it.* Sclerosis of the brain substance often accompanies atrophy, or defect of development.

The irregularities of the skull in idiocy have been much studied of late. When the development of the brain is simply arrested, the growth of the bone may be arrested also, and then the skull is microcephalic. More often it would appear that owing to some constitutional defect of nutrition the arrest of the growth of the bone is primary, and a premature closure of the sutures takes place, whence follows a narrowing or shortening of the skull. Compensating enlargements thereupon take place in some cases, the growth of the brain being in the direction of least resistance, and increasing the cranial deformity though making the mischief less. According to the suture prematurely closed, and to the amount and character of the compensating enlargement, will be the degree and kind of the deformity, of which many kinds have been described. Virchow has investigated with great care what he calls the tribasilar synostosis, which, occurring at the base of the skull, is the anatomical condition of the skull of Cretinism.

The causes of idiocy are sometimes traceable to parents. Frequent intermarriages in families lead to a degeneration that manifests itself in deaf mutism, albinism, and idiocy; parental intemperance and excess, according to Dr. Howe,† occupy a high place as causes; and the natural term of insanity proceeding unchecked through generations is, as Morel‡ has shown, sterile idiocy. During fetal life great fright or mental agitation in the mother or irregularities and excesses on her part may lead to mental defect in the child. But perhaps the most frequent causes of an arrest of mental development are those which operate after birth up to the third or fourth year: they are epilepsy, the acute exanthemata, perhaps syphilis, and certainly conditions of bad nutrition, such as are produced by overcrowding, dirt, and want. Cretinism is an epidemic idiocy arising out of unknown territorial conditions.

The extremest idiots are destitute of any intelligence whatever; they are apathetic, torpid beings, having a human semblance, whom it is necessary to feed, to move, to clothe, to take care of in every particular; who can attend to nothing, and remember nothing; who cannot speak a word; who grunt, make unintelligible sounds, and are unquiet if their appetites are not satisfied, or mechanically continue

† Report on the Causes of Idiocy.
‡ Traité des Degénérescences physiques, intellectuelles et morales, de l’Espèce humaine, par Dr. B. A. Morel, 1857.
some automatic movement of hand, head, or body. The senses are almost invariably defective or wanting, the sensibility of the skin being commonly very imperfect, the hearing feeble, and smell and taste so deficient or perverted that the most acrid or filthy matters are eaten with indifference. The muscular development shares in the general defect; there are cramps of the limbs, contractions or paralysis of certain muscles, and epileptic convulsions. In Scotland there were, five years ago, 2,236 imbeciles and idiots, of whom 43 were paralytic, 46 hemiplegic, 10 paraplegic, 17 choreic, and not less than 207 epileptic.* In less extreme cases there is evident want of power over the muscles, the walk is staggering and uncertain, the eye rolls vacantly, strabismus is common, the speech is defective, and there is slavering at the mouth. Sexual power is absent in the worst cases, and notwithstanding the self-abuse practised by some idiots, feebleness is in all cases more common than excess.

At the other end of the scale stand the so-called imbeciles, the highest of whom are only a little lower than those simple-minded people not deemed imbecile. The difference again between imbecility and idiocy is only one of degree, so that it is impossible to define it. In all sorts and conditions of idiocy two principal types may be broadly distinguished: one embracing the torpid and apathetic beings, who have usually some bodily deformity, and who give feeble signs of life; the other, those lively and excited beings who, rarely observably deformed, are unquiet and restlessly respondent to a rapid succession of impressions, who shriek, laugh, weep, gesticulate, clap their hands, get into mischief, and sometimes pass by a turbulent declension into true maniacal fury. Even the quiet idiots are occasionally liable to sudden attacks of fury, in which they bite, shriek, scratch, kick, beat their heads against the walls, and in other ways act viciously enough. Special talents or aptitudes of a remarkable kind, for remembering, for drawing, or for music, which seem quite inconsistent with the general character of their intelligence, are sometimes exhibited by idiots whose disease is of hereditary origin.

Esquirol divided idiots into three classes, according to the condition of speech. The first division included those who could use words and short phrases; the second, those who could only utter monosyllables and certain cries; the third, those who had neither speech nor monosyllable. Dr. Hack Tuke† proposes a physiological division of them into, first, those who exhibit only reflex or excitomotor movements; secondly, those whose acts are sensorimotor and ideomotor; and thirdly, those who manifest volition. It is a division which, not perhaps practically available, serves to mark the different degrees of degeneracy. By Griesinger, idiots are grouped in certain types:—1. Well-formed children in which the mental development, which

---

† Manual of Psychological Medicine, by Dr. Bucknill and Dr. D. Hack Tuke.
remains at the lowest grade, is the only apparent defect, the defect not being due to any hereditary, but to some accidental cause of degeneration. 2. The cases in which both bodily and mental development have been palpably arrested: these are the dwarfs in mind and body. 3. The Cretin, or basilar-synostotic type of idiocy or imbecility. Cretinism generally manifests itself a few months after birth, and is frequently associated with bodily deformity and goitre; and it is supposed to be due to some miasmatic influence primarily affecting the growth of the bones of the skull. It is most common amongst the mountains of Switzerland, but is met with sometimes in badly drained places, and now and then sporadically. 4. The Aztec type, consisting of the true microcephalic idiots. 5. The thyroid idiots, who have a sort of resemblance to some animal. Pinel, for example, gives a striking account of an idiot who was very like a sheep in habits and manner; and some idiots irresistibly bring to mind the monkey. Still, however degraded an idiot may be, he never really reverts to an animal type; for he represents a new and morbid type, which, but for the fostering care of higher beings, would speedily be extinguished.

Though idiots can never reach a normal development, their condition in many cases may be much improved by persevering training. The faculties which they do possess may thus be brought out in a remarkable manner, and they be made automatically skilful in certain tasks. When epilepsy has co-existed with the idiocy, and afterwards disappeared, marked improvements may take place. Idiots very seldom attain old age; they are "old in their youth, and die ere middle age," apparently from lack of vitality. In some cases, the disease of brain—atrophy or hydrocephalus—directly leads to death.

**General Paralysis.**—It is a form of Insanity, first described by Bayle and Calmeil, which is characterised by a progressive diminution of mental power, and by a paralysis which gradually increases and invades the whole muscular system. It is far more frequent amongst men than women, and its most frequent cause is intemperance. Two of the best marked examples of this disease which I have seen, occurred, however, in teetotallers, who never had been given to alcoholic excess; but in both there was hereditary taint, and in both there was reason to suspect enervating, though marital, sexual excess.

Much discussion has taken place as to whether the mental symptoms precede the paralytic phenomena, or whether the latter first appear—whether the Insanity is primary, or whether, as Baillarger holds, the paralysis is the primary and main affection, the Insanity secondary and accessory. There can be no question in the minds of those who, unbiased by any theory, simply observe cases, that the mental disorder does sometimes appear simultaneously with the motor disorder; that far more frequently, indeed most frequently of all, the mental symptoms are observed some time before there is any trace of
paralysis; but that in some few cases the paralytic phenomena do pre-
cede by a short period the mental symptoms. In fifty-one cases out
of eighty-six observed carefully by Parchappe, he found the paralysis
and mental disorder to be simultaneous; in twenty-seven cases the
paralysis was subsequent, and in eight the precedence was undeter-
dined. Leidesdorf has related one case in which the earliest
symptoms were spinal; and one or two similar cases have been
recorded.*

The motor symptoms are first witnessed in the tongue, which has
to execute the most delicate and complex movements with so much
precision, and especially in the articulation of words abounding in
consonants, where the most complex co-ordination is required. When
the patient speaks earnestly, he does not articulate exactly, and there is
a certain hesitation or thickness detectable in his utterance; when the
tongue is put out, which is done with some difficulty, there is a fibrillar
quivering of its muscles, but it is not pulled to one side. There is a tremulousness, also, in the muscles of expression when put
in action—especially in those of the lips, which quiver as in one just
about to burst into tears. These phenomena, which are of fatal omen,
may not be apparent at first, when the patient is calm and collected;
but if he has had a sleepless night, or if he is much excited from any
cause, then they become evident. An inequality in the size of the
pupils is often an early symptom, but it is not a characteristic one;
it is sometimes present in other forms of Insanity, and it is not always present in general paralysis. As the disease increases, the
patient’s walk becomes affected: the feet are not properly raised and
firmly put down on the ground; he easily stumbles at a step or
on uneven ground, and if asked suddenly to turn round when walking
straight forward, he will stagger like a drunken man. He may never-
theless be very active in walking, and commonly thinks himself
wonderfully well and strong. Precise co-ordination of movement,
such as is necessary for writing, sewing, and like acquired automatic
acts, is lost. The disease still advancing, the articulation becomes
less distinct, the walk more and more tottering; the knees fail; the
patient frequently stumbles, and finally cannot get up again. At last
the primary automatic or reflex movements fail; the pupils become
dilated, but unequal in size; the sphincters lose their power, and the
patient may be choked by a lump of food getting into his larynx.
Sometimes there are transitory contractions of arm or leg, and a
grinding or gnashing of the teeth is not uncommon. The contractility
of muscles for the electric stimulus is retained.

Cutaneous sensibility is usually diminished in the early stages, and
at a later period it is sometimes lost. Yet there are occasionally
transitory conditions of extreme hyperæsthesia, so that the patient
shrieks out in great agony, or the slightest touch produces reflex
movements or even convulsions. The muscular sense is especially
affected, so that the sufferer, deprived of power of executing all

* Beiträge zur Diagnostik der Geisteskrankheiten. Dr. M. Leidesdorf.
complex and delicate movements, deems himself not less skilful than when at his best state, or, quite paralysed, believes himself to have a giant's strength. The special senses are commonly unaffected until near the end, when smell and taste are diminished or lost. Sometimes, however, the patient has vivid hallucinations in the night: there were glorious visions of angels descending from heaven on ladders of gold in one patient under my care, and an agonizing vision of his own wife in the act of adultery rendered another frantic for a time.

The mental derangement is commonly marked by an exaggerated feeling of personal power and importance. After a brief stage of melancholic depression there is a notable change in the character, manifest in different ways: in one there is great mental excitement, and he is joyously and actively busy with wide-sweeping projects and speculations, indifferent to stern realities, and in all ways eager and ready to accomplish the impossible; in another there is a lack of former energy, and he is painfully troubled about little things, dull and confused in his thoughts, and demented in behaviour; while another exhibits unwarted perversities of feeling and conduct, such as mightily astonish his friends; he breaks out into sexual excesses quite foreign to his usual sober character, or orders numerous articles of jewellery for which he can never pay, or even steals what strikes his fancy. Begin as it may, the mental disorder, when unchecked, generally issues in incoherence and extravagant delusions as to personal power and grandeur: the miserable sufferer who can scarce support his tottering body avers that he has the might and vigour of Hercules; while industriously hoarding up pieces of rag, paper, or glass as articles of value, he will sign a cheque for countless millions, or make an easy present of New York; maintaining that he can command a king to do his pleasure, in the same breath he prays piteously to be allowed to go to his own humble home; or, with sexual power extinct, boasts exultantly that a princess shall be his wife and princes be born of his loins. An extreme loss of memory is in striking contrast with the semblance of exaltation: the patient forgets entirely how long he has been in confinement, or denies angrily that he has a wife, though recognising her gladly when she visits him. In some cases the delusions are of a terrific character and accompanied with great emotional depression; and a day of melancholic depression may now and then intervene in the course of the exalted form. In another variety, of rare occurrence, the mental disorder consists in a regular decline of intelligence—a gradually increasing stupidity from the first. Attacks of great excitement and blind violence frequently occur during the progress of the disease. During them L. Meyer has observed the temperature of the head to be raised, and after them the mental decay is found to have increased. As the disease approaches its end—the end of life—the dementia is extreme, and the face becomes an expressionless mask across which now and then flickers the broken ripple of a smile, or it is fixed in a ghastly, sardonic grin; but even in the last stage of mental disorganization, when the capability of
a distinct delusion is gone, the muttered words are oftentimes about golden carriages and millions of money.

The course of general paralysis is towards death, though not steadily so. Under proper treatment a great improvement takes place in the early stages, and the disease seems to be arrested. Some have thought that actual recovery does now and then take place; and certainly there have been in exceptional cases intermissions of such a length that the disease has lasted for ten years. On the whole, however, it is irregularly progressive, its duration being usually from a few months to about three years. It hardly ever occurs before the age of thirty. In the more advanced stages sudden attacks of loss of consciousness, with epileptiform convulsions, are not unfrequent, after which the paralysis and mental decay are both found to have increased. Dr. Saunders has observed that the temperature of the body in general paralysis is generally one or two degrees below the average, but that it rises during the excesses of maniacal excitement, falling again as calmness returns. During the so-called congestive attacks, again, where there is complete coma or epileptiform convulsion, there is generally a considerable rise of temperature: in one case the temperature was for some time 98°, but it rose an hour after one of these attacks to 105°, and next day to 106°, the patient dying in thirty-six hours from the commencement of the attack.* In the last miserable stage of all, when life flickers before extinction, large sloughing bed-sores form, notwithstanding the best care, and diarrhea or pneumonia hastens the long-expected ending.

DIAGNOSIS.—The diagnosis of Insanity is as difficult in some cases as it is easy in others. Acute mania cannot well be confounded with any other disease, and the only doubtful question in regard to it will be in the event of an impostor attempting to simulate it. He must be a clever impostor, however, who can simulate the wild restless eye, the quick fragmentary associations of ideas, the rapid capricious movements, and the volubility of utterance of acute mania, so as to deceive an experienced observer; nor can he, however skilful, pass days without sleep, and even weeks with only a few hours' sleep, maintaining a constant activity the while, as the maniac does. The skin in acute mania is dry and harsh, or clammy, but the skin of a pretender who tries to keep up the muscular agitation will hardly fail to be hot and sweating. Meningitis will be known from mania by its own positive symptoms—by the premonitory rigors, when they occur, the cephalalgia, the fever, the contracted pupil, and the intolerance of light; by a muscular activity, paroxysmal, not continuous, and by frequent spasms or convulsions; by the acute severity of the delirium and the vivid illusions of the senses; and by its rapid progress either to recovery or death. Delirium tremens will also be distinguished by its characteristic symptoms—the muscular tremors, the peculiar fearful illusions and hallucinations, the cold skin, feeble

* Report of the Devon County Asylum for 1864.
pulse, and white and tremulous tongue. It must not be forgotten, however, that persons who have a strong predisposition to Insanity, or who have been insane, or who have suffered at some time from a severe injury to the head, do sometimes after an alcoholic debauch become truly maniacal for a time. In this condition, which may be of short duration, dangerous hallucinations sometimes arise, and the sufferer may perpetrate crime, not knowing afterwards what he has done: of this a searching investigation of instances can leave no doubt. The result again of continued intemperance, or of a long debauch, is sometimes to produce not a delirium tremens, but a true mania, marked by active and violent delirium.

Chronic mania is most likely to be feigned, and if feigned with the skill of Hamlet, the very elect may be deceived. A vulgar impostor will, however, generally “o’erstep the modesty of nature,” and overact the part in the extravagance of what he says, and in the absurdity or violence of what he does, while he will almost of a certainty fall short of his part in the emotional expression of the maniacal countenance. Having the popular notion that a lunatic is widely different from a sane person, he will entirely fail to understand the character which he wishes to represent, so that an experienced person may detect his ignorance; and believing that he must make a great display in order to produce an adequate impression, he will, like a bad actor, exaggerate and rant, so that any one with insight, though without special experience, may discover his incompetency. He will pretend that he cannot remember the simplest things, that he cannot reckon correctly, and will act extravagantly, and answer stupidly or wrongly, when a real lunatic would act calmly and answer intelligently or rightly; he will moreover show no irritation or anger at the suspicion of his sanity. It may not be amiss to suggest incidentally in his hearing some symptom which he ought to exhibit, and to take notice whether he subsequently adopts the hint. If he refuses to converse, the diagnosis becomes more difficult, and a long observation may be necessary in order to establish it. It is truly astonishing how long an impostor will sometimes persist: one man, whose story Dr. Bucknill tells, kept up the pretence of Insanity for more than two years, and then broke down in his part. Perhaps it would not be far from the truth to say that he who can feign madness so completely as to deceive an experienced observer, is not far from being the character which he represents; for unless there be real madness beneath the feigned phenomena, there will be some want of coherence in them as a whole, and an incongruity with any recognised form of mental disease.

The discovery of chronic mania or monomania where it does exist, but where the patient is suspicious and strives to hide it, may be a very difficult task. There is generally some sign of the disease in the countenance and bearing of the patient: “The principal characteristic in some is,” says Dr. Bucknill, “a peculiar want of harmony in the expression of the features; in others, the fixed expression of
The demeanour may be defiant, sullen, restless, or absorbed, and the clothing untidy and neglected; in both demeanour and dress there are sometimes peculiarities which, when bottomed, open up a secret mine of madness. To detect any delusion, the patient should be examined carefully on all matters intimately touching himself, anything peculiar or notable in his expressions, or any obscure references, being watched for, noted in the mind, and subsequently quietly followed up. If he seems to pass hastily over, or to avoid, some subject, he should be unobtrusively but steadily pressed upon it; and if he declines to speak of the matter, or gets angry, the refusal or irritation is alike significant. All this should be done in as suave, polite, and amiable a manner as possible, so as to avoid giving unnecessary offence, and to make it a difficult matter for the patient to take offence and break off the interview. It is an intellectual contest between a sound and an unsound intellect, in which the weakness of the latter is compensated by its acting on the defensive, the superiority of the former lessened by its acting on the offensive. Heinroth has affirmed, what is popularly thought, that though the insane may often conceal their delusions, they cannot deny them. This is by no means true of all cases: some will deny their delusions with as much energy as Peter showed when he denied the dangerous truth, or will even labour to explain them away as jokes. When all else fails, it may be worth while grievously to offend the patient's self-love, and to make him extremely angry, and in the fury of passion he will sometimes, notwithstanding his suspicion, reveal the hidden delusion. Failure will be rare with the expert, who likes to be persistent and patient enough. In doubtful cases, it will always be well to get the patient to write, for it is truly surprising what extravagant delusions may be exhibited in a letter by one who manages to conceal them in conversation. Careful research should of course be made into the previous history, in order to discover whether there is hereditary taint, and what degree of it; whether there has been any previous attack of Insanity, and whether there has been any observed change of feelings, character, and habits, especially after some efficient cause of Insanity. At the outset a patient sometimes has a suspicion that he may be thought mad, and is very earnest and vehement in accounting for his morbid feelings, and at great pains to convince those around him that he is not mad.*

Melancholia is not usually difficult to recognise, as patients in most cases do not care to conceal their painful delusions; still there are some who not only conceal but deny them. A patient afflicted with homicidal and suicidal impulse, and intensely miserable in consequence, will positively conceal and deny the morbid impulse, in order to throw those around off their guard, and the better to effect his purpose; and more than one such, foolishly removed from under

* There are some excellent observations by Dr. Bucknill on the mode of conducting the examination in the Manual of Psychological Medicine, p. 310.
control by ignorant and well-meaning friends, has afterwards com-
mitted suicide or homicide, or both. Another, who cannot entirely
conceal his disease, will even attribute his depression to the confine-
ment which he is undergoing, and asseverate most earnestly that he
will be quite well at home; this intense eagerness to be delivered
from control being truly the surest sign that he is not fit to be from
under control. In all such cases it is necessary to watch patiently
from day to day; for it will sometimes happen that a delusion, denied
on one day, is predominant on another, and it is very apt to become
so, if the patient does not see a prospect of release through his simu-
lation of sanity.

It may be important to distinguish between the hypochondriac and
the melancholic, as the former, committing a murder, would certainly
be hanged, the latter probably not. The hypochondriac refers his
sufferings to some organic disturbance or disease, in which there may
be more or less reality; he displays an exaggerated sensibility in
regard to all his organic processes, or to some one of them in par-
special, so that he has either many delusions respecting his health, or
his whole habit of thought respecting it is perverted; he is fond of
talking of his sufferings, and of consulting medical men; he evinces
a great love of life, and no disposition to commit suicide; his intellect
is sound, and his feelings are not perverted, apart from questions
touching his health. The melancholic, on the other hand, refers his
sufferings to some groundless extraneous cause, either operating from
without, or having taken possession of body or soul, or both, so that
he has frequently a single and fixed delusion; his anguish is a mental
anguish, and he asserts that medicine can do him no good; he is often
suicidal; his affective life is profoundly implicated, and he is inca-
pacitated from intellectual activity, though there may be no marked
intellectual derangement apart from the delusion. It must not be
overlooked, however, that hypochondriasis may pass into true melan-
cholia, as well as co-exist with it, and that a true hypochondriacal
melancholy may rise to such a pitch as to render the individual
irresponsible for his actions.

Melancholia with stupor may easily be confounded with acute
dementia; nor is it always possible to distinguish them at the outset.
The expression of the melancholic is that of one astonied, or as if
fixed in a painful trance—the mind veiled, as it were, by a great cloud
let down between it and the external world. The patient stands or sits
in one place, or moves slowly to and fro; he often offers a passive
resistance to being moved, or to being fed; sometimes he exhibits a
strong tendency to suicide, and, now and then, a temporary excitemen	on recovery, he remembers his suffering as a painful dream, or as a
strange and fearful trance, during which he was partly conscious of
things around, but unable to express himself. In dementia, the
countenance is expressionless; there is no resistance to being moved,
or to food; the patient is not suicidal; the bodily functions are less
affected; on recovery, there is no memory of the attack.
In certain criminal or civil trials, it may be necessary to distinguish between eccentricity and Insanity. There is a great gap between them: the truly eccentric man has a strong individuality, but little vanity; he has broad and original views, and great moral courage; he is emancipated from vulgar prejudice, and heed's not much the world's blame or censure; he differs from the majority perhaps because he is in advance of the habits and superstitions to which it is in bondage; and he is not at all likely to become insane. But there is a weak affectation of eccentricity which is very apt to end in Insanity: with it are infected certain feeble-minded beings, often badly bred or badly trained, who are empty of any true individuality, but inflated with an excessive vanity; who have a small intellect which they use in the service of their passions; who do silly and eccentric things, not unconsciously as the spontaneous expression of their nature, but out of a morbid craving to attract attention; who represent a condition of mental derangement that is the forerunner of Insanity; who, when they are not given up to sexual excesses, are often masturbators.

In the diagnosis of so-called moral insanity, it is necessary to look for a sufficient cause of mental disease from which the vicious or violent acts may be logically traced through a train of symptoms, such as marked change of character, feelings, and habits. Neither vice nor crime, however extreme, is proof of Insanity. To be so, it must be proved through a chain of morbid symptoms to flow not from passion, but from disease; and attention should not, therefore, be entirely occupied with it, but should carefully traverse the whole affective life, in order to reveal the perversion of nature detectable in a case of real moral insanity, and the connexion of the morbid change with an efficient cause of disease. A man may get into the police-court for stealing, in whom one may perceive instantly the earliest symptoms of general paralysis; another may commit murder, apparently without motive, or from a very inadequate motive, in whom a melancholic anguish has risen to a convulsive explosion; and a third may perpetrate violence in a state of affective derangement, which skilled observation recognises to be premonitory of, or vicarious of, an attack of epilepsy.

General paralysis is easily recognised after it has passed its earliest stage. It is not always easy of diagnosis before the physical signs appear; and yet a man may at this stage get into trouble—get into the police-court, or get married foolishly—entirely by reason of the disease. It is necessary to weigh carefully the character of the act, whether it is anywise explicable, or motiveless and quite unaccountable; to mark well the state of the patient's articulation under excitement or after a sleepless night; and to attend to the great exaggeration and general extravagance of his conversation on all matters concerning himself, even when there is no fixed and positive delusion. General paralytics, in the early stage, speak so extravagantly and absurdly regarding things which they have seen, or events in which they have been concerned, that an inexperienced
person might be apt to put down the whole as a delusion. It is needful to bear in mind, that there may be some foundation of fact in what they say of themselves—that they do not at first so much invent as outrageously exaggerate. It is needful also to remember the alternations of calmness and apparent sanity that occur in the early course of the disease.

Pathology.—Though it may be that there are no morbid changes detectable in the brain of one who has died raving mad, it is none the less certain that, with change of energy, there is a correlative change in the nervous substratum. Nothing is yet known of the intimate constitution of nervous element, or of the mode of its functional action; and it is beyond question, that the difference in its condition may be the difference between life and death, without any appreciable physical or chemical change. As the means of research improve, however, the instances of Insanity in which morbid changes are not found are more and more rare, and those who have most studied the matter are those who are most certain and speak most confidently of the invariable existence of such changes. When a morbid poison acts with its greatest intensity, there are notably fewer traces of structural alteration than where its action has been less intense and more prolonged; and in like manner, appreciable organic changes in Insanity may be justly expected only when the degeneration has been extreme and long continued. Where this has been the case, morbid changes are seldom looked for in vain.

Investigations into the electrical properties of nerves, and into the phenomena of conduction by them, have not only rendered conceivable the existence of important, though undetectable, molecular changes among their ultimate elements, but have proved the necessity of dismissing all metaphysical conceptions of nervous function, and of making positive research into the physical and chemical conditions which, whatever its nature, determine its manifestations. So far from conduction by nerve being due to the instantaneous passage of some imponderable principle, it depends upon some modification of its molecular constitution, for which a certain time is essential; for it has been shown that a definite period of time, varying in different persons and at different periods in the same person, is necessary for the propagation of a stimulus from the peripheric ending of a nerve to its central ending in the brain; and when the stimulus has reached the brain, a certain time must elapse before the will can transmit a message to the muscles, so as to produce motion. No investigation has yet been made of the time-rate of activity of the cerebral centres, but there is assuredly a considerable variation in the time in which the same mental functions are performed by different persons, or by the same person at different times. "The mind in health," says Locke, "will boggle and stand still, and one cannot get it a step forward, and at another time it will press forward, and there is no holding it in." Appreciable and variable,
then, is the time-rate of thought, and the measure probably of that intimate molecular activity which is the condition of its manifestations. That such molecular activity does take place, the "waste" after function proves; the chemical reaction of nerve becomes acid after activity, owing probably to the formation of lactic acid in the retrograde metamorphosis; and the increase of phosphates in the urine, and the bodily exhaustion after great mental work, are only to be explained by supposing an idea to be accompanied by a correlative change in the nerve cells. Here, indeed, is a region of most delicate activity, which, like that of thermal oscillations, or of undulations of light, is yet impenetrable to sense; and so far from its being improbable that undetected morbid changes may exist in Insanity, so far from its being wonderful that morbid appearances are sometimes not found, the wonder truly is, that they should have been expected always. Where the subtlety of nature so much exceeds the subtlety of human investigation, to conclude from the non-appearance the non-existence of change, would be analogous to the blind man asserting that there are no colours, the deaf man that there are no sounds.

Not only have erroneous ideas been entertained respecting the kind of organic change that might suffice to give rise to Insanity, but the nervous element itself, as a living individual entity with intrinsic properties, has been commonly ignored; the main stress having been laid upon the blood-vessels, as if they were the primary agents in exciting and keeping up the mental disorder. The truth is, that the first step in Insanity often is, as it is in inflammation, a direct change in the individual elements of tissue, the change in the blood-vessels being secondary. The experiments of Lister* have proved that in the case of mechanical or chemical injury to some tissue, the individual elements are directly injured, and that a determination of blood, a dilatation of the vessels, and an adhesion of the corpuscles, follow the local mischief; and it is easy to conceive that damage to the nervous element of the brain, however caused—whether from overwork, or emotional anxiety, or from poison in the blood, or by direct injury or reflex irritation—may in like manner declare itself in disordered function, and be accompanied or followed by vascular disturbance. The nervous element is brought to a lower state of life, and manifests its deviation or degeneration from its normal kind by an abnormal or degenerate energy, while the disturbance of circulation takes place as a coincident or sequent effect of a common cause. Where there is hereditary taint, there is innate vice or defect in the constitution of nerve element, and it will accordingly break down more easily under adverse stress. The effects of strychnia may serve to illustrate the presumed course of events: when a dog is poisoned with strychnia there may be no morbid appearances, but if there be any, they are such as congestion of the spinal cord, aneurismal dilatation of the capillaries, and perhaps small effusions of blood into the grey matter.

On the Early Stages of Inflammation, by Joseph Lister, F.R.S.; Vol. xxxi. Philo-

*philosophical Transactions, 1858.
The congestion is plainly a secondary result of the intense morbid activity of the directly poisoned nervous element. Here, then, is the abstract and brief chronicle of the order of events in many cases of Insanity. Transfer the convulsive action from the spinal cells to the cortical cells of the hemispheres, the result is a violent and acute mania in which the acute determination of blood is certainly not the cause, if it be not the consequence, of the degenerate function. In what is called mania transitoria, the patient falls suddenly into a violent fury, in which he raves and often exhibits destructive impulses; his face is flushed, his head hot, and there is plainly an active determination of blood to the brain; and in a short time the fury subsides, and the man is himself again, scarce conscious, or quite unconscious, of what has happened. Was the rush of blood the primary and active agent in the production of the fury? Was it not rather secondary to the intense morbid or degenerate action of the nervous centre—the attack representing a sort of epilepsy, and the congestion taking place not otherwise, than as it takes place in the spinal cord poisoned by strychnia? So in chronic insanity, the congestion discoverable may not be the cause, but the effect and evidence of the morbid action of nervous element. And in those cases of Insanity in which there is no special morbid appearance after death, though there has been fixed delusion during life, it is because the definite morbid action which does exist takes place in that innermost region of activity of individual element, to which our senses have not yet gained access. Only by fixing attention on the individual elements will a just conception be formed of the mode of that degeneration which reveals itself in mental disorder, but at present is not otherwise revealed; and only thus will the morbid appearances that are met with receive their right interpretation.

It would be one-sided and mischievous, in another way, to overlook the fact that disturbances of circulation, of extraneous origin, may directly favour and even produce Insanity. Having regard to the extreme susceptibility of nervous element, and the abundance of the supply of blood to it, there can be no question that the quantity and quality of the blood play a weighty part in the pathology of Insanity.

**Quantity and Quality of the Blood.**—Since the time of Hippocrates, it has been known that similar symptoms are produced by too much and by too little blood in the brain. In that continued active relation between the blood and the nervous element, whereby due reparative material is brought and waste matter carried away, it amounts to much the same thing whether, through stasis of the blood, the refuse is not carried away, and the supply brought to the spot where it is wanted, or whether the like result ensues by reason of a defective blood or a deficient circulation. Now, although temporary irregularities in the cerebral circulation may, and often do, pass away without leaving behind any abiding ill effects, yet when they recur frequently, and become more lasting, their disappearance is by no means the disappearance of the entire evil; they are efficient to
initiate a degeneration, which thenceforth continues of itself and
leads to permanent mental derangement. Once the habit of a definite
morbid action is fixed in a part, it continues almost as naturally as,
under better auspices, the normal physiological action.

A vitiated state of blood, by reason of matters bred in it, or intro-
duced from without, may act perniciously on the supreme cerebral
cells. The rapid recovery which takes place after moderate doses of
alcohol, opium, Indian hemp, seems to show that the damage they
inflict is transitory; but it admits of no question, that when nervous
element is repeatedly exposed to their poisonous agency, it acquires a
disposition to degenerate function. The intense gloom produced by
the presence of bile in the blood, and the extreme irritability pro-
duced by some urinary constituent in the blood of a gouty patient,
serve to show what effects upon the supreme nervous centres may
be due to the non-evacuation of the waste matters of the tissues.
When, furthermore, it is remembered that the blood is itself a living,
developing fluid; that, "burnished with a living splendour," it circulates
rapidly through the body, supplying the material for the nutrition of
the various tissues, receiving the waste matter of their activity, and
carrying it to those parts where it may either be appropriated and
so removed by nutrition, or eliminated by secretion, it is plain that
multitudinous changes are continually taking place in its constitution
and composition—that its existence is a continued metastasis. There
is the widest possibility, then, of abnormal changes in some of the
manifold processes of its complex life and function, such as may
generate products injurious or fatal to the life of nervous element.
Poverty of blood undoubtedly plays a weighty part in Insanity, as
in other nervous diseases; and there is, in the effects of the viruses
of acute fevers, ample evidence that morbid poisons, bred in the
organism or entering it from without, may act in the most baneful
manner on the nervous centres. In some cases of malignant typhus,
and in the putrid infection after surgical operations, the virus generated
is directly fatal to the life of nerve element; and when it acts with
less intensity, it gives rise to the delirium of fever, and predisposes
probably to the Insanity following acute fevers.

Reflex Action, or Sympathy.—The supreme cerebral centres may,
like other nervous centres, suffer secondarily from a morbid centre of
irritation in some other part of the body; though why they should do
so at one time and not at another, we know not any more than why
epilepsy should be caused by an eccentric irritation at one time and
not at another. That they do so, many recorded instances clearly
testify.* When a chronic insanity is brought about in this way, the
delusion has sometimes a relation to the primary morbid cause; the
secondary derangement of the cerebral centres testifying to the
special effect of the particular diseased organ—as, for example, when

* References to such cases may be found in Griesinger's work. There is a remarkable
case also related by Dr. Brown-Séquard in his Lectures on the Physiology and Pathology
of the Nervous System. 1860
a woman, with uterine or ovarian disease, believes she is with child by supernatural means, or, with morbid irritation of the sexual organs, has salacious delusions. There is the most perfect harmony, the most intimate connexion or sympathy, between the different organs of the body, as the expression of its organic life—a unity of the organism beneath consciousness; and the brain is quite aware that the body has a liver or a stomach, and feels the effects of disorder in any one of the organs, without declaring it directly in consciousness. This unconscious, but not unimportant, cerebral activity, which is the expression of the organic sympathies of the brain, receives its most striking illustrations in the influence on the mind of the development of the sexual organs at puberty, and in their subsequent influence on dreams; and it is of great weight in the production of morbid mental phenomena. A just appreciation of its importance will not fail to teach the lesson which a true conception of the organism as an individual whole, formed of differentiated parts harmoniously co-ordinated, teaches also, that every organic motion, visible or invisible, sensible or insensible, ministrant to the highest aim, or to the humblest function, does not pass issueless, but has its due effect upon the whole, and is felt throughout the most complex recesses of the mental life.*

The primary morbid centre, which gives rise to secondary derangement by a reflex or sympathetic action, may not be in a distant organ; it may be in the brain itself. A tumour, abscess, or local softening does not interfere with the mental processes at one time, while it produces the gravest disorder of them at another; and it is not uncommon in abscess of the brain for the mental symptoms, when there are any, entirely to disappear for a time, and then to return suddenly in all their gravity, the derangement or abolition having been due to a sympathetic or reflex action.

Here, then, should be distinguished the different kinds of disorder of the cerebral centres to which a morbid cause may give rise. The sudden appearance and equally sudden disappearance of extreme mental derangement prove that it is functional; it being impossible to conceive the existence of serious organic change in such case. Although, then, the functional disorder necessarily implies a molecular change of some kind in the nervous element, the change may well be one affecting the polar molecules, such as the researches of Du Bois Reymond have proved may rapidly appear and rapidly disappear. At any rate the induction of recognisable transitory changes in the physical constitution and function of nerve by definite experiments, warrants the belief in similar modifications producible by morbid causes which are not artificial, but which are just as abnormal as if they were artificial. This modification of molecular con-

* "Man is all symmetric,
   Full of proportion one limb to another,
   And all to all the world besides.
   Each part calls the furthest brother;
   For head with foot hath private amity,
   And both with moon and tides."—George Herbert.
stitution, which vanishes at first with the removal of the cause, will not fail, if too great or too prolonged, to degenerate into actual nutritive change and structural disease, just as an emotion which alters a secretion temporarily may, when long enduring, lead to nutritive change in the secreting organ.

**Excessive functional activity.**—The display of function being the waste of matter, it is plain that if there be not due intervals of periodical rest, degeneration of nervous element must take place as surely as when directly injured by morbid poison, or mechanical irritant, or as surely as a fuelless fire must go out. It is sleep which thus knits up the ravelled structure of nervous element; for during sleep, organic assimilation restores as statical or "latent" the power which has been expended in function, or made "actual" in energy. Sleeplessness is, accordingly, one of the troubles following intense mental anxiety, or too great mental activity, and forerunning Insanity: that which should heal the breach is rendered impossible by the extent of the breach. Like Hamlet, according to Polonius, the individual falls into a sadness, thence into a watch, then into a lightness, and by this declension into the madness wherein he finally raves. To provoke repose in him is the prime condition of restoration; the power of it "closing the eye of anguish," and healing "the great breach in the abused nature" of nervous element.

Thus much from a pathological point of view concerning the causation of Insanity: it now remains to enumerate the morbid appearances that have been met with in the brain and its membranes.

**Morbid Anatomy.**—The broad result of investigation is, that the morbid changes most constantly met with are such as affect the surface of the brain and the membranes immediately covering it; and of these changes, those in the layers of the cortical substance are the principal and essential. The signs of more or less inflammation of the membranes, especially milky opacities of the arachnoid, are common enough in the bodies of those who have not died insane. But there would appear to be some hindrance to inflammation spreading easily to adjacent parts that are of different structure; whereas, when they are of the same structure, it passes readily from element to element of the same kind, as it were by an infection: the intercostal muscles are scarce affected in acute pleurisy, the muscular walls of the intestines scarce affected in peritonitis, and inflammation takes place in the membranes of the brain, without seriously implicating the cortical layers. If these are involved, there can be no question that the mind suffers. Deaths in the acute stage of Insanity are not usual; but if an opportunity presents itself of examining the brain at this early stage, the morbid appearances are those of acute hyperæmia—namely, great injection of the pia mater, with spots of ecchymosis, and more or less discoloration and softening of the cortical layers, which may be separated easily with the handle of a scalpel from the white substance beneath: the discoloration being in red streaks or stains, with spots
of extravasated blood, and the softening of a violet or pinkish hue; the puncta vasculosa of the white substance are also increased. There are no observable differences between the morbid appearances met with in acute mania and in acute melancholia; and though such fact ill agrees with their different symptoms, it is not entirely singular, forasmuch as alcohol makes one man lively and another melancholic. A differential pathology would involve the knowledge of what constitutes individual disposition or temperament. It must be confessed, that in both mania and melancholia morbid changes are sometimes wanting.

The instances of chronic insanity in which no morbid lesions appear, are rare: the longer the disease has lasted, the more evident they usually are. There is mostly some degree of thickening or opacity of the arachnoid, which may form a white opaque layer through which the convolutions are scarce visible; and many of the more advanced cases exhibit some degree of atrophy of the brain, especially of the convolutions—these appearing shrunk, pale, and anemic, or as if some were wanting and replaced by an effusion of clear serum into the subarachnoid space. The atrophic change may be, according to Dr. Wilks, a simple degeneration, or a degeneration associated with the changes resulting from chronic inflammation. The pia mater is at times adherent to the surface of the brain, so that there is some difficulty in stripping it off without bringing portions of grey matter away with it. This adhesion is not peculiar to general paralysis, as some have thought, though most often met with in it; for it is now and then found in other forms of chronic insanity, particularly in those following epilepsy and drunkenness. The ependyma of the ventricles is thickened, and sometimes covered with fine granulations, such as have been described also by L. Meyer on the arachnoid and inner surface of the dura mater. Dr. Wilks has seen a minutely granular condition of the lining of the ventricles, in a case of acute mania; he has often seen it in epilepsy—once, when the granules were as large as peas, and "the whole surface of the ventricles had very much the appearance of an ice-plant." In some cases, the exudation is in flattened scales or patches.

The morbid changes most frequent in general paralysis, though in rare instances there are scarce any detectable, are great edema of the membranes, adhesion of the pia mater to the grey substance beneath, local discoloration or softening of the cortical layers, or superficial induration of them. More or less atrophy of the whole brain, and particularly of the convolutions, is common, and is accompanied with greater firmness of its substance, enlargement of the ventricles, and serous exudation into them. Diffuse pachymeningitis, effusion of blood into the membranes, or rather into the layers of exudation (Virchow, Rokitansky), and degeneration, atheromatous and calcareous, of the

* Virchow's Archiv. B. xvii. s. 209.
arrests, are not unfrequently met with. Though these changes are more common in general paralysis than in any other form of Insanity, they are by no means peculiar to it, nor are they constant in it; in some cases, the evidence of meningitis is most marked, in others that of atrophy.*

A diffuse albumino-fibroid exudation of low form, gluing the membranes to the surface of the brain, has been declared by some to be characteristic of syphilitic insanity. Instead of being diffused, the gum-like exudation, or syphiloma, as it has been called, may be circumscribed so as to form a tumour, and press into the substance of the brain, causing softening immediately around it; or again, it may be met with as a diffuse infiltration or a tumour within the brain, the membranes being unaffected. At the outset it consists of an exuberant growth of connective tissue, which afterwards undergoes more or less fatty degeneration; and it certainly has not any character by which it can be distinguished as a specific product.†

Researches have been made into the absolute weight and specific gravity of the brain in Insanity, but they have not been sufficiently exact.‡ Dr. Skae and Dr. Boyd found the absolute weight to be slightly increased in the insane, the increase being greatest in mania, and least in general paralysis. The specific gravity is also increased, the lowest specific gravity, which is still above the average, occurring in dementia, the highest in epilepsy. Dr. Bucknill observed that the mode of death influenced the results, and found also that the increase of specific gravity was due, in some cases, to a deposit of an inert albuminous matter amongst the proper nervous elements, and the consequent shrinking of these—a condition seemingly not unlike that since described by Prof. Albers as parenchymatous infarction of the brain, and met with after typhus, in some cases of old Insanity, and in imbecile children, especially those of a scrofulous habit of body. A fibrinous or albumino-fibroid exudation would appear to be a not uncommon result of the degeneration of extreme Insanity; it is the condition probably of the increased consistency, or sclerosis, which is the final result of atrophy; and it is comparable with the product of what is described as chronic inflammation in other organs, as the liver and spleen. A similar exudation is the cause of the so-called hypertrophy of the brain from which

* A compact account of the morbid changes in general paralysis, with exhaustive references, will be found in a paper by Dr. E. Salomon on the Pathological Elements of General Paresis; Journ. Ment. Science, October, 1862.

‡ Dr. Bastian’s recent researches prove that the specific gravity of different parts of the grey matter differs considerably in health. “On the Specific Gravity of the Human Brain;” Journ. Ment. Science, January, 1866.
children sometimes die, and which is now and then met with in single cases of Insanity and epilepsy.

The microscope has of late years added something to our knowledge of the nature of the morbid changes in Insanity. The most constant result has been to establish a rank or exuberant growth of connective tissue, and a coincident or sequent decay or destruction of the proper nervous elements, in Insanity of long standing, and especially in general paralysis. The researches of Rokitansky and Wedl reveal a more or less diseased state of the capillaries of the cortical substance in general paralysis: these exhibit aneurismal dilatations, and tortuosities varying from a single twist to a more complex twisting and even to little knots of varicose vessels. Round the capillaries, small arteries, and veins there is a hyaline deposit of embryonic connective tissue beset with oblong nuclei; this afterwards becoming more and more fibrous, so that the vessel may look like a piece of connective tissue, in which granules of fat or calcareous matter ultimately appear. Other products of the retrograde metamorphosis, such as amyloid corpuscles and colloid corpuscles, are also found in connexion with the hypertrophied tissue, which, whether called inflammatory or not, is itself essentially the result of a vital degeneration. The degeneration appears to be of two kinds: first, there is a defective nutrition, a retrograde nutritive process, whereby the vitality not reaching the height necessary for the production of the proper elements of the structure, there are engendered from the germinal nuclei elements of a lower kind—connective tissue instead of nerve; and, secondly, there is a retrograde metamorphosis of the formed elements of the part—a colloid, fatty, or calcareous degeneration. Be this as it may, there are at any rate three principal stages of the degenerative process: (1), a morbid change in the vessels, whereby there must be a great hindrance to regular nutrition; (2), atrophy of nerve element, either in consequence of the hindrance to nutrition (Rindfleisch †), or from the rank growth of connective tissue (Rokitansky); (3), the increase and subsequent retrograde metamorphosis of connective tissue. Recently it has been asserted by Dr. Tigges, that there is, even at an early stage, an increase of nuclei in the ganglionic cells; the numerous scattered nuclei, usually thought to belong to connective tissue, he considers to have escaped from ganglionic cells at a later stage of their inflammatory degeneration.‡

Such changes are not peculiar, as some have said, to general paralysis; like changes have been described by Wedl.§ in the brains of three

† Histologisches Detail zu den grauen Degeneration von Gehirn in Rückenmark. Von Dr. E. Rindfleisch. Virchow's Archiv. B. vi.
‡ Zeitschrift für Psychiatrie, B. xx. In Virchow's Archiv. 1865, Dr. Franz Meschede has striven to prove that hyperemia and parenchymatous swelling of the inner layer of the cortical substance are the beginning, and fatty degeneration the end, of the organic changes in general paralysis.
congenital idiots, and have been met with in dementia following on long-continued Insanity, and in tabes dorsalis; and there can be little doubt that the morbid product in syphilitic dementia is of a similar nature.

Briefly summed up, then, the kinds of degeneration met with in the brain, after Insanity, are as follow:—1. There is in acute Insanity an acute hyperæmia, or the early stage of inflammatory degeneration. 2. There is that degeneration which consists in the increase of connective tissue, and in the atrophy of the nervous elements, and which might be called connective tissue degeneration. Whether called sub-inflammatory or not, is not of much moment, so long as we keep in mind the true relations of organic element to the supply of blood, and the degenerate nature of inflammation, whether acute or chronic. 3. Fatty degeneration takes place not only in the small vessels, as in atheroma, and in the new morbid products, but also in the broken-up nervous elements, and even in the nerve-cells. 4. The amyloid degeneration is undoubtedly pathological. Wedl holds that the amyloid corpuscles should be ranked along with the so-called colloid bodies, and viewed as the result of an increased exudation, that may take place without hyperæmia. Rindfleisch, on the other hand, believes that he has traced their production from the nucleated connective-tissue corpuscles; while some, like Rokitansky, maintain that the ganglionic cells themselves are converted into colloid bodies. 5. Pigmentary degeneration is sometimes met with. In senile atrophy the ganglionic cells are sometimes richly filled with brown pigment molecules; and, in one case of dementia, where there was partial paralysis of the tongue, Schroeder van der Kolk found the cells forming the nuclei of the hypoglossal nerves in such a state of blackish-brown degeneration that he at first mistook them for little points of blood, but they were filled with granular, dark-brown pigment. It is worthy of remark, that cases of pigmentary degeneration of the retina are often found to occur in the same family, to be accompanied with general defective development, mental and bodily, occasionally with mutism and Cretinism, and to occur in those who, like albinos, are the degenerate offspring of marriages of consanguinity.* 6. Calcareous degeneration is common enough in the hypertrophied connective tissue, and in the small blood-vessels; and it has been observed in the ganglionic cells themselves. Erlenmeyer met with calcified cells in the optic commissure of a monomaniac; Förster figures calcified cells found in the grey substance of the lumbar enlargement of a boy whose lower extremities were paralysed; Heschl found what he calls ossified cells in the brain of a patient who died melancholic; and Wilks believes certain bodies, found in the brain of a general paralytic, in whom the small arteries were calcified, to have been ganglionic cells that had undergone calcareous degeneration. Those who duly weigh the pathological import of the kinds of

* On Retinitis Pigmentosa, by J. Laurence; Ophthlmic Review, No. 5, April, 1865. The observations of Prof. Graefe and Liebreich are quoted.
degeneration enumerated, who reflect on the great gap which there is between a calcareous granule and a nerve-cell in the economy of nature, or between a connective-tissue corpuscle and a nerve-cell in the histological scale of life, must admit that the difference is not less great than that between dementia and sound mental action, and will scarce venture to assert that the morbid appearances throw no light whatever upon the nature of Insanity. Even the comparatively slight signs of hyperæmia are of weighty significance, if their true relations are recognised, if they are viewed as results and evidence of that degeneration of individual nervous element, of which the mental disorder is also result and evidence, if they and the Insanity are viewed as, what they often are, concomitant effects of a common cause.

PROGNOSIS. — Two questions at once present themselves: the first, whether the disease directly endangers life; the second, and perhaps more solemn one, whether there is any prospect of recovery. Respecting the first question, it may be said in general terms that Insanity does certainly reduce the mean duration of life, and much more so in its recent acute forms than in its more chronic forms. Of all forms, general paralysis is the most fatal, other varieties not being, as a rule, directly dangerous to life. Still, certain cases of acute mania and acute melancholia do terminate suddenly in death, owing probably to exhaustion, and it may be utterly impossible to say beforehand whether they are going to do so or not. When the temperature of the body rises several degrees above the natural standard, the prognosis is bad; and any indication of motor paralysis, or any kind of hybrid epileptiform convulsion, in the course of the disease, is of evil omen, while an attack of genuine epilepsy, unfavourable as regards recovery, is not so as regards life. A long-enduring refusal of food may sometimes end fatally, both in mania and melancholia.

What prospect there is of recovery in a particular case will depend greatly upon the cause of the attack, upon its form, and upon its duration. The more recent the outbreak, the better the chance of recovery, the expectation of which from proper treatment adopted within three months from the commencement is about four to one, while it is less than one to four after twelve months' duration of the disease. When the stage of secondary dementia, incoherent or apathetic, has been reached, all hope of recovery is gone. Primary dementia is generally curable.

Of the acute primary forms of mental disease melancholia is more curable than mania, although some have thought otherwise, deceived probably by the experience of an asylum into which simple cases of melancholy do not usually come. After melancholia acute mania is most curable; but when attacks of melancholia and mania alternate, the prognosis is very unfavourable. A day of great depression and weeping intervening in the course of acute mania, is of good omen. When the maniacal fury is subsiding, the prospect
is good if the patient is sad and depressed, begins to inquire about his family, and to show other signs of a return to his former feelings; it is bad if the feelings remain unmoved, and the intellect is calm in its disorder—if, in other words, there is evidence of the organization of disorder. Even the disappearance of intellectual disorder is not a certain sign of recovery, unless there is a return to the old healthy feelings, and the patient recognises that he has been mad. A periodical recurrence of attacks of Insanity, with long intermissions, is of decidedly unfavourable augury; the attacks commonly become longer, the intermissions briefer, and the outlook gets more and more gloomy.

Monomania is far less curable than mania, the fixed delusions marking the establishment of a definite type of morbid action of a chronic nature. Recovery does sometimes take place under the influence of systematic moral discipline, or from a great shock to the system, whether emotional or produced by some intercurrent disease. In melancholia, where there is a fixed delusion that the cause of misery is in some external agency, the prognosis is unfavourable; but it is more favourable in the melancholic who attributes his affliction to his own imaginary backslidings. In like manner the homicidal melancholic, who believes himself the victim of persecution, seldom recovers: the suicidal melancholic, who is not so in consequence of any definite delusion, frequently does recover, especially after some serious and almost successful suicidal attempt.

When Insanity has been slowly developed, the prognosis is more unfavourable than when it has been of sudden origin—this probably being a part of the larger truth, that when Insanity is slowly developed it is produced by the egoistic passions as an exaggeration of some peculiarity of character, as pride, ambition, avarice; but when it is suddenly caused, it is by the shock of an altruistic emotion, as, for example, grief about others. For a like reason a frequent alternation of active symptoms is more hopeful than a steady persistence in a particular group of quiet symptoms. Hereditary insanity is generally deemed most unfavourable, but recent researches prove that it is not so much so during a first attack, although the disease is more liable to recur than when not of hereditary origin. When insanity has been caused by habits of self-abuse or by sexual excesses, the prognosis is unfavourable in all but the earliest stages. If religious excitement purely has been the cause of an outbreak, the prognosis is most favourable; but it is necessary to bear in mind that a form of religious insanity is the vicarious satisfaction of unsatisfied sexual love, that more or less nymphomania is oftentimes associated with it, and that the outlook then is hopelessly bad. When disease of brain, or injury of the head, or epilepsy, has been the cause, the derangement is practically incurable. The prognosis is favourable in hysterical insanity; and it is most favourable of all in puerperal mania. A decidedly bad symptom is a fixed hallucination, as is also a complete preservation of bodily health with persistence of mental disorder: when there is
palpable bodily disorder, as digestive disturbance, anæmia, menstrual irregularity, there is good hope that with the restoration of bodily health the mind may be restored also. The most favourable age for recovery is youth, the probability of it diminishing with the advance of age, and few recovering after fifty: as many as 86 per cent. of males and 91 per cent. of females, attacked with mania under twenty years of age, recovered at the Somerset Asylum. The recoveries amongst women exceed those amongst men, by reason probably of the frequency and fatality of general paralysis among men.

The general conclusion of Dr. Thurnam from his careful statistics is that, "as regards the recoveries established during any considerable period—say twenty years—a proportion of much less than 40 per cent. of the admissions is under ordinary circumstances to be regarded as a low proportion, and one much exceeding 45 per cent. as a high proportion." The liability to recurrence of the insanity after recovery from the first attack cannot, he thinks, be estimated at less than 50 per cent., or as one in every two cases discharged recovered. On the whole, then, he holds that, of ten persons attacked, five recover and five die sooner or later. Of the five recoveries, not more than two remain well during the rest of their lives; the others have subsequent attacks, it may be after long intervals, during which at least two of them die.*

* In an elaborate paper on Vital Statistics and Observations, in the Journal of Mental Science, January, 1865, Dr. Boyd records the statistics of the Somerset Asylum for many years:—

The diseases of the respiratory organs, which proved fatal, were principally pneumonia and phthisis.
INSANITY.

Therapeutics.—The treatment of Insanity is moral and medical, the two methods properly being combined. It must again be individual, as the case is; for the varieties of the insane character demand different moral means, as the varieties of causes call for different medical treatment. It is necessary to penetrate the individual character, with the design of influencing it beneficially, and carefully to investigate the concurrence of conditions that have issued in Insanity, with the object of removing them. Herein lies the chief difficulty of treatment; in no other disease are there so much concealment and so much misrepresentation, witting and unwitting, on the part of friends. It is before all things necessary again that treatment should be begun early, before the habit of a definite morbid action has been fixed; but, though early, it must not be rashly vigorous and energetic, with the aim of effecting any sudden revolution, but rather patient and systematic, in the hope of a gradual change for the better. Whilst in other diseases time is reckoned by hours and days, it must in Insanity be reckoned by weeks and months.

Moral Treatment.—To remove the patient from the midst of those circumstances under which Insanity has been produced, must be the first aim of treatment. There is extreme difficulty in treating satisfactorily an insane person in his own house, amongst his own kindred, where he has been accustomed to exercise authority, or to exact attention, and where he continually finds new occasions for outbreaks of anger or fresh food for his delusions. An entire change in the surroundings will sometimes of itself lead to recovery: if the patient is melancholic, he no longer receives the impressions of those whom, having most loved when well, he now most mistrusts, or concerning whom he grieves that his affections are so much changed; if he is maniacal, he is not specially irritated by the opposition of those whose acquiescence he has been accustomed to, or encouraged by their submission to his whims and their indulgence of his follies. Travelling may be recommended in the early stages, in order to secure change of place and scene; or if the patient cannot travel, he may be removed from his own home to another residence, and systematically treated there. If the pecuniary means do not admit of the adoption of either of these expedients, or if the patient is furious, or desperately suicidal, or persistently refuses food, it will be necessary to send him to a suitable asylum. It must be borne in mind that an insane person cannot, from the very nature of his disease, have his own way, and that to allow him to do so would be directly to aggravate his disease. To put him under restraint in some way, to exercise for him that control which he cannot exercise for himself, is indispensable so long as there is a hope of cure: to let him distinctly understand that this is legally done will of itself have a beneficial effect. The melancholic who finds himself in an asylum finds a real grief to alternate with or perhaps to take the place of his fancied affliction, and the maniacal patient, feeling his wild spirit of exulta-
tion to be rudely checked by the influence of a systematic control, can scarce fail to have more sober reflections aroused.

The patient having been removed from those influences which have contributed to the production of the disease and tend to keep it up, and having been made to recognise from without a control which he cannot exercise from within, it remains to strive persistently and patiently by every inducement to arouse him from his self-brooding or self-exaltation, and to engage his attention in matters external—to make him step out of himself. This is best done by engaging him earnestly in some occupation or in a variety of amusements; and this will be more easily done now that the surroundings are so entirely changed. The activity of the morbid thoughts and feelings subsiding in the new relations and under new impressions, more healthy feelings may be gradually awakened; and the activity of healthy thought and feeling will not fail in its turn further to favour the decay of morbid feeling. It is not by arguing against a delusion or directly contradicting it that any good will be done: it were almost as well to argue against the east wind or a convulsion; but by engaging the mind in other things, and substituting a healthy energy for the morbid energy, this will be most likely to abate and finally die out. But though it is of little use talking against a delusion, it is desirable to avoid agreeing with it: by quiet dissent or a mild expression of incredulity when it is mentioned, the patient should be made to understand clearly that he is in a minority of one.

Medical Treatment.—There is no specific agent in the treatment of any form of Insanity. A truly scientific treatment will be grounded on the removal of those bodily conditions which may appear to have acted as causes of the disease and on the general improvement of nutrition. The morbid sensations, so common in Insanity, do often arise from some real bodily derangement, and tend to keep up the delusion. Now, bodily disease is not always easily detected in the insane; for the usual symptoms are very much masked, and they, like animals, make no intelligent complaint. “Insanity,” says Dr. Bucknill, “is not confined to the brain, and, when it is confirmed, a man becomes a lunatic to his finger ends.” It is necessary, therefore, to pay particular attention to the physical signs of disease: there may be no cough, no expectoration, when the thermometer or the stethoscope reveals advancing phthisis.

General bloodletting is now rarely, if ever, used; even in the most acute and seemingly sthenic insanity it is not simply useless, but it is positively pernicious. Violent symptoms may abate for a time, but the disease is very apt to become chronic and to pass rapidly into dementia. Local abstraction of blood by leeches or by cupping may be useful where there appears to be great determination of blood to the brain; by withdrawing blood from the overloaded vessels the opportunity of rest is afforded to the struggling and suffering nervous element.

The continued application of cold to the head by means of a douche
INSANITY.

pipe, or by pouring cold water upon it, while the patient lies in a warm bath, is often successful in calming excitement and in procuring sleep in acute insanity. The warm bath alone, taken for about half an hour, has a soothing effect, and may induce sleep; and its efficacy has been supposed to be wonderfully increased by the addition of several handfuls of mustard, so as to produce a general redness of the surface of the body. Brière de Boismont professes to get very good results from employing the warm bath for eight or ten hours at a time; and Leidesdorff has used for three or four hours, and in many cases with marked calming effect, a bath constructed by Professor Hebra, in which patients may be kept night and day at a definite temperature. Such a use of the bath must obviously be avoided where the pulse is feeble and where there is anything like commencing paralysis, and it is of no avail in cases of chronic insanity. The prolonged use of the shower bath and of the cold bath, at one time much in fashion, is now justly abandoned. The shower bath or cold douche may certainly be usefully employed in certain cases of melancholia, where reaction does not fail to take place after it, and in cases of chronic insanity with the purpose of rousing the patient and giving tone to the system; but its use should never be continued for more than three minutes, and it should not be with the aim of producing any special effect, but on general principles of improving the bodily health. The good effects of the Turkish bath have been much vaunted by its advocates, but an exact discrimination of the cases in which it is useful yet remains to be made. Packing in a wet sheet has sometimes a beneficial effect, and is commonly rather grateful to the patient.

Counter-irritants are not much used now in Insanity. Schroeder van der Kolk, however, put much faith in the application of strong tartar-emetic ointment, or of a blister to the shaven scalp; and Dr. Bucknill has found it useful to rub croton oil into the scalp in the passage from acute to chronic insanity or dementia, and in chronic melancholy with delusion. Blisters to the nape of the neck appear to have little other effect than to increase mental irritation; and the benefit of setons and issues in the neck is very problematical.

After errors of digestion and secretion have been duly attended to, the diet of the insane should be good; and it will be desirable in most chronic cases, and in many acute cases, to allow a liberal use of wine. There can be little doubt that an attack of Insanity might sometimes be ward off by a generous diet and free use of wine at a sufficiently early stage. It is at any rate a truth worthy of all acceptation, that energetic antiphlogistic treatment in the course of Insanity is energetic mischief. Leeches may be applied to the head, and a patient may be kept on low diet, in order to subdue maniacal excitement, without any other result than an increase of the excitement with the increase of exhaustion; and the most active purges may be given, and given in vain, to overcome an obstinate constipation,—when brandy and beef-tea, reducing exhaustion, will subdue
excitement, and a simple enema will produce full action of the bowels. Active purgation, once so much favoured, is now quite eschewed in all forms of Insanity. The bowels may generically be regulated by dietetic means; and if a purge is needed, a dose of aloes, rhubarb, or castor oil will answer every purpose—a moderate dose of the latter often succeeding where the most drastic purgatives fail. It will of course be necessary to be guided by the bodily state of the patient, and by the history of the causation of the disease, as to whether wine is given or not in the most acute stage; it may be desirable in cases of a sthenic type to do nothing but wait patiently, only preventing the patient from doing harm to himself or others, until the fury of the storm has passed, and then to give support.

Amongst drugs useful in Insanity, opium undoubtedly occupies the first place. It is especially useful in that state of mental hyperesthesia which so often precedes the outbreak of Insanity: when the mental tone is so changed that almost every impression is painful, then opium, freely administered, has virtues which can scarce be exaggerated. When the acute symptoms of mania have just subsided, then, too, is a most favourable time for giving opium. It is most useful, again, in cases of simple melancholia, when it should be given in doses of one, or even two, grains twice a day, and continued steadily for weeks, notwithstanding an apparent want of success at first. In these cases it does not usually produce constipation; but if it does, then each dose may be combined with a grain of extract of aloes or a quarter of a grain of podophyllin. Where there is fixed delusion of some standing, opium is not of much use, except as an occasional expedient for procuring sleep. In the mania caused by intemperance, in the mania or delirium of nervous exhaustion, and in puerperal mania, opium is most beneficial; but it is of little use in melancholia with stupor, in idiopathic acute mania, or in the attacks of excitement that occur in the course of chronic mania and general paralysis.

In cases of great excitement, maniacal or melancholic, where opium does no good, large doses of digitalis sometimes produce the best effects, especially where there is general excitement of the circulation. The excitement abates, and the pulse, falling in frequency, may be kept for a long time at a standard below the average. In the attacks of excitement which occur in the course of general paralysis, the effects of digitalis are excellent; a single dose of two drachms, or continued doses of half a drachm, every three or four hours, being safely given. Hydrocyanic acid may be usefully combined with it; and some entertain a high opinion of the good effects of this acid when given by itself.

The subcutaneous injection of morphia is a valuable expedient to have recourse to, where there is a refusal to take medicine, and in some cases it operates much more effectually than opium taken by the mouth. Not more than a quarter of a grain should be injected to
commence with, and the quantity may subsequently be increased, if necessary. It will be well to have in mind, that neither opium by the mouth, nor morphia hypodermically injected, will always quench the fury of acute mania, and that successive injections of morphia, followed by brief snatches of fitful sleep, have been followed also by fatal collapse.

Hyoscyamus is useful also in some cases where opium does not agree, but it should be given in doses of not less than a drachm to begin with. Bromide of potassium certainly appears to produce good effects in some cases of maniacal excitement, but in others, apparently similar, it seems to have no effect whatever. Tartar emetic will often calm for a time the most furious maniac, through the prostration which it produces, but it does no permanent good, and its employment for such purpose is rather a relic of the old system of quieting a patient by some violent means or other, short of actually killing him. If mercury be ever useful, and not mischievous, in the treatment of Insanity, it is when given in small doses of the bichloride, in cases that are becoming chronic, or where there is a suspicion of syphilis. To administer mercury systematically in general paralysis, as has been done, is as unaccountable in theory as it is undoubtedly pernicious in practice.

In all those cases of Insanity in which tonics seem to be demanded by the state of the bodily health—and they are the majority of cases, at one period or other of their course—iron and quinine may be given; and one of the best ways of giving them is in a mixture containing quinine, the tincture of the sesquichloride of iron, and chloric ether. In some cases it happens that an uncontrollable diarrhoea sets in and carries the patient off, nothing availing to check it: acetate of lead, with opium, and enemata of starch and laudanum, are most likely to be useful.

When Insanity has become chronic, or when fixed delusions are established, there is small hope of special benefit from drugs. The general health being duly attended to, a systematic moral treatment will be best adapted to restore health of mind. Where there is persistent refusal of food, it must never be allowed to continue so as to endanger the bodily health; and if persuasion entirely fail, then the stomach pump must be used to administer food. Those who are suicidal should be carefully watched at all times, and especially so on getting up in the morning, when the thoughts are gloomy, and the desperate impulse is apt to surprise and overpower them. The monomaniac, who has delusions that he is watched continually, or otherwise persecuted, must always be deemed dangerous to others; for at any time he may become so impatient of his sufferings as to make a fatal attack upon his fancied persecutor. Those who suffer from moral Insanity are often very troublesome to deal with satisfactorily; but it will be worth while always to remember, that one unequal to the responsibilities and duties of the social position in which he was born may not on that account be unequal to the relations of a much lower
social stratum. It is not because a person insists on ruining himself that it is justifiable to deprive him of liberty by sending him to an asylum.

ALCOHOLISM.

BY FRANCIS EDMUND ANSTIE, M.D. F.R.C.P.

DEFINITION.—A disease of the general nervous system, induced by continued excesses in the use of alcoholic liquors. It manifests itself usually in a chronic, but occasionally in an acute form. Its characteristic phenomena are muscular tremor and progressive muscular weakness, insomnia, hallucinations of sight and (less commonly) of hearing and smell, busy delirium, diminished or deranged intellectual and moral force, together with dyspepsia, slight jaundice and morning vomiting. In advanced cases there are also paralysis of sensation or motion, or both, convulsions, epilepsy, dementia, and general degeneration of the tissues of the body. Tendency to death slight when the original cause of the malady can be removed. The fatal result is either produced by exhaustion from protracted acute delirium, or slowly brought about by progressive degeneration of the nervous centres, or of some important organ of nutrition.

SYNONYMS.—Alcoholismus chronicus, Delirium tremens, Delirium potatorum, Mania potatorum, Ebrietas, Chronic alcoholic intoxication, Trunksucht, &c. &c. These various names obviously apply to various aspects of the disease accordingly as it occurs in the acute or the chronic forms, between which there was formerly no sufficient distinction made.

HISTORY.—The "history" of Alcoholism, to use the expression in its proper medical sense, is simply the story of the excesses of each individual patient as regards the daily allowance of alcohol, the duration of intemperate habits, and the kind of liquor taken, especially as regards its degree of concentration.

ETIOLOGY.—This part of the subject is extremely complex. The simplest portion of it is that which refers to the exciting causes, and it will be best to dispose of this first.

1. The exciting causes of Alcoholism can be better appreciated at the present time than formerly, because our increased knowledge of the physiological action of alcohol has enabled us to explode some errors of theory which were almost universal in medical writings and popular belief about the disease. The prime source of these errors...
was the general tendency to notice only the more acute nervous affections which are caused by alcoholic excess—namely, delirium tremens, maniacal excitement, and terrifying hallucinations (horrors). These phenomena had been observed to occur frequently, and were believed to occur always in consequence of a temporary abstinence from drink after a course of excessive indulgence. This presumed sequence of cause and effect fitted exactly with the classical denomination of alcohol as a "stimulant," a member of an ideal class of medicaments which possessed the peculiar property of exciting vital function in such a manner that after a longer or shorter period a "recoil" was inevitable, under which the forces of life were reduced below their natural level. The great feebleness which was observed to characterise the acute delirium of drunkards was supposed to be due to this kind of exhaustion from the withdrawal of an accustomed stimulus.

At present our ideas are very different. In the first place it has been abundantly shown by various writers, of whom Ware* was the earliest, that abstinence from drink by no means always, or even most frequently, precedes the outbreak of delirium tremens or of alcoholic mania: on the contrary, these accidents commonly overtake the patient in the midst of his excesses. Secondly, alcohol, in doses which singly are capable of producing drunkenness, and frequently repeated may bring on acute delirium, &c., has been proved to be a true narcotic poison, of the same class as the so-called anaesthetics, chloroform, and sulphuric ether. Given in these large doses, its influence is entirely in the direction of paralysis—suspension of nervous activity; and this suspension of nervous activity (increased by other sources of deficient vital power, which we shall have to notice as incidental to the circumstances of the chronic drunkard) is itself a sufficient explanation of the nervous debility which brings about the delirious crisis. And thirdly, the modern researches which have enabled us clearly to identify a chronic alcoholic intoxication, often reaching over a period of many months or years, have revealed the fact that in the multitudes of instances the acute attack merely exhibits in full development symptoms which had been partially recognisable for a long time previously.

It may now be taken for certain that the phenomena of which we have to treat under the denomination of Alcoholism, are due in the first place to the direct action upon the nervous system of a blood-supply charged with a high percentage of alcohol. If we surround a living nerve (partially dissected from its connexions) with alcohol of a certain strength, we find that it becomes paralysed—i.e. incapable of transmitting impressions—through its affected part; while a very weak mixture of alcohol and water is incapable of producing this effect. Similarly, if an animal absorb into its circulation a certain quantity of alcohol within a given time, the nervous centres and the peripheral nerves become (though in less degree) paralysed. That this effect is,

* Ware, John, Remarks on the History and Treatment of Delirium Tremens. Boston, 1831.
ALCOHOLISM.

at least in part, due to direct action of strong alcohol upon the nervous tissue can hardly be doubted, considering the analogy of the well-ascertained local effect in the above experiment: there is, however, a co-operative cause of no small importance; namely, it has been ascertained by the researches of various observers that the impregnation of the blood with large quantities of alcohol interferes with its absorption of oxygen; it thus becomes unfitted to support healthy nervous functions. Under these combined influences the nervous tissues, and particularly those of the central organs, become more and more unfitted for the performance of their proper functions: and this change progresses with a rapidity proportionate to the strength and frequency of the alcoholic influence. It is counteracted only by one circumstance—the elimination of portions of the alcohol from the system, which goes on by the medium of all the excreting glands, but more especially by the kidneys, the skin, and the lungs. Upon the activity of these organs in performing this task probably depends, ceteris paribus, the impunity of the drinker from the ill effects of the poison upon his nervous centres. Thus it comes to pass that the occupation and many surrounding circumstances of the drinker modify his symptoms in an important manner, as will be noticed more particularly under the head of Predisposing Causes.

It is necessary here to recall the principal facts which are known with respect to the action of alcohol upon the organism. This substance is easily absorbed from the stomach, especially when that viscus is empty. If the dose be moderate and the administration well timed, the effect upon the nervous system is simply that of a restorative stimulant. Sensations of fatigue are dispelled, the mind works more freely, a healthy sense of warmth is diffused through the body, and the arterial system acquires an increased tonicity if it was hitherto deficient in that quality. The latter fact, which is due to the influence of the remedy upon the sympathetic nerves, is capable of being demonstrated in a very interesting and convincing manner. The sphygmograph of M. Marey has the power of accurately representing, by its registration of the pulse-wave, the degree of arterial tonicity present; and by this unfailing test it appears that the small vessels, when relaxed in a condition of fatigue, are brought, by a moderate dose of alcohol, to a proper tension, from which they suffer no recoil. If, on the contrary, the dose has been immoderate, or administered at a time when it was not required, the pulse-waves give a precisely opposite indication—that, namely, which proves that arterial relaxation has occurred; and simultaneously with this the pulse becomes abnormally quick. At the same time other symptoms of a paralytic nature are observed, confined in the first instance to the spinal nerves and to the fifth cranial nerve. The former show their weakness by the occurrence of slight feelings of numbness, and an impairment of muscular sense in the extremities; the latter indicates its affection by the occurrence of slight numbness of the lips. The vaso-motor fibres of the fifth nerve discover their partially palsied condition by flushing...
of the face, congestion of the conjunctive, and lachrymation. The cerebral hemispheres next give notice of the alcoholic influence by the occurrence of intellectual confusion, and the hypoglossi becoming simultaneously affected, the muscular movements of the tongue become difficult, and articulation is impeded. The further stages of drunkenness consist in more or less noisy or sentimental delirium, passing gradually into coma; palsy, more and more complete, of voluntary motion and sensation; the medulla oblongata is palsied, and breathing ceases; and, last of all, the organic nerves of the heart become incapable of performing their functions, and cardiac life ceases. During all this process the secreting glands are affected, but in varying degrees; the kidneys in particular are singularly little acted on in some cases, and very strikingly in others; and the diuresis, which is the result of the latter condition, is the best safeguard against fatal results, as it involves a large elimination of alcohol. MM. Lallemand, Duroy, and Perrin were the first observers who clearly proved the elimination of unchanged alcohol, and the phenomena appeared to them so striking that they concluded, too hastily, that the whole amount of any dose of alcohol taken into the system was thus eliminated by one or other secreting surface. The facts adduced by these authors do not, however, justify any such inference. I have repeated their observations with much care and especial attention to the dose administered—a point singularly neglected by MM. Lallemand, Duroy, and Perrin. The result of these observations is that a moderate dose (e.g. a pint of light beer or a glass of sherry) produces very slight effects in the way of elimination, which last over a few hours only, and cannot be reasonably supposed to represent the elimination of more than a small fractional part of the alcohol imbied. On the contrary, when a dose has been taken sufficient to produce more or less profound intoxication, alcohol is so copiously eliminated by skin, lungs, and kidneys, especially the latter, that there is some reason to think that as much as from a fourth to a third of the dose taken leaves the body in an unchanged condition within the course of forty-eight hours. Even in this instance, however, there is no sufficient reason to suppose that all the alcohol leaves the body in an unchanged form; indeed there are the strongest reasons for thinking the reverse. It is true that the intermediate compounds, between alcohol on the one side, and carbonic acid and water on the other, which would represent the stages of transformation of the former into the latter, have not yet been satisfactorily proved to exist in the organism after a dose of alcohol has been taken; but in truth nothing like an efficient search has yet been made for them. The researches of Lallemand show us that elimination may go on for a period of forty-eight hours, and my own experience appears to indicate with certainty that not a trace of elimination of unchanged alcohol can be detected at a later date than this. But this is entirely contrary to what we know of the behaviour of those poisonous substances which are wholly eliminated in an unchanged form, especially when, like alcohol, they are of a low diffusive power.
According to the analogy drawn from such cases, alcohol, were it entirely eliminated in an unchanged form, ought to be traceable by the delicate chromic acid test in all the secretions for a period not of two days, but of two weeks or more, from the time of its ingestion. Probabilities are therefore greatly against the total elimination of alcohol in an unchanged form, even from the chemical point of view; and to conclude this part of my subject, I may say that probabilities are converted into what most persons will be inclined to consider certainties, when the remarkable physiological influence of alcohol in supporting vital power is taken into consideration. But as I have dwelt fully on these matters elsewhere, it is unnecessary to repeat facts which would take up a great deal of space in the telling. *

The exciting causes of Alcoholism may be understood, then, to be the repeated direct action of blood strongly impregnated with alcohol on the tissue of the nervous centres and branches, rendering them physically incapable of the due performance of their functions, and the influence of an insufficiently oxygenated blood-supply consequent on a morbid condition of the blood-corpules.

2. The predisposing causes of the disease are much more complicated. They should be divided, in the first place, into (a) those which are occasional, and (b) those which are constant.

(a) The occasional predisposing causes include those external circumstances which expose persons to the temptation of drink, and those internal sensations, produced by temporary illness, which bias them in a similar direction, or, by weakening the nervous system, render the effects of drink more sensibly felt.

Occupation is an important influence. For instance, a large number of cases present themselves at the hospital which are directly traceable to the frequent presence of the temptation, as in the case of workmen at breweries and distilleries, and the potmen and waiters at taverns. In a higher grade of life, public-house keepers and the clerks and travellers for wine and spirit merchants are especially liable to Alcoholism. There is, however, by no means such a preponderance of cases due to this direct temptation as might be supposed. A very large number of patients come from the classes whose business exposes them greatly to the inclemency of the weather; thus cab-drivers, coal-porters (especially the workmen who lade the river barges), and hawkers are very commonly large drinkers; they very frequently become the subjects of Alcoholism, and would be still oftener affected in this way were it not for the assistance to elimination which their out-door life renders. Monotony of occupation is also highly predisposing, especially when combined with much confinement in close rooms. Amongst occupations of this kind there are none which have furnished me with so many and such serious cases as the trades of shoemaker and barber. The want of active out-door exercise, of course, represses elimination and much increases the evil.

* The reader is referred for ampler information to the papers of M. Baudot, in the Union Médicale for 1863, and to my work on "Stimulants and Narcotics." London, 1864.
I have seen few more desperate cases of Alcoholism than some which have occurred in barbers who have been habitually confined to miserably small shops, and at the same time have earned enough money to pay for a great deal of drink.

Depressing Mental Influences are powerful predisposers to drinking habits, and besides this they directly increase the liability of the nervous system to be affected with symptoms of Alcoholism, in virtue of their weakening operation upon it. There is a vulgar notion that drink is the simple and uncomplicated cause of the greater number of crimes committed by the poor. The truth is that, in recognising the indisputable fact that drunkenness is often followed by crime of a worse kind, people are apt to overlook large portions of the history of the criminal, and especially the wretched poverty in which he is usually reared. The demoralising influence of this poverty is the central fact on which we ought to concentrate our attention; it is a common cause of general reckless behaviour, of which drunken habits are only a part, although they doubtless render the commission of fresh crimes more probable. The same recklessness of despair has often been seen to produce intemperance in drink, where poverty had no share in its origin. In the higher classes we not unfrequently see men who have failed in some cherished speculation, or women who have lost the only object which they cared about in life, taking to drink with an almost insane vehemence, although they may never have shown any such tendencies before. It is not that there is any particular temptation in the taste of the drinks to which they have recourse, for it is a fact that even the most refined and delicate women, when they take to these practices, altogether neglect the really fine-flavoured alcohol compounds: they do not drink wine, for instance, but brandy, or some equally coarse and strong spirit. In truth, it is an accident which leads them to select alcohol: under other circumstances they would take opium or hashish, or any other intoxicant which came conveniently to hand, or they would plunge into the indulgence of some special vice which promised them excitement. They merely wish for oblivion. And this is the very motive which drives the poor in many cases to drunkenness, and which simultaneously inclines them to commit other rash and criminal acts; the wish to escape, in any direction possible, from the hideous dulness of a life which is one monotonous pain. Starvation—actual severe deprivation of food—cannot be an active predisposing cause of drunkenness; for the opportunity of getting liquor is cut off by the extreme degree of poverty which brings about such a state of things: it is rather the sense of embarrassment and misery, consequent on the difficulty or impossibility of paying debts, that is common in the lowest ranks of the middle class, which prompts to drinking habits.

The influence of various forms of disease in predisposing patients to Alcoholism is twofold. In the first place, there are many conditions of chronic weakness and suffering which are susceptible of great relief, when they are at their worst period of aggravation, by the use
of alcohol; and this fact, accidentally learned by the sufferer, is from ignorance often perverted. The diseases of this class which are the most important are the whole group of neuralgic, the depression and faintness attending the menstrual period of some women, and the debility and low spirits which often distress nursing mothers. Under the influence of such disorders patients are extremely apt to use alcoholic drinks recklessly, and the foundation of drunken habits is thus laid. This subject is so important that I may be excused for dwelling on it, at the risk of a digression, because it is scarcely possible in a very few words to convey my meaning without danger of being misunderstood. It is frequently charged upon those physicians who recommend alcoholic stimulants in disease, that they are encouraging patients to indulge in one of the strongest temptations to drunkenness. This accusation is entirely unjust, if applied to those who administer the remedy on scientific principles. I have endeavoured to show elsewhere, that it is the use of doses which are large enough or ill-timed enough to produce symptoms of *narcotism* that can alone implant in the patient that craving for drink which forces him against his will to indulge, with constantly increasing intemperance, in the abuse of alcoholic liquors. But the ignorance of the layman who attempts to regulate his own medicinal use of alcohol frequently leads him to confound two radically distinct modes of operation, by either of which this substance may be made to relieve pain and nervous depression or restlessness. The use of such moderate quantities as fall short of producing any, even the earliest, of the *intoxicative* symptoms which have been already described, while it frequently relieves the patient's distress, leaves no disastrous after-depression or craving, but simply restores the nervous system to its healthy state. But pain and various other forms of malaise may also be relieved by the use of true narcotic or *intoxicant* doses which paralyse the nervous system for a time; and it is this kind of temporary relief which involves depression, and a sense of craving for stimulants during the period in which the drinker is recovering from his narcotic stupefaction. It is this wasteful misuse of alcohol, in the absence of scientific knowledge, which becomes a predisposing cause of drunkenness in the case of patients affected with the class of maladies to which I have now referred.

One special variety of chronic temptation to drink, depending on temporary bodily conditions, deserves more notice than it has yet received, but can be only briefly indicated here. I refer to the influence of the sexual orgasm which distresses particular individuals of both sexes (but especially females) in whom the development of puberty takes place in a difficult or irregular manner. The symptoms with which young females are affected under these circumstances are commonly treated (as "hysterical") by various household remedies, which contain more or less alcohol, such as sal-volatile, eau-de-Cologne, and various warming tinctures. These remedies are often swallowed in most improper and unnecessary quantities; and there is too much
reason to believe that in this way the foundation of secret drinking is not unfrequently laid.

(b) There is another kind of predisposing cause, which is constant in its operation, and which is probably at least as influential, both in producing alcoholic excess, and in aggravating its ill effects, as any of those occasional causes which have been enumerated—viz. a peculiar inherited constitution of the nervous system. In the course of a large experience of Alcoholism among the hospital out-patients, I have been greatly struck with the number of drinkers who have informed me that their relations, either on the paternal or th. maternal side, have also been given to drink. And a still larger number are found on inquiry to come of families in which some nervous disorders (especially insanity, epilepsy, and neuralgia) have been markedly prevalent. The doctrine of the hereditary transmission of a neurosis which, according to the special pressure of external circumstances, may take the form either of intellectual insanity, of impulsive emotional impulsiveness, combined with moral weakness, or, on the other hand, of convulsive or neuralgic affections, has been much insisted upon by recent alienist writers, and especially by Moreau in his very able treatise on "Psychologie Morbide." My own experience has led me to a firm conviction that particular causes of nervous degeneration affecting individuals do very frequently lead to the transmission, to the offspring of those persons, of an enfeebled nervous organization which renders them peculiarly liable to the severer neuroses, and which also makes them facile victims of the temptations to seek oblivion for their mental and bodily pains in narcotic indulgence. I believe that things often work in a vicious circle to this end; and that the nervous enfeeblement produced in an ancestor by great excesses in drink is reproduced in his various descendants with the effect of producing insanity in one, epilepsy in another, neuralgia in a third, alcoholic excesses in a fourth, and so on. Among the higher classes, where it is easier than in the case of the poor to obtain tolerably complete family histories extending over two or three generations, careful inquiry elicits facts of this kind with surprising frequency. So strong is the impression left on my mind by what I have observed in this direction, that I am inclined to believe that the great majority of the more inveterate and hopeless cases of alcoholic excess, among the higher classes, are produced by two factors, of which the least important is the circumstances of external momentary temptation in which the patient has been placed, while the more momentous and weighty cause is derived from an inherited nervous weakness which renders all kinds of bodily and mental trouble specially hard to be borne. It need hardly be remarked that, in this view of the case, the fatal rapidity with which habits of intemperance exaggerate themselves is only what might be expected, seeing that the nutrition of the nervous centres would be still further impaired by each successive indulgence in poisonous doses of alcohol, and the power of moral resis-
ALCOHOLISM. 71

tance to feelings of depression and misery would be proportionately weakened.

SYMPTOMS.—The symptoms of acute Alcoholism are in general well known, and there is little difficulty in understanding their access and the order of their succession. What is far less generally understood is the slighter and more chronic form of Alcoholism which, in the majority of cases, precedes by a considerable time the occurrence of the delirious affection. Accordingly, it will be well to commence with the description of this chronic disease, since its characters may be properly considered as representing the earlier stages of a great constitutional malady.

(A) Symptoms of Chronic Alcoholism.—It is upon the motor nervous system that the influence of chronic excess is first discernible in the largest number of cases. Of an extremely large number of patients who present themselves at the out-patient department of Westminster Hospital suffering from this disease, certainly more than two-thirds, upon careful analysis of their complaints, state that a muscular inquietude, which might or might not amount to actual tremor, was the first disagreeable symptom which they noticed. In cases of gradual access the affection at first may amount to no more than an inability to keep the limbs of the body still without a special effort of attention—the exercise of the will being sufficient to render the muscles perfectly steady. This degree of motor disturbance is distinct from and independent of the peculiar mental restlessness to be presently noticed as arising somewhat later, although the occurrence of the mental affection very much aggravates the tendency to involuntary movement. This distinction is noticeable in relation to the nocturnal state of the patients. Long before the occurrence of terrifying dreams, of nocturnal delirium, or of hallucinations—even before there is conscious nocturnal disturbance of the mind at all—the patient feels an inability to sleep which appears to depend on the condition of the motor nervous system. Repeatedly I have been assured by persons suffering from the slighter degrees of Alcoholism that they go to bed with a sense of at least average drowsiness, but an invincible disposition to turn restlessly from side to side in the bed entirely prevents them from getting any sleep.

It is not very often that a patient asks for advice at the early stage of the disease, which is represented by the presence of the above symptoms only. More commonly he does not come under medical notice till the motor disorder has reached a further stage; and his complaint is now, probably, that he suffers from persistent muscular tremor. This symptom develops itself first in the extremities. Magnus Huss declares that it always appears earliest in the hands; but it is probable that this is a mistake, for in a majority of the cases which have come under my care the lower extremities were first affected; but it is less easy to detect tremor of the lower than of the upper extremities, and the former often escapes notice for some time after its commencement.
Huss notes correctly the fact that even in the stage of persistent alcoholic tremor the patients can at first, by a strong effort of the will, restrain their movements for a time, but on the cessation of the effort the tremulousness is ordinarily worse than ever. A very old and general observation is to the effect that the tremor of Alcoholism is almost invariably worse in the morning, and it has been usual to assign as the reason for this, that the accustomed stimulus of alcohol has been withheld for some hours. The statement is plausible, because it is the fact that a glass of beer, or wine, or brandy, taken under these circumstances, will at once diminish the unsteadiness of the muscles; but another fact may be mentioned which strongly opposes the theory—viz. that common foods, such as bread and milk, or broth (if the stomach be not too much irritated to digest them), will answer precisely the same purpose. In truth, the excessive morning tremor of the chronic toper is due chiefly to exhaustion from failure to get sleep. What sleep he has had has been of an unrefreshing kind, and a complete condition of nervous prostration naturally results, from which he can only be rallied by food or drink.

Coincidently with the establishment of persistent muscular tremor, and sometimes earlier than this, certain cerebral symptoms present themselves. One of the commonest of these is a buzzing or a rushing sound in the ears, which is frequently, though not always, accompanied with dull diffused headache. Vision is also affected, with varying degrees of severity, the most trifling symptom being the appearance of muscae volitantes, or of "clouds," before the eyes. Flashes of light are a more serious phenomenon, and their occurrence at night, just before the patient drops into his first uneasy half-slumber, is frequently the immediate precursor of the more definite visual hallucinations. Momentary attacks of vertigo are common. By this time the peculiar alcoholic insomnia is fully developed in the great majority of cases: the patient tosses from side to side during nearly the whole night, getting only broken snatches of sleep, and these almost always attended with disturbing, and often with frightful, dreams.

The mental condition is now usually such as to distress the patient and to impress the medical observer who sees the case for the first time. Its chief feature is the uncertainty of purpose which the sufferer displays: independently of any fixed delusion, or even of a distinct feeling of terror, there is a mental inquietude which makes it impossible for him to settle to any ordinary occupation, or to complete the tasks which he begins. To this is often added a feeling of positive dread which may be vague and unaccountable, or (in bad cases) may arise from actual delusions, such as the belief that an enemy is constantly lying in wait to inflict an injury, &c. This sort of delusion is not to be confounded with another kind, which consists in a vivid apprehension by the patient that he is in danger of falling down a precipice even when he is walking on firm ground in broad daylight, and which seems to me to be connected with rapidly pro-
gressing impairment of muscular co-ordination. Cases which display the latter feature are commonly of a dangerous type, and unless energetically treated, pass rapidly to a hopeless condition as to recovery. The sensation as described to me is not like that of ordinary vertigo, or of fainting; it resembles the disagreeable nightmare which everyone has experienced on first falling asleep after an indigestible supper, or, still more closely, the hideous feelings which some persons (myself among the number) suffer from under the action of a large dose of Indian hemp. But it is not usually found among the earlier symptoms of Alcoholism.

The above is a fair description of the nervous symptoms under which the patient commonly suffers when he first applies for relief. The disorders of common sensation which are frequently produced by alcoholic excess are, in my experience, usually later in their advent. When the patient comes under notice, he may present either of several conditions as regards his outward appearance. There is not often, at this early stage, any very great emaciation, even in the case of habitual spirit-drinkers; but there may be every degree of fatness, from the unwieldy bulk of the country publican, who chiefly fuddles himself with beer, to the slight frame of the London hairdresser, who too often makes away with two or three quarter-martins of gin or rum daily. It is a great mistake, however, to push so far, as is often done in descriptive works, the contrast between the respective influences of spirit-drinking and beer-drinking. The haggard wretches whose portraits Hogarth has drawn in his picture of "Gin Lane" are emaciated to that degree quite as much from utter want of all the comforts of life as from the direct influence of spirit-drinking; and, in fact, one sees, in the classes whose circumstances are a shade more easy, plenty of gin-drinkers who (living chiefly on gin) have a good allowance of fat, if not of muscle. The countenance of the drinker (whether of spirits or beer) usually presents two remarkable features in conjunction—viz., great flabbiness of the muscles of expression, and red, watery eyes: the conjunctivæ are also very generally more or less jaundiced. To this is often added redness of the nose and cheeks, and an eruption, resembling acne rosacea, around the nose and the mouth. On inquiry we learn that, besides the already described nervous symptoms, the patient suffers from morning vomiting, or at least nausea. This is nearly always the case, but there may be any amount—or no amount—of general symptoms of gastric or intestinal irritation, except this one symptom; and the tongue, in correspondence with these variations, may be in nearly any state, from perfect cleaness and moistness to dry red glaziness or thick yellow furring: the latter is its more common condition, especially at the back part. The morning vomiting is in my opinion not a mere dyspeptic disorder, but a true part of the nervous phenomena of receding narcosis. One symptom, which it is not easy to explain, but which nearly always exists, even where there are no signs of dyspepsia, is a peculiar foul breath-smell, which it is impossible to describe, or to mistake when
once it has been smelt. It is quite unlike the odour of the alcoholic liquor itself, and may be separately distinguished even when the latter is also present.

Considering the enormous quantities of spirituous liquors which are drunk by many of the patients who apply for relief from the consequences of chronic Alcoholism, it would be natural for the reader, who holds the usual opinion as to the origin of cirrhosis of the liver, to expect that serious symptoms, produced by the latter disorder, must often complicate cases of the former. The case, however, is far otherwise, in my own experience. Of an immense number of patients in whom the nervous disorder has been clearly identified, I have only seen thirteen cases in which the symptoms of cirrhotic disease called for any special treatment, although a certain degree of cirrhosis was doubtless present in many of the others; and I cannot avoid the conclusion, that some very powerful element, over and above the influence of alcoholic excess, is needed to produce the severe type of that disease. To a less, but still a remarkable, extent, the same observation holds good for kidney diseases of the degenerative kind. With regard to these disorders, I am convinced that other depressing influences must bear a large share of the blame ordinarily attributed to alcohol. How is it possible to form any other opinion, when of the multitudes of drinkers whose kidneys must be daily eliminating large quantities of alcohol, so few present any characteristic change of the urine, or other recognisable symptoms of renal mischief? Be this as it may, it is certain that renal, and still more hepatic, complications are very rarely the source of serious embarrassment in the treatment of chronic Alcoholism of the ordinary type which is indicated by such a group of nervous symptoms as is above described.

Not to anticipate unduly what will have to be said under the head of Prognosis, it may be stated here that the form of the disease, which we have so far considered, is decidedly curable, tending in fact to right itself on the simple adoption of a plan of complete abstinence from the exciting cause of the mischief, combined with a nourishing and supporting diet, unless in the rare instances where sundry complications, which may fairly be called accidental, happen to receive a dangerous development. These complications arise out of the local irritant action of the more concentrated alcoholic liquors on the gastro-intestinal mucous membrane or on the air-passages, and will now be described.

The irritant effects of alcohol on the alimentary canal are chiefly seen in the case of spirit-drinkers, and more particularly in those who drink spirits neat, or highly concentrated. Beer-drinkers do, indeed, often suffer from a simple form of dyspepsia, and there is little doubt that slow degenerative changes are usually set up in the stomachs of these patients; but, except in the case of enormous habitual excesses, the dyspepsia is a transient phenomenon, which rapidly disappears on the adoption of a rigid plan of abstinence, together with a simple medicinal treatment. The more concentrated alcohols, however, when
used for any length of time, may set up a formidable irritation, which produces intense congestion of the stomach or the intestines, or both: in short, a greater or less portion of the tract in which the radicles of the portal vein take their rise is subject to severe engorgement. Perhaps the most serious consequence of such an action is the occurrence, which we now and then witness, of *profuse haemorrhage* from the stomach or bowels. According to what I have seen, this is rare. I have not met with a dozen cases of this kind altogether: two of these, one a case of haematemesis, and the other of intestinal haemorrhage, occurred in the same week, in the practice of Westminster Hospital, quite lately. It is a frequent thing, however, for drinkers to be affected with haemorrhoids, from which more or less bleeding takes place.

Great numbers even of the heaviest drinkers never develop any further *specific* symptoms of Alcoholism than those which have been already described, and their vicious habit, if it shortens their lives, does so chiefly by impairing their general nutrition, and thus rendering them less able to resist the attacks of intercurrent acute disease, and at the same time more predisposed to constitutional maladies, such as gout, for instance, to which they may chance to have a hereditary bias. Others suffer from attacks of delirium tremens (to be presently described), once and again. But in many other drinkers the nervous symptoms, still preserving a more or less chronic type, assume a far more serious development, and we have now to speak of these more extreme developments of chronic Alcoholism.

Of the earliest symptoms which indicate a dangerous degree of nervous degeneration, the occurrence of marked sensory paralysis is one of the most frequent. Unlike the corresponding affection of the motor nerves, sensory paralysis is most commonly exhibited in a slight degree in the upper extremities before it appears in the lower. The occurrence of any considerable degree of sensory palsy in the lower limbs is a sign of grave import: the patient so affected, unless he be induced at once to adopt a proper abstinence, and an appropriate medicinal treatment, is almost certain very quickly to experience some serious organic lesion of the brain. Simultaneously with the occurrence of a considerable degree of sensory paralysis, there is usually a great development of the muscular tremor, which, in several cases which I have seen, approached closely to the type of paralysis agitans. The mental powers are by this time usually affected in a marked degree—the most common mental condition being one of general intellectual enfeeblement and moral degradation, marked by cowardice and untruthfulness. At this point the progress of the case may diverge in either of several directions. In patients whose family history is strongly marked with the taint of insanity, a tendency to suicide is often developed, or else the sufferer sinks rapidly into a state of confirmed and incurable dementia. In others the function of muscular co-ordination is interfered with to a degree which makes the
case resemble, at first sight, the affection known as Locomotor Ataxy. In others there occurs a sudden break down of nervous fibres in the corpora striata, or optic thalami, which produces a stroke of hemiplegic paralysis. In others, along with some symptoms of mental alienation, a general motor palsy is so distinctly observed as strongly to suggest the idea of commencing general paralysis of the insane. In others the rupture of a cerebral artery leads to an effusion of blood and the sudden occurrence of an attack resembling ordinary apoplexy. In others, again (but this is a very small class), the patient suffers attacks of convulsions indistinguishable from those of simple epilepsy. Epileptic attacks, occurring in this way, as a symptom of a very advanced stage of the nervous degeneration developed by chronic Alcoholism, are broadly distinguished, in a clinical and prognostic point of view, from the much commoner attacks of epilepsy in a subject known to be predisposed to or actually affected with that disease, as a mere consequence of a somewhat unusual alcoholic excess; the latter are of comparatively slight consequence, while the former indicate an altogether hopeless phase of alcoholic degeneration of the nervous centres. They are almost always accompanied by an advanced degree of dementia.

(b) Symptoms of Acute Alcoholism.—If we set aside the case of common drunkenness, as being rather an instance of narcotic poisoning, to be dealt with by toxicologists, than a morbid affection coming under the definition which we have placed at the head of this article, we may describe the symptoms of acute Alcoholism as presenting themselves under four principal forms—namely, Delirium Tremens, Acute Mania from drink, Acute Melancholia from drink, and Oinomania.

1. Delirium Tremens.—The clinical history of this disease was much misunderstood in former times. It used to be believed that in the majority of cases the delirious affection was produced, not by the direct poisonous action of alcohol upon the nervous system, but by the circumstance of an habitually intemperate person's leaving off the use of his accustomed potations. As a matter of fact it had frequently been observed that the sufferer from delirium tremens had ceased to drink for one, two, or three days before the access of his more acute symptoms, and the exhaustion caused by the loss of his ordinary stimulant was supposed to produce those symptoms. Dr. Ware, of Boston (1831), was one of the first writers who pointed out that this statement includes a fallacy of observation. From an analysis of 100 cases, he proved that the cessation of drinking, where this occurs, is in fact produced by a feeling of revulsion to strong liquors, which is a part of the early symptoms of the acute disease in many cases; and, on the other hand, that very many patients do not leave off drinking at all, but the delirious attack supervenes in the midst of a debauch. This observation has been confirmed by Dr. Gairdner, and many other excellent recent writers, and at present the classical theory of ex-
HAUSION from withdrawal of an accustomed stimulus has but few
upholders.

The first warning of the approach of delirium tremens is ordinarily
given by the occurrence of complete insomnia. The patient may
have long indulged to excess in drink, or he may be quite a novice in
intemperance, but in any case a greater debauch than usual has
commonly been perpetrated; and the sufferer finds himself quite
unable to obtain any sleep, or at most can only gain short snatches of
slumber, disturbed by horrifying dreams and visions: and during his
waking moments, even in broad daylight, he suffers from hallucina-
tions of sight which commonly take the form of disgusting or
terrifying objects, such as snakes, insects, monsters, or of armed men
pursuing him with threatening gestures. More rarely he hears voices
denouncing threats, or mocking him: occasionally he experiences
delusive sensations of disgusting smells. Often the occurrence of
distinct visual hallucinations while the patient is awake is the first
sign of the passage from chronic Alcoholism (which may have lasted
for months or years, with a varying degree of insomnia, and perhaps
with habitually distressing dreams) to the acute affection. During
the first day or two days the patient is in an extraordinarily depressed
state, with slow and feeble pulse, cold extremities, and a profuse
sweating. The mental state is one of great anxiety, but there are
usually no real delusions: even where visual hallucinations are
present, the patient can by an effort of the will recognise them as
such, and momentarily banish them from his sight. During all this
time there is so complete an absence of appetite, in the great majority
of cases, that no food, or scarcely any, is taken, and this circumstance
probably mainly conduces to precipitate the onset of the second
stage. In this the mere anxiety and nervousness is exchanged for
incoherence of speech and wild excitability of manner, which some-
times takes the shape of causeless anger (though even then nearly
always mixed with cowardice), and sometimes of great terror, which
the sufferer often accounts for by pointing to imaginary terrific shapes
which seem to people the room, and which he is constantly seeking
to push aside with a restless motion of his hands. He talks inces-
santly, in a rambling fashion. Even when his terror or his anger is
at its height he can generally be momentarily restrained by the
influence of any onlooker who addresses him in a firm and determined
manner, and may even be reasoned temporarily out of his halluci-
natory imaginations. The pulse has now become quick (from 100 to
130 or 140 a minute); it is sometimes small and thready, sometimes
soft and voluminous; but in every case which I have examined it
gives a tracing, by the use of Marey's sphygmograph, in which the
form of the pulse-waves closely resembles that which is observed in
fevers and inflammations of a typhoid type, and is especially remark-
able for the prominence of the phenomenon called "dicrotism." The
annexed tracings will give a more accurate idea of the quality of the
pulse than any description of the sensations which it communicates to the finger:—

Muscular tremor, which, from its striking prominence in many cases, has given the disease its name of delirium tremens, is by no means universally present. According to Craigie, whose observations on this point I believe to be correct, they are usually observed in the cases of confirmed dram-drinkers; and in many instances I have found on inquiry that they were only an exaggeration of a tremulousness of the extremities which had already existed for months or for years. But even where the characteristic tremulous movement of the arms and hands is not present there is a constant restlessness; the patient shifts constantly in the bed, and will get out of it twenty times in an hour if he be permitted to do so. The eyes are in almost constant movement; the pupils are usually, though by no means always, dilated. The temporal and carotid arteries throb violently in most cases; very often the face is flushed, but sometimes it remains deadly pale; nearly always there is much sweating, which is obviously due, in great part, to the constant muscular movements. The tongue is protruded, on the request of the physician, with an almost choreic jerk. It almost always trembles; usually it is covered with a yellowish fur, but it may be clean, red, and glassy on the one hand, or brown, dry, and cracked on the other.

It is usual to assign a limit to the second stage (which may last one, two, or several days) at the period when the patient first falls into continuous slumber, and no doubt the classical descriptions which assign this as the critical event to which convalescence may be expected to succeed, find a considerable superficial justification in clinical facts. But, in common with some of the most careful observers, I believe that to be a very erroneous and mischievous opinion which ascribes to a few hours' sleep anything like a distinctly curative power. It is true that in many, perhaps most, instances, the patient awakes, after his first sleep of considerable duration, in a condition of comparative convalescence. But, on the other hand, numerous cases have been observed in which the patient has sunk into profound slumber for many hours, and has awakened as delirious
as ever, or in a state of complete prostration, which has rapidly terminated in death. Interesting considerations will be brought forward on this point, under the head of Prognosis, particularly with regard to the condition of the pulse, and the amount of success which has attended the efforts of the attendants to get the patient to take nourishment. In fact, the occurrence of sleep, even of considerable duration, marks with accuracy the commencement of convalescence only where we find the patient, on waking, clear in his intellect, free (or nearly so) from hallucinations, and with a pulse greatly reduced in frequency and yielding a sphygmographic trace such as will be presently described. The stage of convalescence, once established, presents nothing particularly worthy of description. But instead of sleep occurring at all, the patient may pass from mere delirium into a comatose condition, with muttering delirium, eyes open, staring, and fixed, restless movements of the limbs more marked than ever, picking at the bed-clothes, or possibly profound stertorous coma, or violent convulsions, these symptoms being followed speedily by death. In other cases the patient, in the midst of violent delirium, with great excitability, suddenly collapses, as it were; the pulse becomes hurried, intermittent, and thready; the features pinched and ghastly, the breathing gasping, and death ensues in a minute or two, sometimes even in a few moments.

2. Acute Mania from drink presents symptoms which, though sometimes puzzlingly like those of simple delirium tremens, can usually be discriminated from the latter. The patient, who (invariably, as far as my experience goes) possesses some hereditary predisposition to insanity, is seized, in the midst of a drinking bout most commonly, with active maniacal delirium of a violent kind, and frequently displays a marked tendency to homicidal acts. In most of the cases which I have seen the whole aspect of the countenance and manner of the patient is different from that of delirium tremens, and there is comparatively little of the busy tremulousness of the hands so often seen in the latter disease. I believe that cases which are attended with positive intellectual delusion are nearly always of this, or else of the melancholic kind. The pulse, whatever its degree of apparent strength or weakness, as tested by the finger, is seldom so markedly dicrotous as in delirium tremens.

3. Acute Melancholia from drink presents the usual characteristics of melancholia from any other cause, but is marked by a special tendency to suicidal acts. The influence of a sound, protracted slumber, which in mania from drink is usually very beneficial, is far less so in melancholia from the same cause, as far as my limited experience goes.

4. Oinomania.—The fourth variety of acute Alcoholism is that curious affection which Roesch was the first to describe with precision, and which is now commonly called oinomania. It is, in truth, rather a variety of constitutional insanity than of alcoholic disease; but as the outbreaks owe many of their characteristic symptoms to the
influence of drink, the disorder requires notice in a treatise on Alcoholism. The sufferers from otonomania are, I believe, usually descended of families in which insanity (and often insanity of the same type) is hereditary. Patients of this class very commonly, though not always, display their tendencies early in life; sometimes, indeed, on the very first occasion on which the opportunity for the free use of strong drink presents itself. It should be clearly understood that the term "monomania," which is often applied to the disease, very imperfectly describes the condition of the victims. Closer investigation of their mental state will usually discover the fact that they are liable to periodical recurrences of causeless exultation and bursts of self-confidence on trifling occasions; they then display great obstinacy, and a marked excitement of the animal passions generally: indeed the commencement of a drinking bout is often accidentally precipitated by the circumstances of temptation in which they are placed by loose company. Under the influence partly of an uncontrollable impulse, and partly of intoxication, they will perform truly insane acts; they take useless and purposeless journeys to remote places, or they lose their usual sense of decency, and expose themselves to disgrace by public acts of a degrading character. They exhibit symptoms which in many respects resemble those of simple delirium tremens, though there is usually a marked absence of that anxious terror which is almost always present in the latter complaint, and also a far less decided incapacity to sleep; indeed, there is sometimes very little insomnia. After lasting for a few days, a week, sometimes even a month or six weeks, the attack seems to wear itself out, as if rhythmically; and the patient generally recovers very rapidly his usual health, though he suffers "horrors" for a day or two. The condition of these patients in the intervals between these attacks is very different from that of the ordinary confirmed sot. Very often they live perfectly sober and chaste lives, and are even remarkable for active and intelligent management of their affairs. But this condition only lasts for two or three months, or six months, or at most a year, and then the old symptoms recur, and the patient is uncontrollably hurried into excesses of the most violent kind. Very rarely indeed is a sufferer from this disease really cured; it usually recurs with increasing frequency throughout life, and frequently ends in declared and permanent insanity.

Diagnosis.—The diagnosis of alcoholic diseases of the nervous system is not unfrequently surrounded with difficulties, especially in the case of the chronic forms. Chronic Alcoholism produces nervous symptoms which are particularly liable to be confounded with the following diseases:—1, Chiefly with commencing general paralysis; 2, with paralysis agitans; 3, with lead-poisoning; 4, with locomotor ataxy; 5, with hemiplegia or paraplegia from ordinary softening of the brain or spinal cord; 6, with epilepsy; 7, with senile dementia; 8, with hysteria; 9, with the
nervous malaise associated with some forms of dyspepsia. The
general group of leading symptoms whose presence enables us to
affirm the diagnosis of chronic Alcoholism rather than that of any
of these diseases is as follows:—The patient suffers from restlessness
of mind (without delusions), insomnia, muscular fidgetiness, or actual
tremor, morning vomiting; and presents flabby features, and watery
eyes, and slight jaundice of the conjunctivæ. These symptoms make
the diagnosis highly probable. If to them is added the occurrence
of vertigo, muscae volitantes, and terrifying dreams, it is greatly
strengthened; and it is raised to the point of certainty, in my
opinion, if there be also actual visual or auditory hallucinations in
the form of visible shapes of men, beasts, &c. or audible voices.
Indeed, the concurrence of distinct visual or auditory hallucination
with only four other of the above-mentioned symptoms—viz. in-
insomnia, morning vomiting, muscular tremor, and causeless mental
restlessness—would of itself very nearly persuade me of the existence
of alcoholic poisoning. Cases of commencing general paralysis (the
most embarrassing counterfeits of the disease) may nearly always
be distinguished by the presence of mental exaltation, the condition
of the toper being uniformly one of mental depression, on the whole.
The very rare cases of general palsy which do not display mental
exaltation are wanting in the other features of Alcoholism, unless
indeed when drink has been the exciting cause. As far as I have
seen, chronic alcoholic poisoning always produces three or four of the
leading symptoms which I have mentioned as specially diagnostic; and
where an acne-like eruption of the face is also present, this settles it.
The diagnosis of the acute forms of Alcoholism is usually far less
difficult. We can generally get at a knowledge of the patients' mode
of life in these cases; whereas the chronic toper is very commonly,
especially if a woman, most cautiously and skilfully reticent and
deceitful, and often conceals her habits even from her nearest relations.
A case of considerable difficulty may arise in the distinction between
delirium tremens and some forms of acute mania not caused by
drink. The existence of delusions, not mere terrors, should bias us in
favour of the diagnosis of mania, as should also the tendency to
commit particular acts of violence, and especially lustful propensities;
while the predominance of hallucination, especially when combined
with terror of mind, tremor, and busy delirium, should predispose us
to recognise delirium tremens. For the means of diagnosis between the
different forms of acute Alcoholism the reader is referred to what has
already been said under the heading of Symptoms.

PROGNOSIS.—The prognosis in chronic Alcoholism, except in its
more advanced forms, which are marked by the occurrence of serious
paralytic or convulsive symptoms, or by considerable mental impair-
ment, is highly favourable as regards recovery from the immediate
symptoms. Mere abstinence, combined with simple but energetic
treatment, to be presently described, will suffice in such cases to
procure a rapid removal of all the unpleasant symptoms. Unfortunately too many patients are biassed by long habit, by hereditary constitution, or by the dismally depressing circumstances of their daily life, in a way which renders their return to intemperance indefinitely probable. When once the more serious symptoms—such as paralysis, or epilepsy, or extreme and persistent muscular tremor—have occurred, cure, even for a time, is far more difficult, and the moral degradation of the patient, especially if a female, is so great as to allow small hope that abstinence will be observed.

In delirium tremens the main elements of prognosis are the occurrence or non-occurrence of sleep before the patient is very much exhausted, the condition of the pulse as tested by the sphygmograph, and the degree of success which attends the physician’s efforts to get nourishment into the system. Sleep, as already remarked, is not of itself curative. The disease, in proportion to its original virulence, has a course of longer or shorter duration to run: this depends in great measure on the quantity of the poison taken, the sufficiency of the eliminative processes, the original strength of the constitution, and the degree in which it can be supported by well-assimilated food. Thus the prognosis is bad in the extreme when the dose of the poison has been very large, the patient’s constitution feeble, his powers of assimilation weak, and, in addition to this, disease of the eliminative organs (especially of the kidneys) exists. Such a case is well-nigh hopeless. Almost equally bad is that in which any severe degree of pneumonia complicates the malady. The test, however, of the patient’s chances, which more than any other I am inclined to value, is the indications given by Marey’s sphygmograph. In proportion as the pulse shows a tendency towards the normal form indicated by this tracing

![Pulse Trace](image1)

are the chances good. On the contrary, such a pulse as the following

![Pulse Trace](image2)

offers the extreme type of that typhoid form which is of most evil augury. This latter tracing was taken from a man, aged 40, who, after remaining for nearly a week in the delirious stage, fell into a sound sleep, which lasted for six or seven hours, and awoke apparently so much improved as to his nervous symptoms, that a somewhat confident opinion was pronounced in favour of his recovery. I augured the worst from the pulse-tracing; and in fact the patient sank rapidly,
about twenty-four hours later. A somewhat extensive experience of
this means of prognosis enables me to recommend it with much con-

cidence. Mere rapidity of pulse counts as nothing in gravity, in my
opinion, in comparison with the obstinate maintenance of the typhoid
form of pulse-wave.

It is almost needless to remark that the circumstance of an attack
being the first of the kind which the patient has suffered, renders it
much less dangerous to life, as a general rule, than a second, a third,
or a fourth would be; but there are important exceptions and quali-
cations to this law. Thus it may happen that a first attack of delirium
tremens seizes a patient who has passed the line of middle age, and
whose nervous system has been already much enfeebled by chronic
disease or bad feeding, but who has never till recently indulged to ex-
cess in drink. Such an individual runs a great danger of sinking under
the first acute attack; and the reason of this may be partly found in
the feebleness of his system, and partly in the circumstance that his
eliminating organs, especially his kidneys, have not become habituated
to the duty suddenly thrown upon them of excreting large quantities
of unchanged alcohol. The same embarrassment of eliminating organs
suddenly charged with an unusual duty is doubtless the cause that a
young man's first debauch (such as that of a young sailor, e.g. put on
shore after his first voyage) so often causes an attack of delirium
tremens; but here the constitutional strength usually enables the
patient to bear up till the natural process of cure has time to be
accomplished.

The prognosis both of acute mania and of acute melancholia from
drink is decidedly good, at any rate on the occasion of first attacks,
and provided that the affection is promptly treated. The probability
of the case passing into one of confirmed insanity, is of course pro-
gressively increased on the occasion of each successive acute attack.

The prognosis of inomamia is in one way very hopeful, in another
almost entirely hopeless. The attacks of the acute affection may recur
any number of times without any serious result: the patient, after a
variable number of hours, days, or weeks, returns to his sober senses,
and resumes his usual course of life. The hopelessness of the case lies
in the taint of insanity, which almost always lies at the founda-
tion of the complaint, and which makes it almost impossible that
the patient can effect a thorough reformation of his habits. However
virtuous his intentions may be, and however strongly he may be urged
by every consideration of prudence, or affection for those whose interests
may depend upon his conduct, it appears as if he were impelled by a
really irresistible force to yield himself, at certain intervals, to the
temptation of drink. When the outbreaks become, as they usually do
in the end, greatly more numerous than at first, there is reason to
apprehend the speedy superintention of confirmed insanity.

COMPLICATIONS.—Of the complications of chronic Alcoholism it
would be impossible to speak in detail, on account of their great
number and variety. The only point to which I think it necessary to direct attention, is the question of the comparative liability of drinkers and of sober persons to phthisis. It appears certain, from the most careful statistics, and especially from those recently collected by Dr. Sutton, that the liability of drinkers to the ordinary forms of phthisis is considerably less than that of temperate people. On the other hand, every physician has now and then observed cases, which may be classed as "galloping consumption," which have occurred in persons who have been leading drunken lives, and which arrive with great rapidity at a fatal termination. I believe these victims of acute phthisis from drink are always descended of tuberculous families; and I think it likely that the starting point of the actual tubercular deposit is to be found in continuous paralysis or semi-paralysis of the "nutritive" fibres contained in the pulmonary branches of the pneumogastric nerve, which is kept up by the patient's drinking habits.

Of acute Alcoholism, the only complication of which I shall separately speak is that of pneumonia. Nothing is more insidious than the occurrence of pneumonia in a subject whose nervous system is deeply poisoned with alcohol. A crucial instance of this occurred in the person of a patient who died in King's College Hospital many years ago without its being suspected that anything more than delirium tremens was amiss, but whose right lung proved, on post-mortem examination, to be hepatised from apex to base. In this case there was no cough, no expectoration, no pain in the chest, and only so much frequency of breathing as seemed sufficiently accounted for by the restless muscular movements of the patient. It is most important, in every case of delirium tremens, that the chest should be periodically examined with care.

PATHOLOGY.—The pathology of Alcoholism naturally divides itself into three portions. The morbid influence which the poison exerts is of three kinds: in the first place, it acts as a local irritant (when highly concentrated) upon the mucous membrane of the stomach and the alimentary canal generally; and in the second place, after absorption, it affects the rate of movement and the vitality of the blood, and as a consequence of this impairs the nutrition of every organ of the body. And thirdly, it is clear that the nervous centres, independently of the ill effects on their nutrition of the blood-changes, have a certain chemical attraction for alcohol, which accordingly is found to accumulate in their tissues.

In the alimentary canal, and particularly in the stomach, the local effects of habitual large doses of concentrated alcohol are seen in permanent congestion of the blood-vessels, exaggerated or vitiated secretions from the gastric glands, and ultimately a degenerative change in the structure of the submucous tissues, which consists in the disappearance of characteristic secreting structures, and the hypertrophic exaggeration of fibrous tissue. Absorbed into the blood in large proportions, alcohol increases largely the amount of fatty matters in
that fluid, and promotes congestion of certain important organs. The congestion of the lungs, liver, kidneys, &c. seems to be partly due to altered chemical relations between the blood and the tissues of those organs, and partly to a paralytic action of the alcohol upon the vaso-motor nervous system. It is by this latter action that I am inclined to account for the abnormal production of sugar in the liver, which has been experimentally observed by Bernard and Harley to follow the introduction of concentrated alcohol into the portal vein, and also for a largely increased excretion of water from the kidneys, which is one of the most invariable consequences of large doses of alcoholic liquors. It is indeed doubtful whether the degenerative changes which result from prolonged alcoholic poisoning are not in great part due to the direct chemical influence of alcohol upon the nervous tissues. The characteristic changes which have been observed in the brain, medulla oblongata, &c. of confirmed drinkers, consist essentially of a peculiar atrophic modification, by which the true elements of nervous tissue are partially removed, the total mass of nervous matter wastes, serous fluid is effused into the ventricles and the arachnoid, while simultaneously there is a marked development of fibrous tissue, granular fat, and other elements which belong to a low order of vitalised products. Essentially similar changes are observed in the lungs, the liver, the kidneys, the heart, and the larger arteries, which (after the nervous centres) are the most frequently affected. The cranial bones are also thickened by a deposit which is not of the nature of a true hypertrophy, for the bones lose much of their original texture, and become dense, almost porcellanous. There is much in these changes which reminds us forcibly of the effects on nutrition of tissues produced experimentally by Schiff and Mantegazza, by the section of compound nerves, such as the fifth cranial, and the sciatic and crural of the lower limb; and suggests the idea that in alcoholic poisoning the starting point (or at least one starting point) of degenerative tissue-changes may consist in paralysis of those nervous branches which preside specially over nutrition, the distinct character of which has been so well pointed out by Brown-Séquard.*

It is highly probable, however, that a considerable portion of the degenerative influence of the continued excessive ingestion of alcohol, is due to a chemical interference with the natural course of oxidation of the blood and tissues. Notwithstanding all that has been urged in favour of the view that alcohol is not transformed within the body, the balance of evidence is strongly in favour of the belief that a considerable portion of every dose of alcohol which is ingested, does undergo oxidation in the system, and that to the diversion from its ordinary purposes of the inspired oxygen must be ascribed the diminished activity of elimination of carbonic acid, of urea, of chlorine, and of the acids and bases of the urine, which undoubtedly does occur in the subjects of alcoholic poisoning.

* Véde Lanceraux, Archives Gén., Oct. 1865, for a full account of the Morbid Anatomy of Alcoholism.
TREATMENT.—1. The treatment of the chronic form of Alcoholism varies according to the stage of the disease which has been reached. In that large majority of the cases which come under our notice, in which the patient merely complains of nervousness, of inability to sleep, of muscular tremor, and perhaps of the slighter forms of visual hallucination, together with some dyspepsia and with morning vomiting, the treatment required is extremely simple. One has only to insure that the patient practises a proper abstinence from drink—to insist upon his taking a diet as rich in nitrogenous matters as may be, but at the same time such as his digestive system can appropriate—and to administer certain tonic medicines; and in nearly every case we may count upon a rapid disappearance of the unpleasant symptoms of which he has complained. With regard to the first item, the prescription of abstinence from drink, a good deal of difficulty may arise, and there is room for difference of opinion as to the expedient course. I wish to express the decided opinion that complete abstinence may always be carried out without any immediate danger to life or health, if proper care be taken to substitute a substantially nourishing diet. The danger of pursuing this course is not a physical but a moral one: all kinds of pledges which, as it were, bind the individual, have a tendency to lessen the force of such notions of personal responsibility as he may retain; he is apt to rest his confidence on the oath or formal resolution which he has taken, instead of teaching himself the virtue of self-restraint, as he would have to do if he were to accustom himself to the moderate use of alcoholic liquors. This is a question, however, which must be left to the practitioner's judgment in each case. The administration of a highly animalised diet is often a matter of difficulty at first, owing to the feebleness of the digestive powers, which renders the use of solid meat impossible, and even that of soups very difficult. Under these circumstances the greatest possible benefit may be derived from the administration from some of the better so-called "concentrated" preparations of meat, more especially Gillon's beef-juice, and a solid extract from this which is prepared by Messrs. Bell, of Oxford Street, as also the better specimens of the extractum carnis of Liebig. Without entering into the vexed question of the exact nutritive value of these preparations, there can be no doubt that they are powerfully reviving to an exhausted nervous system, and that simultaneously with the general improvement which they produce, the digestive organs become strengthened to deal with more bulky forms of animal food. The direct medicinal treatment of chronic Alcoholism in its milder forms is very simple. The presence of dyspeptic symptoms, unless they are very aggravated, and there is reason to believe that serious organic changes in the abdominal viscera have taken place, ought not to distract our attention from the main object of fortifying the nervous system; for with the observance of a proper abstinence from their exciting cause they will rapidly subside. The nervous tonic in which, after a great many trials of different remedies, I have come to repose the greatest confidence, is
ALCOHOLISM.

Quinine in one-grain doses two or three times a day. It should be given from the very first, if possible; and this may be done, even where the stomach is very irritable, by administering the remedy in effervescence, with bicarbonate of potash and citric acid. The symptoms which most of all distress the patient, in the majority of cases, are the persistent wakefulness and the tendency to visual hallucinations or to appearances of black specks, flashes of fire, &c. before the eyes: the insomnia is also, of course, a great obstacle to that repair of the nervous energy without which recovery is impossible. But it would be a mistake to suppose that soporific narcotics, in doses which in a comparatively healthy patient would produce a stupifying effect, are well adapted to relieve this wakefulness: on the contrary, they generally aggravate the nocturnal restlessness, besides seriously impairing the general health. Nothing has been more marked, in my experience, than the superior efficacy of direct tonics, and especially of quinine, in producing that nervous tranquillity which makes sleep possible. Where these medicines prove insufficient, I have found a remedy, which has been recommended by several authors, very useful—namely, sulphuric ether, either given in half-drachm doses three times a day, or a single dose of one drachm at bedtime. A good addition to such a night-draught is half a drachm of the tincture of sumbul.

Another remedy, which has proved very successful in the hands of my friend and late colleague, Dr. Marcet, is the oxide of zinc, which, according to the latter author, has a powerful effect in inducing sleep. He recommends it to be used at first in doses of two grains twice daily, but this quantity may be progressively increased, if necessary, until ten, twenty, thirty grains daily, or even larger quantities, are taken. I have given this medicine very patient trials, both in the smaller and in the larger doses, but I cannot say that I have been so favourably impressed by its action; and on the whole I am inclined to think that in the majority of cases quinine acts much more satisfactorily. It must also be borne in mind, as Dr. Marcet himself admits, that in certain subjects, especially the anaemic and the chlorotic, the continued administration of zinc is observed to produce a prejudicially depressing effect on the constitution. Nevertheless there is no doubt that oxide of zinc occasionally proves a valuable remedy. I think it should not be administered in larger quantities than at most six grains daily; and I concur with Dr. Marcet in the recommendation that it should be given shortly after a meal, as it otherwise sometimes occasions nausea.

A much more effective remedy than zinc appears to be the bromide of potassium in ten or twenty grain doses three times a day. Although I have not yet had the opportunity of trying this medicine so extensively as I should wish, the results obtained have been very good. In several instances it has at once removed distressing wakefulness, dreams, and visual hallucinations. It is occasionally impossible to give this drug, however, from its exciting gastric irritation.

Now and then we find that sleep is not to be obtained by any of
the remedies above mentioned, and we are driven to the use of some of the more recognised hypnotics. Of these one of the most effectual is the extract of Indian hemp; it should be given in small doses; from a quarter to half a grain of a good extract is quite sufficient, and a larger quantity is more likely to do harm than good to the majority of patients. Opium, if given at all, should be administered in the form of morphia, hypodermically injected; one tenth to one quarter of a grain is sufficient. But a medicine which is quite as effectual in many cases is good bottled stout given in one single dose of half a pint at bed-time.

In the more advanced cases of chronic Alcoholism, where the nervous centres are undergoing serious degenerative changes, as evidenced by the occurrence of paralysis, epileptiform convulsions, or grave mental deterioration, further remedial measures are required. Of these the two which have yielded me by far the most satisfactory results are cod-liver oil, and phosphorus in the form of the hypophosphites of soda or lime. Cod-liver oil, to be really of use, must be continued in tolerably full doses over a long period. Employed for so long a time as three or six months without intermission, I have seen it produce striking benefit even in advanced stages; and in some instances where it failed to produce anything like a cure, it caused great amendment of the most serious symptoms. The hypophosphites in five and ten grain doses, three times a day, have been particularly valuable, in my hands, in the treatment of cases which were distinguished by commencing paralysis of sensation. In one case which was marked by epileptic convulsions, with much impairment of the mental faculties, the combined use of cod-liver oil and bromide of potassium produced very beneficial effects. Another class of cases, those in which the predominant symptom is a very considerable degree of muscular tremor, are often greatly benefited by strychnia. Very small doses, only, are to be used; it is well to commence with the $\frac{1}{20}$th of a grain, and increase this to not more than the $\frac{3}{4}$d of a grain, three times daily. Doses much larger than this have invariably seemed to do decided harm, especially increasing the tendency to vertigo, visual hallucinations, and noises in the ears.

2. The treatment of acute Alcoholism. (a) Delirium tremens is a malady the treatment of which has experienced several changes correspondingly with the progress of accurate clinical observation. In former times—indeed a very few years since—the notion universally prevailed that the delirious symptoms were owing to the exhaustion which was chiefly kept up by want of sleep; and consequently, that the production of continuous sleep for several hours was the sole and all-important means of cure. It was therefore the custom to ply the patients with larger and larger successive doses of opium, with a view of drowning the delirium in narcotic stupor. Great mischief arose from this wide-spread belief and practice. In the first place, it has often happened that the patient, without ever sleeping at all, has passed first into a condition of coma-vigil, next of stertorous breathing,
and at last sunk, fairly poisoned with opium. Again, a fact which was disregarded by the earlier authorities was this, that, without exerting any poisonous action upon the centres of consciousness, opium occasion-
ally spends almost the whole of its depressing force upon the visceral
nerves. A minor consequence of neglecting this fact was, that the pa-

tient’s chance of assimilating food was often entirely ruined by the
paralysing action of the drug upon the digestive organs: a much more
serious one was the accident which has doubtless often happened, and
which occurred in cases within my knowledge—namely, the
rapid induction of a cardiac paralysis, the patient (without any
cerebral signs of poisoning whatever) suddenly becoming ghastly pale,
the pulse fluttering and coming to a stand-still within a few moments.
One such example was particularly striking, as it immediately followed
two large doses of opium, which had been given in the vain hope of
procuring sleep; the second dose was equally inefficacious as a sono-
risf the first, but its deadly effect upon the circulation could
not be mistaken.

The idea that patients in delirium tremens require to be narcotised
into a state of repose, may now be said to be abandoned by those
best qualified to speak on the subject. In truth, the condition of the
brain requires that sort of treatment which shall fortify and stimulate
its functions. I have already argued at length, in another work, that
every stimulant, when given in such restricted doses as alone deserve
that name, is a promoter, but not an exhauster, of function, and that
the idea of any depressive recoil following its action is purely fictitious.
There are, accordingly, a great number of remedies of which the larger
doses are narcotic, and the smaller stimulant, which in the latter form
are capable of giving more or less relief to the symptoms of delirium
tremens. It is not worth while to enumerate all these. The typical
member of the group of stimulants is simple, easily-digested food;
and the successful treatment of delirium tremens, in nine cases out of
ten, depends on the regular and continuous supply of suitable nutri-
ment, whereby the functions of the nervous system are supported
during the struggle towards recovery. The principal kinds of food
which are desirable are milk, soup, or strong broth with bread in it
(and given very hot), the concentrated meat-foods already recommended
under the head of Chronic Alcoholism, and raw eggs beaten up. The
necessity for the administration of some nutriment of this kind is
imperative; and if the stomach be at first too irritable or the anorexia
too complete to allow of feeding by the stomach, it must be given in
the form of enemata, so as not to lose a day, nor even a few hours.

It should be observed, however, that there are two classes of
patients, in one of whom it is, and in the other it is not, desirable to
employ some preparatory treatment of an eliminative kind. The
value of purgatives has been recognised by many writers. They are
eminently suitable to those cases in which a young and somewhat
robust person has brought on delirium by drinking a very large
quantity of spirits; in such instances a dose or two of medicine,
producing free watery evacuations, effects a wonderful improvement (no doubt by ridding the system of much of the alcohol which it has absorbed). Where the strength of the patient is sufficient to allow of this plan being safely carried out, it will be found that the sub-
sequent assimilation of food is rendered more easy and rapid, and that the stage of convalescence is comparatively soon attained. But in debilitated subjects it is far better not to attempt any forced increase of the eliminative processes, but to commence at once with the administration of the more easily digested foods in small quan-
tities frequently repeated. The irritation of the stomach may be
combated by the administration of ice, and of small quantities of soda-water and other aerated drinks, and one of the best modes of commencing the necessary feeding is by administering milk, mixed with one-third its bulk of lime-water, at frequent intervals. Every-
thing is to be hoped for a patient who has been well supported by food from the early stages of the attack.

Of late years an important question has been raised concerning the therapeutic value of digitalis in delirium tremens. The practice, intro-
duced by Mr. Jones of Jersey, of administering very large doses of tinc-
ture of digitalis (from half an ounce to an ounce, and even more), was a startling innovation on the traditional practice in the use of this drug; such doses having formerly been universally regarded as dangerously poisonous, and calculated to produce fatal depression of the circula-
tion. It has been proved, beyond doubt, that in a large number of cases these doses are at least harmless, and the testimony of a good many observers has now apparently established the fact that the delirium may frequently be quieted, and sleep obtained by the em-
ployment of digitalis in this manner. It must be owned, however,
that the question still remains in a very unsatisfactory position. The great majority of the cases have been treated with the tincture, and not with any simple preparation of digitalis: that is to say, the patients have, in fact, received half-ounce or ounce doses of proof spirit over and above the drug intended to act upon the disease. But it is well known that alcohol, in common with all the stimulant class of remedies, has often a beneficial influence in states of low delirium. In the presence of the very conflicting statements on the action of digitalis which have been published by different writers, I have endeavoured to clear the matter up by employing a strong infusion instead of the tincture; but it is unfortunately impossible, in many cases, to get the patients to take the remedy in this shape, and I have thus been hindered from effectively carrying out the experi-
ment. The powder, given in pills, would be a better form. From the observation of a few cases, treated with digitalis in one form or another, which have been under my own treatment or that of friends, I have been led to the provisional conclusion, that in all probability a large number of the reported successful cases have either been instances of a spontaneous favourable termination of the disease, or have been slightly helped towards their happy issue by the alcohol
which is contained in the tincture ordinarily employed. This consideration leads us naturally to consider the very important question—whether alcoholic liquors should or should not be used in the treatment of delirium tremens.

I am inclined to think that the moral argument has great weight here. In all cases, and more especially in first attacks, the subjects of which, we may hope, are not irremediably debased by drunken habits, it appears to be incumbent on us to use the time of sickness as an opportunity for possible reformation unless alcohol were necessary. It would, therefore, seem to be our duty to commence the work by giving the patient’s system an entire rest from the action of alcohol during the period for which he is under our authoritative guidance. In young subjects, therefore, and in first attacks, it is proper to abstain altogether from the use of alcohol. It is more difficult to carry out this plan with older patients, and with those who have been for a long time accustomed to depend upon strong drinks for a large part of their ordinary nutrition. In every case, however, I think it is our duty to abstain as long as possible from the use of alcohol, and before resorting to a treatment of such doubtful propriety we ought to try less harmful narcotic stimulants. Opium and Indian hemp fulfil the indications which we require, under these circumstances, better than any others of their class. Opium should never be administered by the stomach, but always in the form of morphia hypodermically injected, in the dose of one-tenth to one-fourth or one-half grain. Where there is any reason, from the quality of the pulse, to believe that the circulation is much enfeebled, Indian hemp, in doses of a quarter to half a grain of a good extract, is a less objectionable remedy, and I have seen it produce excellent effects.

A very important question is the propriety or otherwise of employing the inhalation of chloroform, in order to quiet the patient sufficiently to enable him to sleep: on this matter there has been the greatest difference of opinion. My own experience of this remedy may be summed up as follows:—In the first place, I have known from personal friends of two cases (and many others have been recorded) in which the patient died suddenly, from cardiac palsy, while the inhalation was proceeding. Secondly, I do not believe, though I have frequently tried it, that the action of small doses of a weak atmosphere of chloroform (such as would be free from the danger of producing cardiac palsy) is sufficient to induce sleep, or even to greatly reduce the patient’s agitation, in the majority of cases. And lastly, remembering how few persons possess a high degree of skill in exactly graduating the dose of chloroform-vapour, it appears undesirable that it should come into general use in delirium tremens. For it is certain that the evil effects of a narcotic depression of the heart’s action are much more serious in the case of this disease than of many other complaints. Given internally, in doses of twenty to thirty minims (or an equivalent amount of chloric ether), chloroform is less dangerous; but, as far as my experience goes, not more successful. Other practitioners, how-
ever, have met with more success in its use, and some have pushed it
to much larger doses; but considering that forty-five minims taken
internally by a healthy man has been known to produce full anaesthesia
(though this is usually too little to produce such an effect), it is not
advisable to run the risk of larger doses than I have named.

In all probability another remedy, which has only lately become the
subject of attention in respect to delirium tremens, will prove the best
of all the auxiliary means for quieting nervous agitation and hastening
the advent of convalescence. I refer to the bromide of potassium.
As yet I have not had the opportunity of fairly trying this drug; but
it has yielded in the hands of several practitioners the most beneficial
results, when given in twenty-grain doses, repeated at intervals of a
few hours till sleep occurs.

A remedy which has been used with great success in many cases,
and with most unfortunate results in others, is tartar emetic. The
handling of this drug in delirium tremens is an extremely difficult
thing, for it requires much judgment to decide whether the constitu-
tional strength of the patient is sufficient to support its undoubtedly
depressing effects. I venture to believe that the directions, so often
given, to employ antimony in cases which are distinguished by
"active" delirium, with a bold and threatening (instead of a timid) ex-
pression of countenance, congested conjunctive, &c. are quite worthless.
Such symptoms afford no measure of the patient's real strength, nor
are they any warrant for the use of antimony; for this remedy must
be given in considerable doses, if it is to do any real good: from the
quarter to half of a grain should be given three or four times, at in-
tervals of one or two hours. When a favourable effect is produced, it
is always accompanied (and I believe caused) by an increased secretion
from the kidneys, or by profuse sweating, by which probably the
elimination of alcohol is favoured. Scantiness of either or both these
secretions is therefore the true indication for antimony. But it is
necessary, even when these indications exist, to form a very accurate
judgment of the strength of the circulation, and this, if we trust to
the finger's estimate of the radial pulse, is most difficult. Fortunately
the use of Marey's sphygmograph will enable us to form a far more
correct opinion than was formerly possible on this point. The symp-
toms which indicate a dangerous action of tartar emetic are faintness,
cold sweating, and intermittence or irregularity of the pulse: the latter
symptom should be carefully looked for with the help of the sphyg-
mograph, which may detect it when the finger could not. If the first
dose produces even a slight irregularity of cardiac rhythm, the
medicine should be at once suspended.

The treatment of the complications of delirium tremens hardly
requires any special remarks, except perhaps as to the complication
of pneumonia. It is, of course, necessary, as a general rule, to be
specially careful to avoid unnecessarily depressing treatment of
affections the original cause of which is the action of a depressing
narcotic poison such as alcohol: but this rule is of twofold importance
in the case of pneumonia supervening in acute Alcoholism. I am satisfied that I have seen the life of a patient sacrificed by the administration of two or three consecutive quarter grain doses of tartar emetic, under the idea that this treatment was specifically indicated by the affection of the lung. Tartar emetic, blood-letting both general and local, purgatives, and every other depressing treatment are to be utterly proscribed in alcoholic pneumonia, an affection which is attended with much greater debility, especially of the heart, than its superficial symptoms would appear to indicate. The sphygmonograph is very useful as a test of the real condition of things.

One important branch of the treatment remains to be briefly noticed. It is in all cases most highly desirable that a skilled attendant should be procured, and in cases where the patient is at once violent and of considerable strength, two trained persons, with experience of the treatment of lunatics, should be placed in constant attendance. It is scarcely necessary to say that the utmost violence of a patient should never induce us to employ bandages or the strait-waistcoat, if it be anyhow possible to secure sufficient nursing assistance.

(b) The treatment of acute mania from drink is a subject which belongs properly to the department of mental diseases, and

(c) The treatment of alcoholic melancholia is in the same position, as is also

(d) The treatment of oinomania.

In order to give as much continuity as possible to my description of the diseases grouped under the term “Alcoholism,” I have purposely avoided long digressions upon the views held by other writers, and have made comparatively few quotations of their writings. But in order that the reader may have an opportunity of comparing this article with the teachings of other modern writers, I subjoin the following list of the principal works which are now looked upon as possessing authority on this subject:—

A SYSTEM OF MEDICINE.

ECSTASY.

By Thomas King Chambers, M.D. F.R.C.P.

By intense concentration on one object, engaging only a few of the intellectual faculties, the mind is liable to lose temporarily its sensitive and controlling power in respect to its other relations. In minor degrees this state is a matter of daily experience with us all, and in minds of average strength it does not seem to go beyond minor degrees. They do not wish or practise such intense concentration; they are able to do and feel all they want to do and feel without over-tasking themselves. But there are some, either naturally weaker, and so incapable of full feeling without concentration, or else desirous of a higher degree of emotion than they are healthily capable of; and in these a condition may be adduced allied in some respects to catalepsy, and in some to hysteria—a condition certainly morbid, for it renders the patient unequal to the functions of social life, and is excited by causes which affect some and not others.

Sometimes the patient falls into a state of immobility, in which there is a passive reception of ideas, like that of the Midianite prophet “falling into a trance, but having his eyes open,” a state he evidently considered rarer than that of a mere dreamer of dreams. Hoffman* describes an ignorant peasant woman of twenty-four, after a fortnight’s course of exciting sermons, remaining motionless for more than an hour; after which she gave a few sighs and returned to herself, having seen or heard nothing of what was going on about her, but having had exquisite revelations of the love of Christ. During forty days she had a hundred returns of the same state, which would always be induced by a recitation of a few verses of the Scriptures concerning the love of God. During the fits the pulse remained quite natural. They were finally removed by a change of air and scene, after bleeding and stimulants had failed. The followers of St. Francis, in the days of faith, were often brought into these ecstasies by fasting, meditation, and abstinence from varied intellectual exertion. Nowhere is it so strikingly depicted as by the Tuscan artist Cigoli, a man of by no means lively fancy, for, except an Ecce Homo, he painted nothing well but ecstatic and starving Franciscans. So he is probably truthful. After visiting each Florentine gallery it is difficult to expel from one’s memory these strange figures, of marble paleness, kneeling, but sunk

* Medicina Rationalis, vol. iii. p. 50.
on one side from exhaustion, the eyes open, the pupils fixed, the arms extended to embrace the beloved vision, the livid lips parted in smiles, showing the parched dark mouth, the breast heaving with delight. It is necessary to add only one medical fact, derived from M. Sagar’s observation* of a Capuchin in this state; namely, that the pulse was pretty strong.

One main psychical difference between this and catalepsy lies in the visions which are recollected afterwards with all the force of reality. In true catalepsy all memory of what is done during the fits is completely wiped away—a phenomenon which may assist in the detection of impostors.

A more common development of Ecstasy is where the sufferer feels “borne in upon him,” a desire to communicate to others the feelings he is sensible of himself, instead of reserving the experience till afterwards. The simplest instances of this are the scenes which take place from time to time in the Primitive Methodists’ or “Ranters”’ chapels. The congregation groan and respond to the feelings of the preacher, second his words with their own experience, and various members work themselves up into a state of excitement, repeating the last words of the sentence, “Salvation! salvation!” or whatever else it may be, with continually increasing earnestness, till they end in shouting and sobbing.

The next stage or form of Ecstasy is where the enthusiasm tries to express and exhaust itself in bodily movements. One of the most famous instances of this is the spasm of the Convulsionnaires de Saint Medard, a disease which was by neglect allowed to attain most formidable proportions in the last century. Strangely enough it arose out of the dreariest of dogmas; namely, those which were in dispute between the Gallicans and Ultramontanists on the occasion of the bull “Unigenitus.” A famous Gallican deacon, named Paris, died in 1727, and was buried at St. Medard; and on his grave people began to fall into convulsions, be affected with clairvoyance, preach, jump, spin round with incredible rapidity, run their heads against walls, &c. &c. Of no avail was Louis the Fifteenth’s proclamation, which some one parodied,

"De part le Roi! Défense à Dieu
De faire miracles dans ce lieu."

In spite of it Convulsionism grew into a sect, and was at last only smothered by the French Revolution.

A transition between this form and the last is exhibited in Revi- valism; and its reduction to a certain system and order is shown in the ceremonies of the Jumpers of New York and the Dancing Dervishes of Cairo.

Sporadic cases of this ecstasy not infrequently occur in the experience of the promulgators of new or arousing doctrine; but judicious discouragement has usually prevented its becoming historical. We meet with it in the biographies of such men as Samuel Wesley and

Edward Irving; and a valuable lesson is to be learnt from their wise mode of dealing with it, especially the former.

The mention made of this disease being used by dishonest or foolish people as a bond of union for religious sects, leads to a point in its history which constitutes the main interest it possesses for practical consideration. It is eminently communicable, especially in its more active, noisy, and ridiculous forms.

There is not much worth reading in the Pastoralis of Longus; but one expression of his—"τῶν ὀφθαλμῶν ἀλωσίως, " the contagion of the eyes,"—is so picturesque and truthful that he deserves the credit of it. Through the eye instinctive imitation, or sympathy, directs the first intellectual and corporeal efforts of the infant, and makes him grow up in the image of his kind; and, as Longus felt, it is by such means that two adult souls get bound into one. So also through the eye flashes in that morbid state in which a nervous malady fetters the normal powers of control, binding them up as with an electric spasm, and allowing the lowest animal emotions to exhibit themselves. An initiative compliance, a voluntary surrender of the gates of the soul, is doubtless necessary at first; but with each yielding the energy is weaker, and this natural and healthy sympathy may pass into an actual disease of the mind, in which the power of the will is quite in abeyance.

In this way, from the accidental eccentricity, convulsion, or insanity of often a single person, the strange spasmodic epidemics of the Middle Ages arose. We can easily understand the disorganization which they produced among the lower orders, when we read that a few months after a new appearance of the "dancing mania" at Aix-la-Chapelle, on St. John's Day, 1374, there were as many as eleven thousand dancers in the streets of Metz. In this instance, at least, the outbreak took its rise in the scandalous midsummer revels, which had been handed over from paganism to the ascetic Baptist's festival, in spite of the protests of the Church from St. Augustine to Pope Boniface. The origin was a disreputable one, so the dancers hastened to avoid the inference by placing themselves under the protection of St. Vitus, one of the fourteen "Helpers in need."* For full 150 years it was in Germany a most serious plague, of which a full history is given in Hecker's Epidemics of the Middle Ages. As a translation of that graphic description is published by the Sydenham Society, it is unnecessary to do more than refer to it those who are anxious to trace to its most disgusting results an extreme indulgence in uncontrolled sympathy.

Spasmodic epidemics seem to have appeared in Italy about the same time as in Germany, but to have been for some time confined to Apulia. At the end of the fifteenth century they spread further, and coincident with there seems to have been observed an increase in the

* Most travellers in Flanders and Germany are probably familiar with the shrines of the fourteen "Notthelfer" or "Apotheker" saints, spiritual specialists, of whom one cures toothache, another stone, another cancer. It is a curious fact that the regularly educated physicians, St. Luke, St. Cosmo, and St. Damian, are not among them.
numbers of the tarantula or ground-spider. The two facts became associated together, and a panic flashed like lightning through the country that this creature was communicating the disease by its bite. Of "tarantism" in Italy, pure fright was as potent an exciting cause as superstitious fanaticism had been of the "St. John's" or "St. Vitus' dance" in Germany. And for this reason it affected a higher and better educated class of society. Even a sceptical prelate did not find his free-thinking a protection. Quinzato, Bishop of Foligno, having allowed himself in joke to be bitten by a tarantula, fell into the disease, and could only be cured in the undignified method adopted by vulgar laymen. (Hecker.) He was obliged to kick off his shoes (such at least is the necessary prelude now-a-days) and dance the tarantella.

As an epidemic, tarantism has long disappeared, but sporadic cases are said still to occur, and hysterical women will persuade their gossips that they have been bitten by the tarantula, and that they cannot get rid of their mental fidgets without an immoderate indulgence in the traditional cure by dancing.

Of the exciting causes of Ecstasy, and its allied spasmodic epidemics, perverted religious feeling seems the most common. And this for the simple reason that, since the diffusion of Christianity, religion has a more powerful hold upon the emotions than anything else. But all historians agree in attributing much influence also to venereal excitement; and in pre-Christian times, when in default of revelation men worshipped their incarnate passions, we have from the pen of Sappho a description of a purely erotic ecstasy, which can never be paralleled again. And in the case of tarantism it seems to have been cowardice which was the exciting cause.

The history of the treatment of exaggerated instances of this disease is instructive to us, not from the likelihood that any of this volume's readers will be called upon to undertake it, but as a suggestive guide for the management of allied, semi-mental, semi-corporeal states, which are as commonly, as it is rarely, under medical charge. Allusion is especially intended to two—chorea, the heir to the name, and in a diluted degree to the nature, of the mediaeval mad dancers who put themselves under the protection of St. Vitus; and to hysteria, which, being more usual among women than among men, has acquired a name derived from a part of their bodies anciently supposed to produce the symptoms—a nomenclature often leading to bad practice.

1. If taken in time, ecstatic and emotional exhibitions are capable of being forcibly repressed. For example, in Unst, the most northerly of the Shetlands, an epidemic of convulsive fits occurring in sermon time began to prevail in several parish churches. At one of these, Northmaven, the disease was cut short by a rough fellow of a kirk officer, who carried out a troublesome patient and tossed her into a wet ditch. Nobody else caught it.* From what scandalous scenes Europe might have been saved had the first dancers on St. John's eve been tossed into a wet ditch!

2. A strict quarantine prevents infection. In 1796 an epidemic convulsion spread to twenty-four persons in Anglesea. Their landlord, Lord Uxbridge, consulted Dr. Haygarth, and by his advice all communication with the afflicted persons was prevented, and the plague was stayed, as he records.*

I have often had chorea and hysteria arrested in hospital wards on separating the patients thus diseased, who had been keeping up one another's malady by sympathy.

3. Order, rhythm, designed consecutiveness, and in short anything implying voluntary control, has a beneficial effect in this class of complaints. Doubtless when once Sappho had grown particular in winding up with a dactyle and spondee the pretty stanzas named after her, when Madame Guyon had learnt to be careful of her rhymes, and Saint Theresa had committed her devotions to paper, all danger of contagious enthusiasm was past. But it is only an intellect of above the average capacity that can undertake to reduce itself to order in this way. Those afflicted in Germany with the epidemic convulsions lately alluded to, took to dancing, evidently with an instinctive feeling that rhythmical movement was a relief to their morbid sensations; but in that country the application of it as a mode of cure does not appear to have been turned to such good account by art as in Italy. The tarantellas I have seen performed in South Italy are very complicated figures, accompanied by an amount of arm-waving, finger-snapping, simultaneous wriggling, slapping of hands, bumping of backs, and crossing one another's footsteps, that can only be accomplished by a strict adherence to time. And the time is marked by a tambourine or drum. These dances are probably much older than tarantism; but for the cure of it they became popular, and from it they got their name. It is impossible to doubt that they had a real influence, even over those who undertook them unwillingly, as in the case of the sceptical bishop lately alluded to. The peculiar features of them, to which I should attribute their usefulness, are the marked time and intricate figure, by which they are honourably distinguished from the senseless rotatory embrace now called dancing.

I am sure I have seen decided benefit in hysteria from dancing reels, and there would probably be much more, if time were better marked and kept.

In chorea, marching in timed step is excellent practice for regaining the directing power over the limbs. In stuttering, which is a sort of chorea, spouting poetry before a looking-glass contributes much to the cure.

NAME.—This word Catalepsy is derived from the Greek κατάληψις, a "seizure" or "arrest."

DEFINITION.—Catalepsy is the name given to intermittent attacks of a suspension more or less complete of sensation and voluntary power, without convulsions, accompanied by a stiffening, general or partial, of the muscular system; so that the parts affected retain for a period of variable duration the position in which they happen to be at the invasion of the fit.

DESCRIPTION.—This is one of those pathological phenomena of whose anatomical cause we are entirely ignorant, and therefore it is best defined by its symptoms, instead of committing ourselves to any vague theory of its nature. It is best to call "Catalepsy" any attack which fulfils the conditions above named, and then we shall at once avoid all those discussions with which writings on the subject are laden about "true" Catalepsy and "false" Catalepsy, and the separation into symptomatic and idiopathic, which we have no warrant for making at all. It is as much Catalepsy, and the ultimate morbid state is essentially the same, whether it is followed by a disease with another name, or whether it is followed by restored health.

The following account of a well-marked case by Dr. John Jebb describes the details of Catalepsy more graphically and fully than any I have yet read. He says:*

"In the latter end of last year (viz. 1781), I was desired to visit a young lady who for nine months had been afflicted with that singular disorder termed a Catalepsy. Although she was prepared for my visit, she was seized with the disorder as soon as my arrival was announced. She was employed in netting, and was passing the needle through the mesh, in which position she immediately became rigid, exhibiting in a very pleasing form a figure of death-like sleep, beyond the power of art to imitate, or the imagination to conceive. Her forehead was serene, her features perfectly composed. The paleness of her colour, her breathing at a distance being also scarce

perceptible, operated in rendering the similitude to marble more exact and striking. The positions of her fingers, hands, and arms, were altered with difficulty, but they preserved every form of flexure they acquired: nor were the muscles of the neck exempted from this law, her head maintaining every situation in which the hand could place it as firmly as her limbs.

"Upon gently raising the eyelids, they immediately closed, with a degree of spasm. The iris contracted upon the approach of a candle, as if in a state of vigilance; the eyeball itself was slightly agitated with a tremulous motion, not discernible when the eyelid had descended.

"About half an hour after my arrival, the rigidity in her limbs and statue-like appearance being yet unaltered, she sung three plaintive songs, in a tone of voice so elegantly expressive, and with such affecting modulation, as evidently pointed out how much the most powerful passion of the mind was concerned in the production of her disorder, as indeed her history confirmed. In a few minutes afterwards she sighed deeply, and the spasm in her limbs was immediately relaxed. She complained that she could not open her eyes, her hands grew cold, a general tremor followed; but, in a few seconds, recovering entirely her recollection and powers of motion, she entered into a detail of her symptoms, and a history of her complaints.

"She informed me that she had no recollection whatever of what passed in the fits; that upon coming out of them she felt fatigued, in proportion to the time of their continuance; and that they sometimes lasted for five hours, though generally for a much shorter period.

"She further related, that the fits returned once or twice a day, sometimes more frequently; but that she was never troubled with them in the night. She sometimes lost her sight and speech, the power over her limbs and her intellectual faculties remaining unimpaired. The fits frequently attacked her without any previous warning; at other times, a fluttering at her stomach, and a fixed pain at the top of her head, occupying a part she could cover with her finger, announced their approach.

"Hysterical risings in her throat, appearances of fire, pains in her eyes, and not infrequently in her teeth, flatulence, a sense of weight in her stomach after eating, with convulsive motions in the region of that organ, were superadded symptoms of which she much complained.

"Her disorder was evidently exasperated at the approach of the catamenia, which were constantly present at the regular period. She was always much agitated previously to a storm of thunder, and every material alteration of the weather produced a sensible effect.

"After she had discoursed for some time with apparent calmness, the universal spasm suddenly returned. Her features now assumed a different form, denoting a mind strongly impressed with anxiety and apprehension. At times she uttered short and vehement exclamations, in a piercing tone of voice, expressive of the passions that
agitated her mind, her hands being strongly locked in each other, and all her muscles, those subservient to speech excepted, being affected with the same rigidity as before.

"During the time of my attendance similar appearances were frequently exhibited.

"I was informed by the family of many particularities in the access of the disorder, all denoting its instantaneous effect upon the nervous system. She once was seized in my presence while drinking tea, and became universally rigid at the instant she was advancing the tea-cup to her mouth. Her tears sometimes flowed copiously, while every internal, as well as external, sense seemed entirely locked up in sleep.

"I will now proceed to describe the progress of the disorder, and the mode of treatment, before she was entrusted to my care.

"It appears that for many years before the access of the cataleptical symptoms, she had suffered much from violent headaches, particularly that species of headache termed clavus hysterics. Her spirits were easily discomposed. Her fingers, upon touching cold substances, would frequently lose their natural heat and feeling. Her habit of body had been uncommonly costive, but of late her bowels were much disturbed by every kind of laxative. Her nervous complaints were always particularly troublesome at the approach of rain and after a sleepless night.

"Her disorder commenced with hysteric fits; to these succeeded a delirium of several days' continuance, attended with slight shiverings, but no other sign of fever; the Catalepsy followed next in order, which at first affected her with only single fits, at a week or fortnight's interval; these gradually advanced in strength and frequency until by her own sufferings, and her sensibility on account of the anxiety of her friends, she was reduced to the most pitiable distress."

Then follow details of the treatment advised by Dr. Jebb, which was judicious and successful. An opium plaster to the epigastrium did good, but the last and longest continued prescription consisted of bark, gentian, and tincture of lavender, which she went on with till quite well.

This exceedingly well-drawn-up description makes one regret that the accomplished author had not continued to apply his pen to depicting the eternal truths of nature, instead of wasting it upon theological and political advocacy. It renders needless the repetition of stock cases which usually illustrate the subject.

CAUSES.—The most common exciting cause of Catalepsy seems to be strong mental emotion. When Covent Garden Theatre was last burnt down, the blaze flashed in at the uncurtained windows of St. Mary's Hospital. One of my patients, a girl of twenty, recovering from low fever, was woke up by it, and exclaimed that the day of judgment was come. She remained in an excited state all night, and the next morning grew gradually stiff, like a corpse, whispering (before
she became quite insensible) that she was dead. If her arm was
raised, it remained extended in the position in which it was placed for
several minutes, and then slowly subsided. The inelastic kind of
way in which it retained its position for a time, and then gradually
yielded to the force of gravity, reminded one more of a wax figure than
of the marble, to which Dr. Jebb compares it. A strange effect was
produced by opening the eyelid of one eye; the other eye remained
closed, and the raised lid after a time fell very slowly, like the arm.
A better superficial representation of death it is difficult to conceive.
The pupils, however, contracted sluggishly under the influence of
light; and the pulse could be felt beating softiy at both heart and
wrist. She came round again by degrees in the course of the morning,
and had no relapse; nor had she any manifestations of ordinary
hysteria during her stay in the hospital, I believe.

Less acute, but more long-continued mental emotion will sometimes
cause it. The same year as that in which the last case occurred, I
was attending for menorrhagia from relaxed fibre a young woman,
aged twenty-two or twenty-three, who had been a governess in a family
I was acquainted with. She was of an affectionate disposition, and
had been rather coldly treated,—"misunderstood," as it is called. The
menorrhagia, too, had pulled her down a good deal, and forced her into
involuntary idleness. One morning when I called to see her, she was
in bed, unable to move, and scarcely capable of articulating. She said
she was just recovering consciousness, but all the limbs were partially
stiff, and the neck and back quite so, as appeared by raising her up
with the hand at the back of the neck, when the body remained
straight, resting on the heels. This state soon passed off, even while I
was in the room. But the next morning I found her partially affected
in the same way; the left side was rigid, and especially the left arm,
which remained stretched out at an angle when so placed.* I observed
that when I bent the arm, the deltoid contracted as it does when
flexion is made by voluntary effort. She then told me that, though
quite incapable of moving the limb of her own unassisted will, she
thought she could do so if I bade her very strongly. And such proved
to be the fact; for, on my rating her soundly and ordering her to get
up, she at last obeyed. I explained to her what I believed to be the
nature of the disorder, namely, a broken connexion (to speak meta-
phorically) between the will and the nervous system; and that she
must rejoin this broken link by painful exertion and violent determi-
nation. She had no further relapse.

In both these cases I convinced myself carefully that there was no
deception.

Catalepsy is sometimes very brief and sudden. I have a young
lady now under my care, for non-assimilative indigestion, of whom I
received the following accounts from a mother of more than ordinary
intelligence and powers of observation. She said that her daughter

* M. Tissot mentions a similar case of partial Catalepsy affecting the arms in a man.
(Envres, tom. xiii. p. 56.)
was fond of reading aloud, and that sometimes in the middle of a sentence the voice would suddenly stop, a peculiar stiffness of the whole body would come on and fix the limbs immovably for several minutes. Then it would relax, and the reading would be continued at the very word it stopped at, the patient being quite unconscious that a parenthesis had been snipped out of her existence, or that aught strange had happened. She grew much better under tonic and restorative treatment, and gradually ceased to have these singular attacks; but after about a month's interval, as she was one evening engaged in playing a round game of cards, she suddenly went off into a regular epileptic fit, which was followed by sleep, and she did not recover consciousness till the next morning. This fit could be accounted for by certain errors in digestion, and she has had no recurrence of it, or of the Catalepsy, though four months have passed over. So I hope it was epilepsy of an intercurrent or curable sort.

But sometimes the epilepsy preceded by Catalepsy is of a more serious sort. I remember a much respected lecturer in this metropolis, in whom the petit mal of epilepsy assumed this form. He used to be attacked sometimes in the middle of a sentence, with his hand wielded in demonstration before his class. He would remain perfectly stiff for a minute or so, with mouth open and arm extended, and then resume his sentence just where he had dropped it, quite unconscious that anything had happened. After a time the seizures assumed the more usual and more fatal form.

This sort of short attack is not, however, always the precursor of anything so serious. Nor, if traceable to a material cause, is that cause necessarily in the brain. Van Swieten tells a story of a woman, forty years of age, who was roasting chestnuts in the frying-pan, and kept continually stirring them lest they should be too much scorched; in doing which, she was seized with a true Catalepsy. As Van Swieten lived hard by, he was immediately called in; in his presence she suddenly vomited two live worms, and forthwith proceeded with her cookery, quite unconscious of what had happened. She had no relapse.*

Other cases are of much longer duration. The death-like state may last for days. It may be mistaken for real death, and treated as such. In the old pre-Christian times we do not hear of this, though it was a sort of thing that would appeal strongly to the feelings and memory. No Sadducee seems to have suggested Catalepsy to discredit the real resurrections recorded in the Gospels;† and the fear of being accidentally buried alive is never alluded to by the classic writers, though so picturesque and so capable of poetical treatment. Any cases of

† Had he done so, it would have been a telling argument for the Council and the Scriptures; but it would have small weight with an experienced physician now, nor would it make the miracle any the less in his eyes. He would know that it is quite as supernatural to detect a cataleptic in a funeral-train accidentally met at the city gate, or in one who had lain three days in a tomb completely rolled up in mummy cloth, as it is to raise the dead.
apparent death that did occur were burnt, or buried, or otherwise put out of the way, and were never more heard of. But after the establishment of Christianity, tenderness, sometimes excessive, for the remains of departed friends took the place of the hard heathen selfishness. The dead were kept closer to the congregations of the living, as if to represent in material form the dogma of the communion of saints. This led to the discovery that some persons, indeed some persons of note (amongst others, Duns Scotus the theologian, at Cologne), had got out of their coffins, and died in a vain attempt to open the doors of their vaults.

Others were more fortunate. Those who have visited the Lutheran cathedral at Magdeburg, have probably not failed to notice a quaint monument to the Frau von Asseburg. There is her effigy on it in stone, kneeling with her husband, and, in the style of the period, a goodly line of sons on one side and daughters on the other support the pair. The inscription relates how that this noble lady was, after her marriage, supposed to be dead and placed in the family vault. Luckily the entrance was left unclosed that night, for she rose up, returned to her home and husband, and bore all this fair family after her strange experience of the tomb.

Such events caused no slight panic at the time, and probably led to the custom, still kept up in many parts of Germany, of fastening a bell-pull to the hand of a corpse when laid in the public mortuary. Some cases of resuscitated cataleptics have even occurred in modern times, according to the statement made by Archbishop Donnet to the French Senate last spring.

Catalepsy may be a premonitory symptom of other diseases. Epilepsy has already been mentioned. De Haen relates, in a clinical lecture, a case he saw of a child of twelve, who began by being cataleptic, and ended by reciting the metrical Protestant version of David’s Psalms, saying her catechism with proof texts, and preaching a sermon on adultery.* And in several other stock cases, somnambulism seems to have been a complication. Marx saw a girl who became cataleptic from being frightened at a fire (like my patient at St. Mary’s), and afterwards went out of her mind.† In Goebel’s case of a young soldier, Catalepsy complicated the invasion of melancholia.‡ Sauvages says he saw an old man in the hospital at Alais, in whom Catalepsy alternated with quartan fever.§

Catalepsy seems to be sometimes voluntary, or, at least, capable of being brought on by very little external aid. Of this, St. Augustine gives an instance within his own knowledge:—

“There was a certain presbyter of the name of Restitutus in a parish of the diocese of Calami, who when he pleased (and he was often asked to do it by those who wished to have ocular demonstra-

§ Mémoires de l’Académie Royale des Sciences, &c. 1742, last page.
tion of the strange fact), just by having a noise made like as of some-
body crying, used to convey himself out of the influence of sensation,
and lie like a corpse. So that not only was he insensible to people
pinching and pricking him, but sometimes fire had been brought and
he burnt with it, without any sense of pain, except from the wound
afterwards. The body seemed to be motionless, not in consequence
of any voluntary effort, but from want of sensation, as was made the
more probable by the absence of any appearance of respiration, as in
a dead body: yet people’s voices, if they spoke out very clear, he said
afterwards he could hear as if they were a long way off.”*

Persons liable to this form in various degrees lose, by yielding to it
more and more, their power of voluntary control, so that exhibitions
of it are easily brought on by others who assume an influence over
them. They are told in a positive manner that they cannot raise their
limbs, cannot open their eyes, cannot feel, and they really seem to
lose temporarily motion, sight, sensation. Mesmer turned this arti-
ficial production of disease to profit (his own), and it has been largely
experimented upon of late years. But the unfortunate subjects of it
have brought to their masters so much “gain by their soothsaying,”
that deception has largely adulterated the real phenomena, and it is
difficult to find a genuine patient. For this reason I thought it
preferable to quote a case from a writer of unimpeachable shrewdness
and honesty, and far from credulous, though destitute of the light of
modern science, than to detail the experience of our own generation.

In the artificial disease and in the natural, somnambulism (clair-
voyance) is a frequent complication, as appears from several cases cited
by Tissot. (Œuvres, tom. xiii.)

It was not a groundless idea to suggest that, as we employ counter-
irritants to relieve an internal unmanageable inflammation by one
which is under our control and less injurious, so hysteria might be
cured by inducing in its place an allied malady more subject to our
will. But harm seems to be done by it, and probably only a limited
number of the English race have a suitable diathesis.†

Both in the natural and artificial disease there is exerted a very
different influence over the patient by different individuals. The
sight of Dr. Jebb’s face seems to have acted like the Gorgon’s head
in reducing his patient to instantaneous marble. My own experience
is quite the reverse. Strange nervous phenomena always seem to be
frightened away or subside into commonplace at my presence, and so
perhaps my report of them is printed in less bright colours than the
subject admits of.

Natural Catalepsy seems to become less frequent, or, at all events,
the symptoms less marked and strange, as the world gets older. Some
are even getting sceptical about its existence, and doubt the propriety

* Augustine, de Civitate Dei, lib. xiv. cap. xxiv.
† Those who wish to pursue the subject of mesmerism will find it treated of with the
broad views of a non-specialist by Feuchtersleben in his Medical Psychology, trans-
lated by the Sydenham Society.
of retaining it on our list of diseases. But even if it should be as extinct as the dodo or the great auk, this insult is uncalled for. The circumstances which surround the human race, especially when sick, are so altered, that it would be wonderful if some of the phenomena exhibited in pathological conditions were not altered too. Read the treatment adopted in many of the cases of Catalepsy quoted by the systematic writers. Take, for instance, that which M. Sauvages communicated to the Académie des Sciences,* where intermittent attacks of the disease occurred from time to time during several years. Though the patient was pale with a weak pulse, and though the blood could scarce be got to flow from the veins, yet she was bled, once from the arms, many times from the feet, and seven times from the neck. She had five or six repetitions of purgative medicine, not to mention *bouillons apéritives*, stomachic opiates, and twenty tepid baths, before they thought of giving her iron, which wrought a cure sooner than one could have expected. I lighted accidentally on another case communicated to the same scientific body by M. Imbert, in 1713.† It is that of the driver of the Rouen diligence, aged 45, who fell into a kind of soporific Catalepsy on hearing of the sudden death of a man he had quarrelled with. It appears that “M. Burette, under whose care he was at La Charité, made use of the most powerful assistances of art,—bleeding in the arm, the foot, the neck, emetics, purgatives, blisters, leeches,” &c. At last somebody “threw him naked into cold water to surprise him.” The effect surprised the doctors as much as the patient; it is related with evident wonder how that “he opened his eyes, looked stedfastly, but did not speak.” His wife seems to have been a prudent woman, for a week afterwards she “carried him home, where he is at present: they give him no medicine; he speaks sensibly enough, and mends every day.”

The “dame de Vesoul,” whom M. Tissot justly calls “la cataleptique par excellence,” so characteristic were the phenomena, was attacked during Lent, when she had been starving herself in order to give alms to the poor, and was also at the same time worried by a lawsuit which had brought her to Besançon. Yet she was bled in the foot. Fortunately, after three days, her friends took her home to Vesoul. What happened then the reporter says was quite as wonderful as her illness,‡ namely, that she had no more medical treatment, and yet got quite well, without a relapse.

I feel sure that the powerful assistances of art—bleeding, blistering, starving, purging, coddling, sympathising, and admiring—would have converted any of the cases under my charge into magnificent specimens of a long-continued intermittent disease.

But the fact of its being partly produced by art does not make Catalepsy a bit less of a reality, for the same may be said of all preventible diseases.

‡ “Ce qui ne surprendra peut-être pas moins que sa maladie.” Tissot, Œuvres, tom. xiii. p. 16.
Besides the effect of treatment, it is likely that the unrestrained manners and want of mental control peculiar to the barbarous ages of all nations, would render mediæval Europe liable to exaggerated exhibitions of all psychical defects. And, as psychical defects are indubitably hereditary, the national temperament would be thereby affected. As an example of what is alluded to, take one scene from early English history, and conceive it happening in the present day. Fancy four members of the Queen's Privy Council calling after lunch on a refractory archbishop who had voted against the ministry that had appointed him, with the intention of showing him the error of his ways. Fancy them scolding and blaspheming "by God's wounds," giving him the lie, "jumping up and leaping about," "throwing about their arms," "twisting their gloves," "raving like madmen." Fancy him, red in the face, defying them, rushing after them to the door, calling one his lackey, and another "a pimp." Yet this is only a part of the want of restraint shown by both parties when Reginald Fitzurse, William de Tracy, Hugh de Morville, and Richard Brito called on Archbishop Becket on the afternoon of December 29th, 1170.* The mere fact of the murder, with the nauseous details of how Tracy picked out the brains with his sword, is not half so strange as such a scene. How many generations does it take to produce descendants of such men free from nervous disorders?

The deficient vitality of which Catalepsy is a manifestation occupies that puzzling part of the circle of life which lies between spirit and matter. We know so little about the chain which connects the two, that its links are reckoned by us as few and short, and we have no names for them. Yet when we see the varied phenomena produced by breaches in the connexion, we are led to feel our ignorance of the subject, and to conjecture that these abysses of incertitude veil a long list of vital functions.

In default of names for even the normal functions of this department of life, we must not expect an accurate nomenclature for their aberrations from health; and the most we can do in attempting to classify them, is to observe how near their origin lies to one or the other extremity of the series of vital acts which are interfered with—what relation their phenomena bear on the one hand to mind, and on the other to body. We shall thus have a natural order with pure insanity at the one end, and epilepsy traceable to organic lesion at the other. In the middle will lie ecstasy, Catalepsy, and hysteria, with many a blank between for the anonymous transitional forms. I do not think we can spare any of these names, and instead of clubbing them together, as some would fain do, under the common head of "hysteria," it would appear more useful to divide that disease, according as its emotional, anaesthetic, hyperæsthetic, or convulsive phenomena are most prominent. I say it would be useful to make a main point in each individual case whether the malady is most related to deviation from mental or bodily health; for I feel convinced it is only by this

observation that we can avoid such disappointment as leads many to look upon hysteria, for example, as an opprobrium medicinae, which makes them feel the same sort of anger against it as is roused by moral guiltiness, and disposes them rather to punish than to cure the patient who has thwarted them.

Treatment.—As to the treatment of Catalepsy, it is probable that valerian and ammonia, administered in draught or enema, whichever is most convenient, together with a modification of what cured the Rouenese stage-coachman, namely shower-baths, will accomplish all that is wanted in the way of medicine for the slighter cases likely to come under treatment in the present day. In longer continued cases Dr. Jebb’s prescription of an opium plaster to the epigastrum, with tonics to the mucous membranes, is rational practice; for Catalepsy seems to depend much on the mucous membrane of the stomach, as is the case with its sister malady, hysteria. But I would strongly urge upon all who have the charge of these and similar semi-mental, semi-corporeal manifestations, to take the hint given me by the second patient, and try to acquire (surely it is to be acquired by trying) the habit of command. Let them exercise it in the direction of supplying the deficient will, not of paralysing it, of demesmerizing instead of mesmerizing their patients, and it is astonishing how much pharmacopeial medication will be saved to both parties.

Catalepsy may be sometimes feigned. For its detection the most cruel means appear sometimes to have been adopted by our forefathers, such as burning, pinching, cutting, putting into coffins, and otherwise frightening the supposed impostors. A caution is therefore needed, that the trial of these methods would in England very properly subject the experimenter to legal proceedings, the more so as they are quite useless, and prove nothing. No malingering could successfully feign the peculiar wax-like yielding resistance of a cataleptic muscle, and ought to be immediately detected by a medical man. If a doubt is felt, some expedient may be tried like that of Dr. Marx. Observing that really cataleptic limbs finally, though slowly, yield to the force of gravity and fall by their own weight, he attached some heavy body to the extended hand of a suspected impostor. She bore it up without moving; the intention of the experiment was explained, and she confessed her fraud.*

The points intended to be made concerning Catalepsy are these:—
1. That it is a rare pathological condition of mind and body, allied in its causes to hysteria, but not so apt to become chronic.
2. That it is not dangerous in itself, though it may be the precursor of dangerous disease.
3. That it may be artificially produced, but it is not easy to feign.
4. That the treatment, moral and physical, should be conducted on the same principles as the treatment of hysteria.

SOMNAMBULISM AND ALLIED STATES.

By Thomas King Chambers, M.D. F.R.C.P.

Somnambulism is a slumber so morbidly profound that resisting spontaneity is lost, and the obscure images, known as ordinary dreams, are able to exert a motor power. "Sleep-walking," where even the intricate concatenated motions necessary to preserve the body's balance are performed, is the most striking and dangerous exhibition of this state, and therefore has given a name to the disease; but it differs in degree only from sleep-talking, sleep-eating, and a form of nocturnal incontinence of urine and of spermatorrhoea. That it is not a partial waking is shown by the difficulty always found in fully waking a somnambulist, and also by the bewilderment and slow return of consciousness afterwards. This bewilderment, moreover, is often followed by headache and a clamminess of mouth, just like that of the condition known as "the intoxication of sleep" in those who have slumbered too heavily and too long. Again, decided somnambulists are entirely ignorant of what they have been doing during sleep; whereas dreams which occur during a partial waking are always remembered more or less. Again, the automatic acts done during partial waking are very short, have no continuity, and quickly end in a decided condition; whereas the acts of the somnambulist are consecutive one upon another. It seems impossible, therefore, to agree with Dr. Symonds, Hartmann, and others, who have regarded it as an incomplete sleep.

Still less can we agree with the superstitious awe which would represent it as an exalted state, in which the soul is freed from the trammels of the corruptible carcase. It is in truth a lower life, in which "the sceptre of reason is surrendered to a physically-directed fancy." (Feuchtersleben.) Instead of nearing the angels, man thus approaches temporarily the nature of ill-bred horses who refuse to lie down in their stalls, birds who roost standing on one leg, and gorged dogs who—

"Weary with the chase,
Lie stretch'd upon the rushy floor,
And urge, in dreams, the forest race
From Teviotstone to Eskdale Moor."

This morbid sleep usually arises in the first instance from eating too much. Perhaps the over-loaded stomach presses on the solar plexus,
and produces a partial paralysis in the coats of the arteries, and so in
the cerebral circulation. The explanation is the more probable, because
sleeping with the head too low is another predisposing cause, whose
action would be on the brain.

Strong mental emotion, excessive exertion of the intellect, violent
grief, love, &c. probably act in the same way; namely, by arresting
digestion and causing a weight at the stomach.

When, however, the habit is once established, it is persisted in even
after the gluttony or emotion has been discontinued. In this it
follows the rule of all morbid states of the nervous system, which
are peculiarly apt to be retained in spite of the removal of their
causes.

It is most common in youth, and at about the age of puberty. Then
the sexes are equally subject to it; but later in life it seldom
attacks men than women.

Somnambulism is sometimes hereditary. A young lady, about
whom I have been consulted a few times this summer, will often
(sometimes two or three days a week) go off in the evening into a
peculiar dreamy state. She talks and answers questions, though, after
an interval, walks about the house, goes to bed, remains quiet at
night, and sometimes recovers her ordinary condition on waking;
but sometimes her mother will go into her room and find her dressing
in a vague, dreamy way. After a while she will stare, stretch herself
like a person waking from sleep, and resume her natural lively
manner. Her memory is always quite blank as to anything said,
seen, or done during this dreamy condition. She has never had any
hysteric or epileptic fits. Such are the symptoms, and her father
asked me what name I should give to the disease. I hesitated at
first, and then said that some might call it perhaps Catalepsy, but
that the more proper name was Somnambulism. That was curious, he
observed, for his mother had been afflicted with what was called both
Catalepsy and Somnambulism, and he had heard it was in the family.
I have also recently understood that a younger sister of my patient
is falling into the same state, but I have not seen her. This lady had
occasionally got out of bed when in her unconscious state, but it
happened so seldom that no alarm on that score was expressed by
the family.

Somnambulism is inconvenient to other people from the fright it
causes, and dangerous to the patient from the awkward positions it
puts him in when unprotected by his reason. But it is by no means
inconsistent with a fair condition of general health. It is, for instance,
not unfrequent amongst boys and girls at school who bodily and
mentally are quite equal to their companions.

At schools accidental accesses of it are liable to be fostered into a
habit by the patient’s room-fellows talking to them, and otherwise
“drawing them out,” when in this state.

Like epilepsy, and indeed all diseases of the nervous system, it is
apt to become periodical. Some persons will walk, or talk, or wet
their beds, &c. once a fortnight, week, or month, and so on with great regularity. That does not arise from an accumulation of secretion or excitability; for at first, and while the original cause is predominant, several attacks occur often close together in succession, and then cease. It is rather an evidence of the weakness becoming constitutional, after the original cause has been removed.

Somnambulism has in some rare cases alternated with catalepsy, of which M. Sauvages has recorded an instance. (See Catalepsy.)

More generally it alternates with a normal state.

There are cases recorded where the somnambulistic sopors have been so frequent and so long, that there is as much of a sleeping as there is of a waking condition, and thus has arisen the singular phenomenon called "double consciousness." Trains of thought are carried on from one attack to the next, though in the normal interval the mind is quite unconscious of them. A remarkable instance of this is recorded by Dr. Dewar, in the "Transactions of the Royal Society of Edinburgh," vol. ix. p. 365. The patient, a servant maid, began by being subject to attacks of extreme sleepiness: then in these sleeps she began to be talkative. Soon there appeared more method in what she said: she personated an episcopal clergyman, went through the baptismal service for three children, and delivered an extempore prayer. Another time she was a jockey at Epsom, and rode round the kitchen on a stool. On awaking, all these pranks were quite forgotten. However, in the succeeding fit she remembered all that occurred. Thus, one night a villain indecently assaulted her when somnambulistic. On the morrow the insult was forgot, but shortly afterwards she had a fresh attack and told her mother of it. She got well after an emetic and the return of the catamenia, which had been absent.

Dr. Abercrombie adds two more cases related to him by non-medical persons, and perhaps for that reason accompanied by more wonderful phenomena. (On the Intellectual Powers, Pt. III. sect. iv. § 2, II.) In principle these phenomena are quite in analogy with healthy dreams, which scarcely ever take cognizance of recent facts of the waking state. For example, in my own dreams, though I had the misfortune to lose a leg two years ago, I always seem to walk about as in youth. And I certainly remember a room-fellow at school who used to talk in his sleep on a class of subjects he never mentioned by day, and who seemed to recollect when in the same state next night that he had spoken of them before. But that an education should be carried on, and languages acquired, during somnambulism, as some strange stories record, is hard to credit. Possibly some confusion existed in the minds of the observers, and they mistook the waking for the sleeping state.

Somnambulistic phenomena have sometimes accompanied the artificial catalepsy of the mesmeric trance. They are called "clairvoyance," not that the patients see particularly clearly, but that the common sensorium is very receptive of those slight suggestions which it would
neglect at other times, when its attention is occupied with the external world; and so they appear to careless observers to see with the tips of their fingers, the epigastrium, &c. when their eyes are closed. Singular exhibitions are thus produced. But with practice this rapid obedience to slight suggestion is soon acquired by even stupid people; so that jugglers have no difficulty in obtaining sham cases for shows, by no means easy of detection. This prevents the investigation of the subject by scientific persons.

TREATMENT.—1. The patient must be removed from the company of those who would be disposed to foster into a habit by experiment the recent establishment of the disease. This applies particularly to young persons at school, and those brought under the dominion of mesmerizers.

2. The patient must be prevented from falling into that morbidly deep sleep in which the special phenomena of the case are produced. This can be accomplished by waking them up once or twice in the night, before they begin to walk, talk, or do other unseemly acts. It may be done with great advantage during the second hour of sleep in cases of simple sleep-walking and of bed-wetting.

A young lady under my care who used to rise and make water on the floor without being aware of it, was relieved by this means.

M. Troussseau* knew a wealthy and beautiful girl, from whose feet whores had been driven away by an incontinence of urine occurring nightly. At last the impediment to marriage was overcome by a hero. M. Troussseau cynically calls him "un individu sans fortune;" but poetic justice requires a better motive for an act so richly rewarded; for, like the knight of whom the Wif of Bath tells, he found her "bothe faire and good," when expecting, like him, only the latter; the disgusting affliction vanished straight away—

"And thus they live unto hir lives ende
In parfit joye"—

at least they have the chance of doing so. Doubtless it was the prevention of over-profound sleep which cured her.

Some years ago a foolish young man from the country brought for my opinion an instrument which he had purchased of an advertising quack, designed to cure spermatorrhœa by compression of the urethra and prostate. The disease in this case, being purely imaginary, was of course incurable. But I should not wonder if the plan had been found useful, acting as an obstacle to morbid sleep. However, it would require careful medical superintendence.

A clergyman (who corresponded with me anonymously, and therefore I can say nothing of his general health) took by my advice, unsuccessfully, several remedies, till he suspected that he abused himself during sleep; he tied his hands by a string to the bedpost, was woke up several times a night, and cured.

* Clinique Médicale. Lecón LX.
Another patient, really troubled with involuntary emissions, cured himself by having an alarum which he set so as to awake him occasionally in the night.

Other attacks of spermatorrhoea I have found take place during the abnormally heavy morning doze which lazy people indulge in, after they have really had enough rest—the intoxication of repose. These patients should be told to get up and dress immediately after their first awaking. It soon cures them.

3. Care should be taken that the head lie high in the bed, and that the body be not covered with too great a weight of clothes.

The son of an old and intimate friend of mine used to suffer when, a child from incontinence of urine. Soon after puberty this inconvenience ceased and has not returned. But at eighteen he has come to me complaining of seminal emissions, which have occurred on a few occasions more than once in a night. On inquiry he said that on waking up after a defilement, he had often found his head right under the bolster. He was advised to be careful in keeping a good hard pillow well down under the shoulders, and he has not suffered since.

4. Though prevention by means of keeping off too profound sleep is desirable, yet patients should not be wakened when walking, or in any other unnatural posture. They should be led back quietly to bed

"Donec discussis redeant erroribus ad se."

Otherwise the fright is dangerous, especially to hysterical persons.

5. Light meals and digestible food are essential, and those special expedients should not be trusted in till the general health has been brought up to the average.
CHOREA.

BY C. B. RADCLIFFE, M.D., F.R.C.P.

Chorea, the St. Vitus's dance of this country, the dance of St. Weit, of Germany, and the dance of St. Guy, of France—St. Guy being the French equivalent of St. Vitus, or St. Weit—is sketched for the first time in the writings of the English father of medicine. "St. Vitus's dance," says Sydenham, "is a sort of convulsion which attacks boys and girls from the tenth year until the time they have done growing. At first it shows itself by a halting, or rather an unsteady movement of one of the legs, which the patient drags. Then it is seen in the hand of the same side. The patient cannot keep it a moment in the same place; whether he lay it upon his breast, or any other part of the body, do what he may, it will be jerked elsewhere convulsively. If any vessel filled with drink be put into his hand, before it reaches his mouth he will exhibit a thousand gesticulations, like a mountebank. He holds the cup out straight, as if to move it to his mouth, but has his hand carried elsewhere by sudden jerks. Then, perhaps, he contrives to bring it to his mouth; and if so, he will drink the liquid off at a gulp, just as if he were trying to amuse the spectators by his antics."

In this sketch no notice is taken of certain features of the disease which are sufficiently characteristic. It is not shown, for example, that not unfrequently the speech is so thick and hesitating as to be not easily intelligible, and the tongue so fidgety as to make it no easy matter to get a distinct look at it. Many touches are indeed wanting to complete the portrait, but the sketch, nevertheless, is one which could only have been drawn by a master, and which can never be copied too often in a history of chorea.

As its symptoms are toned down on the one hand, or exaggerated on the other, St. Vitus's dance may be a very trifling disorder, or a very grave malady.

In its most trifling form chorea may be nothing more than a grimace, or a shrug of the shoulders, or a catch in the speech, or some other odd or awkward involuntary movement, which, in many instances, appears to be little more, or no more, than an unchecked bad habit.

In its gravest form, few diseases, if any, are more distressing to the spectator. In the ordinary form, the muscles are not always in motion, and sleep is a time of quiet: in this form the state night and day is
one of ceaseless tossing to and fro. In this form, indeed, not only do the incessant workings of the muscles render such acts as handling, or standing, or walking, impossible, but they even prevent the patient from remaining in bed without being strapped down, or fenced in. In the ordinary form, the twistings of the features are amusing rather than otherwise: in this form the grimaces can scarcely be seen on account of the "piteous imploring" expression which is mixed up with them. In the one case, it might be supposed that the patient wished to be funny: in the other, an appeal for help is plainly written on the countenance, which is all the more distressing from the inability of the spectator to render help. In the ordinary form, the articulation at most is only thick and hesitating: in this form all speech is impracticable, and the only sounds uttered are "an occasional involuntary squeak or cry." In this very grave form of the disease, also, even deglutition may be impracticable. Once, seen, indeed, it is not easy to forget a scene so sad as that presented by a patient thus turning and writhing and tossing, with, very probably, his lips torn and bleeding from being, in spite of all he can do to prevent it, drawn incessantly into the mouth and munched between the teeth, with the elbows, and hips, and other prominent points made raw by constant rubbing against the bedding—a sight which is forced upon one, for no care is sufficient to keep the bed-clothes in their place,—and never at rest until he sinks, not unwillingly, into that sleep from which he can only wake in another state of being.

Allied more or less closely to this severe form of chorea, is a disease which was first described by Dr. Dubini, of Milan, about twenty years ago, under the name of electric chorea. This disease seems to be peculiar to certain districts of Lombardy. Its symptoms are:—

(1) Certain choreic or convulsive shocks in the limbs, repeated with a certain regularity of rhythm, persisting with scarcely any intermission for days, or even weeks, and followed by paralysis, and, it may be, atrophy of the affected parts; (2) certain tonic convulsions of great violence, affecting the muscles in which the choreic convulsions are manifested, and occurring in not unfrequent paroxysms; (3) epileptiform attacks, sometimes general, sometimes partial; (4) certain head-symptoms, such as cephalalgia, delirium, and coma. One or other of these groups of symptoms may be predominant in different cases. Electric chorea may be either acute or chronic, and in either case its termination is almost always in death. As a rule, it begins quietly, and is in no great haste to assume its serious characters. As a rule also, a delirium, lasting for some days and ending in coma, ushers in the fatal termination; but not unfrequently death is brought about more speedily and suddenly in an epileptic paroxysm. The electric shocks, which form so conspicuous a feature in the disorder, occur very frequently, as often as thirty, sixty, or a hundred times in the minute, and they are often, if not always accompanied by feelings of pain, tingling, or cramp in the same parts, by vertigo, and by humming, or singing sounds in the ears.
At first the digestive organs are but little affected, but after a time the appetite fails, and gastralgia and frequent vomiting add to the distress. Fever, indeed, is not seldom present. The mean duration of the disease is from forty to seventy days, if we except a few acute cases in which death happened in a few days with urgent cerebral symptoms.

Electric chorea was the name chosen for this disease by Dr. Dubini; typhus convulsivo-cerebralis was the name selected by Dr. Frua, a colleague of Dr. Dubini's in the same great hospital in Milan, who saw many cases, and whose description of the disease immediately followed that of this last-named physician; and myelitis convulsiva was the name made use of by Dr. Hörtel, in his account of the disorder. This difference of nomenclature shows how differently different observers were struck by what they saw, and proves, at the same time, what is plain from their description, that electric chorea has not, perhaps, the strictest claim to be admitted into the category of choreic affections.

St. Vitus's dance, however, is the very Proteus of diseases, and many strange maladies have to be passed in review before the description of all its various forms is complete.

The disease to which the name of St. Vitus's dance was originally given was of an epidemic character. It broke out at Strasburg in 1418, close upon the heels of the black death. It was, in fact, a fresh outbreak of a dancing epidemic called the dance of St. John, which made its appearance at Aix-la-Chapelle in the summer of 1374, and then spread like wildfire over the whole of Germany, and the countries to the north-west. This dance of St. John appears to have been characterised chiefly by paroxysms of extravagant dancing and leaping and howling and screaming. In some cases the head was filled with ecstatic visions in which St. John was a prominent object; in others, the most frantic excitement was produced by certain sights or sounds. Sometimes the dancing movements were ushered in by symptoms of an epileptiform character: usually they were accompanied and followed by the most distressing flatulence: almost always they were carried on until they came to an end from sheer want of strength. For nearly two hundred years society was disorganized by persons suffering from this demoniacal disorder, and by rogues who simulated it for sinister purposes. Dr. Hecker tells us that the feast of St. John the Baptist was always held as a day of wild revelry; and that at the time when this strange malady made its appearance, the Germans were in the habit of mixing up with this Christian ceremonial an ancient pagan usage—the kindling of the "nodfyr." It was the custom on these occasions to leap through the flames of this fire, and to consider that a year's immunity from the disease was gained in this way; and in this leaping run mad, Dr. Hecker thinks, we have the origin of the dance of St. John.

In its main characteristics the dance of St. Vitus does not appear to have differed from the dance of St. John. The difference of name
was owing to this—that at the first appearance of the disease in Strasburg, the sufferers, real or pretended, were so numerous that the city authorities divided them into companies, and appointed persons whose duty was to conduct them to the chapels of St. Vitus near Zabern and Rotenstein, as well as to protect and restrain them by the way. They were taken to these chapels in consequence of a legend, invented conveniently for the occasion, which represented that this St. Vitus, when suffering martyrdom under Diocletian, in the year A.D. 303, had, in answer to prayer, received power to protect from the dancing mania all those who observed the day of his commemoration, and fasted upon its eve. At any rate, to the shrine of St. Vitus these people went, and there priests were ready to sing masses, and to perform other services fitted for the occasion; and thus the name of the disorder became changed from the dance of St. John into the dance of St. Vitus.

Attention was first prominently directed to these two dances, at the times which have been mentioned, but there is good reason to believe that they had been known a long time previously.

At the beginning of the sixteenth century, a change had taken place by which these disorders had become less unlike disorders which are now classed under the head of chorea. This is evident from the description given by Paracelsus and other competent observers. At this time these maladies were characterised by frequent fits of hysterical laughing or crying, by odd movements, and now and then by fits of dancing, but not by the howling or screaming or mental delusions or distressing flatulence of former days. In some instances, also, the propensity to dance was not irresistible. Still, now and then the disorders in question appeared in their old form, and Dr. Hecker tells us that so late as 1623 some women were in the habit of paying a yearly visit to the chapel of St. Vitus, in the territory of Ulm, in order that a dance at the altar there might save them from dancing against their will until the same time next year.

Almost contemporaneously with the dance of St. Vitus, a dancing malady, called tarantism, appeared at Apuleia, and spread from thence with great rapidity over the rest of Italy. This malady was attributed to the bite of a tarantula, or ground-spider, common in the country; but it is more probable that undue fears as to the evil consequences of the bite—fears arising easily in the gloomy and despondent temper of the times—had more to do in causing the malady than the bite itself. Those who were bitten remained dejected and stupefied, or else, becoming greatly excited, they went about laughing, singing, or dancing. In any case, they were utterly unable to restrain themselves if acted upon by music of a certain kind. A bacchantic furore was excited by the first notes, and as the performance went on they would dance, and leap, and shout, and scream, until they fell down from sheer exhaustion. Some colours appeared to have excited them, others to have calmed them. Some had a strong disposition to rush into the sea; many were carried away by
strong sensual passions into deplorable excesses. Some, again, were tormented by the flatulent distress which was a symptom in the dance of St. John. In this malady, music was looked upon as the only remedy, and the country everywhere resounded with the merry notes of the tarantella. The favourite instruments were the shepherd's pipe and the Turkish drum. It was supposed that the poison of the tarantula was diffused over the system by the exercise of the dancing, and expelled along with the perspiration. It was customary for numerous bands of musicians to traverse the length and breadth of the land during the summer months, and the seasons of dancing at the different places were called the women's "little carnival," "carnavaletto delle donne," for it was the women, more especially, who conducted the arrangements, and defrayed the expenses. Tarantism continued in Italy long after the dance of St. Vitus had died out in Germany; indeed, the epidemic can scarcely be said to have been at its height until the middle of the sixteenth century.

It would seem also that the tigrotier or dancing mania of Abyssinia, a malady occurring most frequently in the Tigre country, is, in some respects, not unlike the ancient dances of St. Vitus and St. John. Beginning with violent fever, this malady soon turns to a lingering sickness, in which the patient becomes reduced to the last degree of emaciation and exhaustion. This sickness may continue for months, and end in death if the proper cure be not sought after. The first cure, which is also the cheapest, is one in which a priest ministers. It is a kind of water cure, with a blessing superadded. If this fail, the aid of music is appealed to, and arrangements are made for a prolonged performance. The place chosen generally is the market place. Under the influence of the music the patient soon bestirs herself, and begins to leap and dance in the maddest manner possible, and having begun, she goes on in the same way until the day is nearly, and the musicians altogether, spent, and then she starts off, and runs until her legs refuse to carry her any further. Then a young man who has followed her fires a gun over her head, and striking her on the back with the flat of a broad knife, asks her name, when, if cured (she had never uttered this name during her strange illness), she repeats her Christian name. After this she is re-baptized, and considered convalescent. The account of this extraordinary affection is by Mr. Nathaniel Pearce, who lived nine years in Abyssinia, who saw what he describes, and who published the story about thirty years ago.

A place in this strange category of disorders must also be conceded to those extravagant capings and dancings which have been met with at various times among certain sects of religious enthusiasts—the jumpers of this country and America, the "convulsionnaires" in France, and the victims of "leaping ague," who, some time ago startled and shocked the grave people of Scotland. These latter enthusiasts complained of pains in the head and elsewhere, and soon afterwards they began to suffer at certain periods from fits of convulsion and fits of
dancing. At these times they acted in the maddest way, distorting their bodies, springing to a surprising height, or running with amazing velocity until they fell down exhausted. When confined in cottages, a favourite practice was to leap up and swing about among the beams supporting the roof. The effects of music do not appear to have been tested.

The time for a general visitation of maladies such as these, would appear to have passed by, at least, in this country; but there are still to be met with, now and then, isolated cases which have some claim to be included in the same category—cases distinguished by involuntary leaping, turning, or rushing backwards, forwards, or sideways. One of these, often quoted before, is recorded by Mr. Kinder Wood; and this, with two which have fallen under my own observation, may serve as illustrations.

Mr. Kinder Wood's patient was a young married woman who had suffered for some time from headache, nausea, quick involuntary movement of her eyelids, and various contortions of the limbs and trunk. The paroxysms themselves were not always of the same kind. At one time she would be violently and rapidly hurled from side to side of the chair in which she might happen to be sitting, or else, suddenly gaining her feet, she would go on jumping or stamping for a while, or she would rush round and round the room and rap with her hand each article of furniture that lay in her course. Or she would spring aloft many times in succession, and strike the ceiling with the palm of her hand, so that it became necessary to remove some nails and hooks which had done her an injury. Or she would dance upon one leg, with the foot of the other leg in her hand. These movements always began in the fingers, and the legs were not affected until the arms and trunk had been first seized upon. Noticing a rhythmical order in some of her movements, as if they were obedient to the memory of some tune, a drum and fife were procured, and the result of playing upon these instruments was, that she immediately danced up to the musicians as closely as she could get, and continued dancing until, missing the step, she suddenly came to a standstill. On another occasion a continuous roll of the drum at once put a stop to the dancing movements. Afterwards, the drum was used in this manner with the happiest results, and at the end of a week these movements may fairly be said to have been stopped and cured in this way. Unfortunately, however, the drum and the fife were alike found to have lost the power on two subsequent occasions when the dancing recurred. These strange paroxysms were generally accompanied by some headache and nausea, and followed by a feeling of great weakness and exhaustion, but the patient was always able to go about her household duties in the interval.

A young lady, between twelve and thirteen years of age, who had suffered for about three years from a choreic practice of "making faces," and bobbing her head forwards in a curious manner, was the patient in this case. About three weeks before the date of my
first visit (24th June, 1857) she suddenly began to suffer from the paroxysms which have now to be described, and a few months previously she had suffered for some weeks in a similar manner. In one of those paroxysms she would sink or rise into a sitting posture, with her legs folded under her, and then her head would be agitated by a violent, alternating, semi-rotatory movement, until the hair would stream out horizontally on all sides, like the strands of a mop when twirled over the side of a vessel. Then followed a movement in which the whole body was thrown round and round by a succession of rapid vaults. In making these vaults, the hands were placed upon the floor or bed, and the arms used as a kind of leaping-pole; and except at the instant of swinging round, when the feet and legs were thrown horizontally outwards, the half-sitting, half-kneeling posture was never abandoned. The movements of alternating semi-rotation of the head, and of circumvolution of the whole body, occurred separately and without any order, and lasted from a few minutes to half an hour. At their worst the paroxysms were only separated by short intervals; and it is difficult to say whether the movements themselves or the state which followed—a state to which the patient lay panting, dripping with sweat, and exhausted to the last degree—were most distressing to witness. Paroxysms such as these occurred several times a day during the first fortnight of my attendance, and then ceased suddenly. After this the patient rapidly improved in general health, and the choreic twitchings of the muscles of the face and the bobblings of the head became much less frequent. This improvement, however, was only temporary, and at the end of three months the fits returned, though in a modified form, and much less frequently. At this time, indeed, the alternating semi-rotatory movement of the head did not return, and the movement of circumvolution was varied by other movements. Thus, instead of turning, the patient would at times make a succession of leaps in a straight line, so that it was necessary to run in order to prevent her from rushing out at the foot of her bed; and now and then, after falling back exhausted at the end of such a paroxysm, she would roll over and over sideways for three or four times. During these strange attacks there was not the least trace of stupor, and she would often complain of pains in her head, or of being excessively tired even while the muscular disturbance was at its height. In some instances after the relapse, however, her mind was in a rapt or entranced state, and now and then words escaped which showed that she was absorbed by some alarming dream or vision. At those times the eyes had a fixed stare, and the cheeks were somewhat flushed. After the paroxysm she would be for some time in an intensely nervous and excitable state, starting at the slightest noise or the gentlest touch, and now and then bobbing her head with much violence; or, if the mind had been entranced while the movements were going on, this state would continue for some time, and then pass off with a succession of sighs. Ordinarily, however, the mind was perfectly clear, and the first moment of rest was occupied in complain-
ing of the feeling of headache and fatigue from which she suffered. In the intervals, the patient was nervous and excitable, but in every respect an acute, clever, accomplished, amiable girl. At these times her principal complaint was of a dull pain across the top of the head, or of a feeling of tingling in the back and limbs. In this case, the pulse was quick and weak, the hands and feet were habitually cold, chilblains were scarcely absent in summer, anaemic sounds were audible in the heart and great vessels, the appetite was very defective, and the digestion sluggish. There were no worms or any other evidence of derangement in the alimentary canal beyond a slight disposition to tympanitic distension of the abdomen. Nor was there the slightest evidence of uterine derangement; indeed, in this point of view, the patient was a mere child. Recovery was tedious, and more than once interrupted by a relapse, but it was complete in the end; so complete, that there was no relapse when menstruation was established about twelve months later.

The next case is that of a young gentleman, Mr. E——, æt. 22, who came up from the country, about six years ago, to consult me for what he considered to be epileptic attacks. These attacks he had, but he also had other attacks, for the sake of which I now refer to the case. In the first place, he had a curious pursing up of the mouth, attended with frequent shruggings of the right shoulder, and frequent tossings out of the right leg: in the next place, he had attacks of shuddering, which were so violent as to shake things out of his hand, or to pitch him bodily out of the chair in which he might be sitting, or even out of the bed in which he might be lying; in the third place, he had what he called a "fit of turning." He had scarcely told me this story, when, after two or three shudders, as if a shock of electricity had been passed through him, he got up from the chair on which he was sitting, and began to turn slowly on his heels upon the hearthrug. He turned round and round in this way perhaps twenty times, and then sat down. Before getting up from the chair, he told me not to be surprised at what I saw, and begged me not to attempt to stop him. He said, moreover, that the impulse to turn was not altogether irresistible, but that he could not resist the impulse successfully without being much agitated afterwards. This gentleman had gained honours at college, and there was no reason to conclude that his mental powers were at all impaired. He had suffered for some time from vertigo, and now and then from headache, but never distressingly so. His pulse was 60, and weak, and during one of the paroxysms which I have described, it fell full 10 beats, and became much weaker. I noticed, also, that the breathings were slow and embarrassed, and that he drew several long breaths in succession as soon as the paroxysm was over.

It is also customary to regard as varieties of chorea those distressing and not very uncommon cases in which the head is affected by semi-rotatory, oscillatory, bowing, or bobbing movements. These movements are very varied in character and degree: they may be combined
in various ways; and not unfrequently one kind changes into another in no very regular or intelligible order. The contractions giving rise to these movements may take place suddenly or gradually; very often they recur with monotonous regularity so long as the patient is awake; in some instances they may now and then be suspended for a time by a strong effort of the will, or by holding the head firmly between the hands: not unfrequently they are accompanied by muscular contractions elsewhere, especially when the patient begins to be worn out by want of sleep and annoyance, and in some degree by bodily suffering also, for, after a time, the muscles affected become very sore, especially about their insertions, and the contraction is attended with a good deal of pain.

Nor does this exhaust the list of affections which have or are supposed to have some relationship to chorea. On the contrary, it remains to mention certain movements which are, often at least, little more than bad habits or awkward tricks, such as semi-uncontrollable winkings, grimacings, and other movements which are sometimes spoken of as tics-non-douloureux. Nay, even stammering, stuttering, giggling, sneezing, and some forms of hysterical coughing, are not excluded, nor yet the convulsive shakings which are often seen in certain paralysed parts, or the jerks and starts which are not unfrequently met with in connexion with epilepsy. In fact, the term chorea is of the widest and loosest significance; for it is scarcely too much to say that it is made to include every form of disorderly involuntary movement, partial or general, which has not altogether the specific characters of tremor proper, or convulsion proper, or spasm proper.

Nor are irregular movements of one kind or another the only indications of disorder of the nervous system which are to be met with in cases of chorea. On the contrary, the fact appears to be, that there is always a disposition more or less marked to mental deficiency, paralysis, or numbness, one or all.

The mental flaw may show itself in dulness, apathy, irritability, and in various other ways; and it always does show itself in a greater or less degree in one way or another. In some cases (I am speaking now of chorea in its ordinary form) there is an expression of countenance which may even suggest the idea of idiocy; and cases have actually occurred in which a patient suffering from chorea has been mistaken for a simple idiot by being seen for the first time at a moment when the choreic movements were absent. At the best, the patient is in the state which is usually designated as "nervous."

Want of muscular power is shown by the readiness with which the patients become tired, and by the slowness with which they recover from fatigue, as well as in the soft, flaccid, and wasted condition of the muscles, when the disease has continued for some time. But this is not all which may be noticed, especially in those patients in which the choreic movements are confined to one side; for, in these cases, there is usually a want of power in the affected muscles
which must certainly be spoken of as a slight degree of paralysis. This want, as Sydenham said, "often shows itself by a halting, or rather unsteady movement of one of the legs, which the patient drags;" or, still more frequently, it may show itself in the helpless way in which the arm almost immediately falls when it is held out, for it is easy to see that this falling is a phenomenon which has much more to do with paralysis than with choreic movement. Moreover, it must also be borne in mind, as tending to bring into connexion the phenomena of chorea and paralysis, that in many cases of paralysis, properly so called, the affected muscles are the seat of movements which, by common consent, are placed in the category of chorea.

Errors of sensation are less common in chorea than errors of motion. Numbness is sufficiently marked in many cases to be detected without difficulty, especially in the parts in which the choreic movements are most marked, but it is never as prominent a symptom as in hysteria; and the same remark applies to over-sensitiveness to pain. Sometimes erratic pains, seemingly rheumatic in their character, are complained of, but in the majority of cases no mention is made of this symptom.

As may be expected, also, the signs of disorder which are met with in chorea are not confined to the nervous system.

Very generally there are signs which indicate, to say the least, a disposition to chlorosis—coldness and clamminess of the hands and feet, paleness of the lips, gums and tongue, pastiness or puffiness of certain parts of the skin, anaemic vascular murmurs, a disposition to chilblains, and the rest. In this country, moreover, there is a connexion between rheumatism and chorea which cannot be overlooked. In his excellent digest of 300 cases of chorea, occurring in Guy's Hospital, the late Dr. Hughes ascertained that, "out of 104 cases in which special inquiries were made respecting rheumatic and heart affections, there were only 15 in which the patients were both free from cardiac murmur, and had not suffered from a previous attack of rheumatism." Nor is it possible to get over this fact by supposing that the pains of the supposed rheumatism may have been simply neuralgic, and the cardiac murmur merely anaemic, for in 11 out of 14 cases of death from chorea recorded in this paper, there were actual vegetations upon the cardiac valves. It is not to be supposed, however, that the chorea and rheumatic fever were actually concurrent in these cases. On the contrary, the fact is, that the patient is said to have suffered from a previous attack of rheumatism, and that, in the majority of instances, there was an interval of weeks or even months between the two disorders. Moreover, the connexion which exists in this country between rheumatism and chorea does not appear to exist in Germany; for we find Dr. Romberg saying, "The rheumatic predisposition, noted by English medical men, was rarely traceable in the cases which have presented themselves to my observation." The connexion between rheumatism and chorea, how-
ever, be it intimate or not, cannot be twisted into an argument for believing that the phenomena of chorea are associated with a state of feverish activity of the circulation. In fact, chorea appears to be an essentially feverless malady—a malady which may occur in persons prone to rheumatism before or after rheumatic fever, when the habitual state of the circulation is below the average in activity and vigour, but never concurrently with rheumatic fever. This is the plain fact. Indeed, the very connexion of chorea with rheumatism, when properly understood, may be only one other proof that chorea is associated with a state of wanting vigour and activity in the circulation, for most assuredly a weak circulation and a lymphatic habit generally is the state of things which is likely to be present in persons who are prone to rheumatic fever.

In nearly all cases of chorea the digestive organs furnish indications of disorder—capriciousness or want of appetite, depraved taste, slow and painful digestion, constipation, and so on. In some cases the urine seems to be of unusually high specific gravity, as has been shown, first of all by Dr. Walshe, and afterwards by the late Dr. Todd and by Dr. Bence Jones. In a case of acute chorea, of which Dr. Walshe gives the history in detail, lithates were deposited in large quantities during the first few days, then urea was found to be present in great excess, then oxalates made their appearance, and last of all there was a copious precipitation of oxalates; and in another case, given in the Clinical Lectures of Dr. Todd, the specific gravity of the urine was never below 1-019, and often as high as 1-030 or even 1-035, and as a rule urea, and oxalate of lime, but especially lithates of ammonia, were present in considerable excess. The state of the urine requires to be more carefully inquired into. In two cases I found, for a short time only, some excess of urea, and a thick deposit of lithates on cooling; but this state of things soon changed, and what I noticed chiefly was the rapidity with which the urine lost its acidity, and threw down phosphates. And, speaking generally, I should say that this disposition to become rapidly phosphatic, is the change which I have most frequently noticed in the urine in chorea. In chorea, moreover, it is easy to see that the urine is not pale and copious as it is so often in hysteria, and also that the indications of uterine disorder are absent, which are so often present, or presumed to be present, in hysteria. At any rate these latter remarks are true of the common cases of chorea as seen in children and young persons.

Sydenham states that chorea, for the most part, attacks children between the tenth and fourteenth year of their age, who have not reached the time of puberty. Sir Thomas Watson considers these limits to be too narrow, and extends them to the period of the second dentition on the one hand, and to that of puberty on the other; nay, he extends them still wider, for he states that now and then, but only exceptionally, cases occur as early as 4 or 5, and as late as 20 or 25 years of age. Up to 9 years of age the two sexes appear to be equally liable;
after this age females become much more liable than males, even in the proportion of nearly 5 to 2.

In many cases there is a distinct flaw in the family history, especially in the direction of disorders of the nervous system. Thus, out of 48 cases, in which I have inquired into the family history, I find 27 cases in which father or mother or brother or sister had been, or was, the subject of one or other of these disorders—paralysis, epilepsy, apoplexy, hysteria, or insanity.

The predisposing and exciting causes of chorea would seem to be those which are common to other diseases of the nervous system. Sometimes a special cause of irritation can be discovered—as worms, carious teeth, and so on; in rare cases the fact of pregnancy would seem to be a determining cause; not unfrequently the starting-point may be found in fright or fatigue. In a word, nothing at all special has to be noted under the head of causes, either remote or immediate.

The natural tendency of common chorea is, without doubt, towards recovery. Sooner or later, within limits which have yet to be determined, the patient gets well. The malady is apt to recur, more than once it may be, and each relapse, as a rule, is milder and briefer than the attack immediately before it. Local chorea, as exhibited in the muscles of the neck at least, is notoriously obstinate; and instead of wearing itself out it is more likely to go on year after year until the patient is worn out by it. Acute chorea, in spite of all that can be done, is a malady which too often terminates fatally, and which, not unfrequently, does this by merging in some grave disease of the spinal cord or brain. How far the occurrence of chorea implies a tendency to other disorders of the nervous system, especially to epilepsy, is a question which has not yet been fully entertained, and I cannot supply an answer from actual statistics. But this I may say—that I have frequently met with epileptic patients who were choreic at one period of their life, and that the impression left on my mind from what I have seen is, that the chances of chorea being followed sooner or later by some other disorder of the nervous system are too much made light of.

Chorea cannot well be confounded with other maladies. It cannot well be confounded with hysteria. In exceptional cases, as in the original dance of St. Vitus and in other cases of the kind, the hysterical element may have figured conspicuously, and when this is so there can be no great difficulty in eliminating it; but in ordinary cases of chorea there is nothing to suggest the idea of hysteria, and therefore no cause of confusion on this score. Nor need chorea be confounded with other diseases of the brain and spinal cord. In acute chorea there is a tendency to run into one or other of these affections, and the moment of transition may not always be easily definable, but, as a rule, the accession of the new disease will, I believe, be indicated by the cessation of the choreic symptoms, and by the substitution for them of cephalalgia, delirium, convulsion, paralysis, numbness, pain in the back increased by movement, and
others, in groupings which will leave no doubt as to what their true meaning must be. I have seen two cases of chorea in children which ended in cerebral meningitis, and in which the choreic movements ceased when convulsion and delirium made their appearance; and I have seen one case of severe chorea in a youth which ended in inflammatory disorganization of a considerable portion of the spinal cord, and in which the choreic symptoms did not continue after the development of the numbness, paralysis, and other symptoms of myelitis. Indeed, it may be stated broadly that the symptoms of chorea are not the symptoms of acute inflammatory affections of the substance of the brain and spinal cord, or of their meninges. Nor in reality need chorea be confounded with any chronic affection of the membranes or substance of the brain or spinal cord, for in each one of these, not excepting even locomotor ataxy, the points of difference are much more numerous than the points of resemblance.

The part of the nervous system which is primarily at fault in chorea is not easily to be fixed upon with absolute certainty. Experimental physiology teaches that movements of a rotatory character may originate in various parts of the nervous system—in the thalami optici, corpora quadrigemina, crura cerebri, pons Varolii, crura cerebelli, in certain parts of the medulla oblongata, and also in the upper portion of the spinal cord; that choreic agitation may be caused by slicing away the cerebellum, and by puncturing one of the corpora quadrigemina; that the removal of the encephalon in front of the thalami optici may result in an impulse to go forwards; and that a deep wound in the cerebellum may be attended by an impulse to go backward. "The parts injured," says Dr. Brown-Séquard, "seem to be quite different from those employed in the transmission of sensitive impressions or of the ideas of the will to the muscles, at least in the medulla oblongata and pons Varolii. They constitute a very large proportion of these two organs, perhaps three-fourths of the first one: they are placed chiefly in the lateral and posterior columns of these organs: they seem to contain most of the vaso-motor nerves, by which, directly or through a reflex action, they may act on other parts of the nervous system: and they can give rise to spasm on the same side of the body—a fact which shows that many of their fibres do not decussate." Moreover, another lesson to be learnt from experimental physiology is, that rotatory movements may have their starting-point in a nerve at a distance from the nervous centres. Thus, Dr. Brown-Séquard has made a rabbit turn or roll towards the injured side by puncturing the expansion of the auditory nerve within the ear; and M. Flourens has produced similar movements in a pigeon, by simply tying a bandage over one of its eyes. It would seem, indeed, as if the parts of the nervous centres which are concerned in the production of choreic movements may be affected from a distance by reflex action. Nor is this to be wondered at, seeing that there are facts without number which show that distant parts of the nervous system are continually being affected by reflex action, and that the varied consequences of a particular injury are
only to be accounted for by supposing many of them to be reflex phenomena. Indeed, there is no lack of instances to show that any part of the nervous system may act on any other part, and the exact localisation of many disorders of the system is a difficult, if not hopeless task, for the simple reason that any given lesion in any part may be attended by a wide range of symptoms depending upon sympathetic disorder set up in other parts.

Nor do the disclosures of the dead-house tend to give a very definite locality to the lesion of the nervous system of which chorea is the consequence. Thus, in fourteen cases of deaths from chorea, collected by the late Dr. Hughes, the brain was quite healthy in four, and only congested in three cases, while of the remaining seven cases the particulars are these:—in the first, serous effusion beneath the arachnoid and into the ventricles, slight effusion of blood beneath the right cerebral hemisphere, softened brain; in the second, arachnoid opaque, brain dark and soft; in the third, pia-mater watery, cineritious matter, red, soft, and partially adherent; in the fourth, brain soft and vascular, much fluid in ventricles; in the fifth, arachnoid opaque in parts, cerebrum vascular, left thalamus rather soft; in the sixth, dura-mater adherent very firmly to calvarium, more opaque than natural, cerebral vessels turgid; in the seventh, blood effused into arachnoid, fornix and edge of third ventricle soft, red, and tumid, brain softened. In the same fourteen cases, the spinal column was not opened in six:* of the remaining eight, the cord and its membranes were quite healthy in three, and only a little congested in one; and of the four others, the particulars are these:—in the first, soft adhesions of the arachnoid, grey matter dark; in the second, vessels rather large and numerous, serous surfaces opaque, old adhesions of the membranes, especially posteriorly; in the third, medulla slightly softened, rachidian fluid opaque, yellow, and densely coagulable by heat; in the fourth, softening of the cord opposite the fourth and fifth dorsal vertebrae. These facts, then, go to show that structural disease of the great nervous centres is no necessary accompaniment of chorea, and also that no one centre is affected exclusively when such disease is present, and, doing this, they justify the statement already made that morbid anatomy does not do much to connect chorea with a definite organic lesion in a particular part of the nervous system.

The part which inflammation or fever has to play in the production of chorea is a point upon which it is necessary to have a very clear view, for of all the questions connected with the pathology of chorea this is of most importance practically: and here fortunately there is no great difficulty in arriving at a decision.

* My friend and colleague, Dr. Hughlings Jackson, believes that the corpus striatum and the convolutions near this body are especially at fault in chorea, and that plugging of the minute vessels supplying the corpus striatum is the immediate cause of the disease, and the opinion of so careful and clever an observer is very deserving of attention, but as yet the clinical facts are wanting which are necessary to give the theory a firm foundation.
At first sight it may be supposed that the pathological facts which have been given favour the idea that inflammation of the brain or spinal cord, one or both, has to do with the production of chorea; but a moment's reflection is sufficient to dispose of this supposition. It is plain, in fact, that this inflammation cannot be regarded as essential to the chorea, for in some of the cases there are no traces of inflammation. This inference is inevitable. Moreover, the clinical history of these very inflammations, apart from chorea, leads to the same conclusion, for the symptoms of these inflammations are not those of chorea. There are also on record many cases in which inflammation in other parts, as in the lungs, has been developed in the course of chorea, and in which the choreic symptoms have been suspended during the inflammation. The case, indeed, is one which seems to justify the inference that the chorea is connected, not with inflammation, but with a state which may issue in inflammation. The case is one in which all seems to be explained if it be supposed that the chorea is connected with irritation, not with inflammation—with the state, that is to say, which precedes inflammation always, and which may or may not issue in inflammation. In this way, then, the cases which have been given, in which the traces of inflammation are absent after death, must be looked upon as cases in which the chorea proved fatal before irritation issued in inflammation, and the cases in which the signs of inflammation were present, as cases in which before death the irritation had issued in inflammation. Nor is there anything contradictory to this conclusion in the clinical history of the cases of which the post-mortem appearances were those of inflammation, for there is nothing in this history to show that this inflammation may not have occurred very shortly before death, and that the true choreic symptoms may not have disappeared as the true symptoms of inflammation made their appearance.

And, certainly, there is little reason for connecting chorea with fever. On the contrary, there appear to be good grounds for believing that the maxim of Hippocrates holds good here as in other cases—febris accedens solvit spasmos. At any rate, there are many cases on record of measles, scarlet fever, rheumatic fever, or some other fever, being developed during the course of chorea, and in which the choreic symptoms have been suspended during the fever. I have met with seven such cases. Indeed, so far as I have had the opportunity of judging, the constant rule appears to be, that the chorea is aggravated in the initial stage of the fever—that is, in the cold stage, or stage of irritation, and suspended more or less completely when the stage of reaction, or hot stage, is established.

The history of chorea in relation to inflammation and fever, indeed, so far as I can see, would seem to be like that of disorders which are more or less akin to chorea—namely, tremor, convulsion, and spasm in their various forms. For what is this history? In an attack of common trembling, the circulation is greatly depressed, and the pulse does not recover itself until this paroxysm is over; and in paralysis agitans the
paleness and chilliness of the surface of the body, and the decided relief afforded by wine, tell a similar story. In delirium tremens the cold perspirations, the quick and fluttering pulse, the moist and creamy tongue, are all significant facts. The initial rigor of fever, moreover, is coincident with wanting warmth, miserable pulse, sunken countenance, blueness of nails, cutis anserina and other signs of vascular collapse, and subsultus goes along with the most utter prostration of the powers of the circulation. And in mercurial tremor, an inference as to the real state of the circulation may be drawn from the fact that the subjects of this disorder are not unfrequently in the habit of resorting to gin and other stimulants for the purpose of making themselves steady. There even appears to be something un congenial between tremor and an excited state of the circulation. The state of the circulation in the delirium, of which trembling is the distinctive feature—delirium tremens—is quite different to the state of the circulation in the delirium in which there is no trembling. In the latter case—in the delirium of acute meningitis, for example—the skin, especially the skin of the head, is hot and dry, not cold and damp; the pulse is hard and strong, not weak and fluttering; the tongue is parched and brown, not moist and creamy—the condition is one, in fact, of high fever, and not one which, as in delirium tremens, is more akin to collapse than to high fever. And it is not less certainly a fact, that delirium tremens loses its characteristic trembling if acute head-symptoms and high fever make their appearance in the course of the disorder. Moreover, it must be borne in mind, as pointing to the same conclusion, that the initial rigors of fever disappear pari passu with the establishment of the vascular reaction of the hot stage, and that they return in the form of subsultus when the state of reaction has died out, and the patient is left utterly prostrate and helpless. Again, there is reason to believe that spasm is associated frequently with a depressed state of circulation. During the attack of catalepsy, the appearance of the patient is very like that of a corpse, and it may even be necessary to apply the ear to the chest to know of a certainty that the heart continues to beat. In tetanus, as all are agreed, there is no fever, and in the tetanus arising from strychnia, as Dr. Harley has shown, one effect of the poison is to prevent the blood from becoming properly oxygenated. In cholera the cramps are coincident with a state of almost pulseless collapse. In hydrophobia, the condition of the circulation is as far removed from feverish excitement as in tetanus. And, certainly, a similar inference may be drawn with respect to the state of the circulation in cramp in the leg and elsewhere, for these seizures are met with, not in strong persons, but in those who are weakly, and especially in those who are elderly as well as weakly. Nay, there is reason to believe that spasm in its various forms is antagonized rather than favoured by an excited state of the circulation. In tetanus it appears to be the rule for the spasm to gain ground almost in exact proportion to the degree in which the pulse loses its true power. In hydrophobia it would seem as if the same law held good, for on analysing the histories of a consi-
derable number of cases, I find that there was less agitation, less convulsion, less spasm where the circulation was less depressed than it is in the ordinary run of cases. Nor is a different conclusion to be drawn from the history of spasm as it is set forth in whooping-cough. For what is the fact? The fact is simply this—that the whoop, which is the audible sign of the spasm, does not make its appearance until the febrile or catarrhal stage has passed off; that it disappears if pneumonia, bronchitis, or any other inflammation be developed in the course of the malady; and that it returns when the inflammation has departed. And most assuredly there is no clinical evidence to show that convulsion is associated with an over-active condition of the circulation. In the fevers of infancy and early childhood, especially in the exanthematous forms of these disorders, convulsion not unfrequently occupies the place which belongs to rigor in the fevers of youth and riper years. It occurs in the cold stage of the fever, when the powers of the circulation are greatly depressed in every way; and it is confined to this stage, except in those cases in which there are certain brain and kidney complications, when it may also take the place of subsultus, or rather of death itself, for when it occurs at this time the patient has all but ceased to strive in the "struggle called living." Nay, I am even disposed to think that there is something altogether un congenial between convulsion and the hot stage of the sympathetic fever connected with inflammation, for it is a fact not unfrequently verified, that fits of common epilepsy are often suspended for the time by causes which give rise to a state of sympathetic fever in the system. For example, I can call to mind four or five cases of epilepsy, in which high sympathetic fever was set up by a fracture or other injury inflicted during a fit, and in which fits, which were of daily occurrence before the accident, and which recurred with the same degree of frequency afterwards, were altogether suspended so long as the fever continued. Nor is a contrary conclusion to be deduced from the history of the convulsion connected with teething, with worms, or with any other condition in which what is called "morbid irritability" is the prominent characteristic, for it is found, not only that fever is almost entirely foreign to the state of "morbid irritability," but also that convulsion, when it does occur, is associated with seasons of decided vascular depression. In a word, the result of bedside study has been to convince me that the true place of convulsion, in connexion with any form of febrile disorder, is in the cold stage before the hot stage, or in the cold stage after the hot stage, and not in the hot stage itself; that, in fact, there is something un congenial between convulsion and an excited state of the circulation. And so also with ordinary epilepsy, the general history of the disorder appears to be that the convulsion is antagonized by an excited state of the circulation rather than favoured by it.

As it seems to me, then, there is nothing unintelligible in the fact that chorea, instead of being connected with a state of inflammation and fever, is connected with a state which must be looked upon as the
very opposite of inflammation and fever. As it seems to me, indeed, there is nothing in this part of the history of chorea but what was to be expected from the history of tremor, convulsion, and spasm in their various forms. Nay more, the antagonism between chorea and inflammation or fever is, as it seems to me, nothing but what is necessitated by the physiological as well as by the pathological history of muscular contraction. But these are topics upon which I may not dilate further in this place, and I therefore bring my remarks under the present head to a close, by simply saying, that those who care to know more of what I think on this subject, will find what they want in the lectures which I delivered at the Royal College of Physicians in London, now four years ago.*

Nothing can be more perplexing than the statements made by various authorities respecting the efficacy of remedial agents in the treatment of chorea. Few voices, it is true, are now raised in favour of the old-fashioned antiphlogistic ways of treatment in which blood-letting and purgatives and low diet figured so conspicuously; but beyond this all that is uttered seems to be dictated by the spirit of contradiction or scepticism. Indeed, so little unanimity of opinion is there respecting the treatment which ought to be pursued in chorea, that the only course is for each one to glance at the principal remedial agents recommended, to weigh the statements made respecting them as well as he can, and to take upon himself the responsibility of deciding upon his own course of action.

Sir Thomas Watson considers that the most suitable medicine in cases of chorea is, as a rule, some preparation of iron: and this verdict is accepted by the great majority of English practitioners in medicine. Dr. Elliotson says that he cured forty cases in succession by the use of full doses of sesquioxide of iron, the time spent in the cure varying from six to eight weeks. I have not used iron much in the treatment of chorea, and I have not seen it used to any great extent by others. Not unfrequently, however, I have known a person using this agent go on for a while with it, and then discontinue its use, apparently as if he were not satisfied that all the good was being done which ought to be done. Of the several preparations of iron which have been recommended, I am disposed to believe most in the syrup of the iodide, the use of which was first suggested by the late Dr. Barlow, of Guy's Hospital. I have certainly seen several cases in which the use of this preparation seemed to be followed by unequivocal evidence of improvement; but, on reflection, I find it difficult to refer this change for the better to the iron altogether, or even to the iron chiefly. On the contrary, I am disposed to think that the iodine is entitled to a fair share of the credit, to say the least; and that the iodine in the doses usually given, is stimulating or restorative in its action, rather than alterative, in the sense in which it is usually supposed to be alterative. I fancy, also, that there is a growing doubt

* Lectures on Epilepsy, Paralysis, Pain, and some other Diseases of the Nervous System. Post 8vo. (Churchill and Sons.) 1862.
as to the efficacy of iron in cases of chorea, and that many would now be disposed to agree with the late Dr. Hughes, who says only that iron has been administered in numbers of the cases of chorea recorded in his admirable report, and that it has “sometimes succeeded where zinc has failed.”

Zinc is given very largely in the treatment of chorea. In the cases of chorea occurring in Guy’s Hospital, the late Dr. Hughes says, that “zinc in the form of sulphate, has been the most frequently employed as a remedy, and has generally been most successful,” and forty-five cures out of sixty-three cases, or five in seven, are credited by him to this medicine. Dr. Barlow says, “In ordinary cases, the exhibition of purgatives to keep the bowels freely open, and the sulphate of zinc in doses, gradually increased from a grain to even fifteen or twenty grains, or even more, will effect a cure. When, however, the sulphate has been used in these large doses, its sudden discontinuance seems to be felt by the system, and a return of the symptoms ensues: the best rule, therefore, for its exhibition, is as follows: the bowels being kept open, the sulphate of zinc should be given in doses commencing with a grain three times a day, and in the case of a child about twelve years old, the quantity should be increased by the addition of a grain daily, until the medicine causes sickness, or there is an obvious diminution of the choreal movements. In the former case the dose should be diminished by at least one-half, and so continued for several days, with a view to establishing a tolerance; but if, on the other hand, there be a marked improvement, it should be no further increased, but continued without alteration until either the improvement ceases—in which case it should be again gradually increased—or the disease has altogether subsided. Whenever the latter is the case, we ought to diminish the dose day by day, rather than discontinue it suddenly, as by following the latter course we have less reason to dread a relapse.”

In continuation of these remarks Dr. Barlow adds, “In some cases, however, especially those in which there is considerable anaemia, the iron seems to have more control over the disease than has the zinc, though these cases are rather exceptionable ones.” The late Dr. Bright tells us that he found the sulphate of zinc answer where the carbonate of iron had failed, and that where iron succeeds, there the zinc had done no good: and Sir Thomas Watson, who repeats this statement of Dr. Bright, leaves us to infer that these words express his own experience in the matter.

Arsenic is another favourite medicine in the treatment of chorea, especially in Great Britain and Ireland. Thomas Marten was the first to recommend it, now sixty years ago, and since this time it has been very extensively used. Dr. Romberg, speaking of the various remedies recommended, and alone deserving confidence as capable of arresting the disease in a short space of time, says, “The foremost among those, an experience of several years has taught me, to be arsenic.” Dr. Begbie also writes, “In an experience of nearly thirty
years I have never known arsenic fail." Nor would it be at all difficult to cite other authorities to the same effect. Dr. Begbie gives five drops of Fowler's solution twice a day, an hour after a meal, and adds a drop to the dose every day, until the specific effects of the mineral upon the system are observable, and then he suspends the treatment for a while. He goes on with the medicine, that is to say, until he is warned to stop by itching and swelling of the eyelids, by redness of the conjunctiva, by a white silvery appearance of the tongue seldom accompanied by tenderness, and by nausea and uneasiness at the pit of the stomach. I have often used arsenic in the treatment of chorea, and I have great faith in its efficacy as a medicine in the malady. At the same time I have often abandoned its use, in consequence of the gastric disturbance which, do what one will to prevent it, was set up by it. It seemed, indeed, as if in these cases the stomach would not tolerate the medicine in doses large enough to produce a sufficiently rapid action in the cure of the disease. It did not follow, however, that this intolerance of the stomach was a sufficient reason for abandoning the arsenic in these cases, for the stomach is not the only channel by which this medicine could have been introduced into the system. Failing the stomach, indeed, the hypodermic or endermic method might have been tried, and that too, I have now reason to believe, with many chances of advantage to the patient. The case which suggested to me the hypodermic use of arsenic, was that of a patient in the Westminster Hospital (Hallett Ward), Margaret S. by name. This patient had suffered for nine years from a distressing choreal affection of certain muscles of the neck, by which the head was kept continually turning and bobbing. At different times various modes of treatment had been tried, including the hypodermic injection of morphia and atropine, without the least benefit. When first admitted under my care, and for the three weeks following, I gave her bromide of potassium and morphia, my chief object being to procure sleep and alleviate pain in the neck; for the muscles in the neck, which were the seat of the morbid movements, were very tender in many places, and the movements themselves attended with much pain; but harm, rather than good, seemed to be done by these means. The idea of injecting arsenic hypodermically occurred to me on the 12th of January, 1866, and was carried out on the same day. Fowler's solution was chosen, and the part selected was the most tender point over the contracting muscle. Three minims were injected on the 12th, m v. on the 15th and on the 17th, m vij. on the 19th, m viij. on the 22d, m viij. on the 25th, and again on the 29th, m viij. on February 1st, m ix. on the 3d, m x. on the 6th, m xj. on the 8th, m xij. on March 1st, and again on the 10th, m xiiij. on the 12th, m xiv. on the 14th. On the 21st the patient left the hospital almost well. Before the fourth injection was practised a marked change for the better had taken place; before the eighth, the choreal movements were almost at an end, and the change for the better had gone on steadily progressing from the beginning. Between the eighth and the ninth injection there was an interval of.
three weeks*—the injections being suspended on account of the local irritation and inflammation which they had set up. When the patient left the hospital there was some stiffness in the muscles which had been the seat of the disturbance, by which the head was slightly twisted, and the voluntary movements of these muscles were not free; but every day there was a change for the better in these respects. In the hospital, the only treatment associated with the injections was a gymnastic one, the patient being made to move her head from side to side, and backwards and forwards, in time with a slowly-moving pendulum, together with an occasional dose of morphia at bed-time, this drug being given less on account of the malady in the neck, though pain in this region was still complained of at night, than on account of a distressing habit of sleeplessness. Two months have now elapsed since the patient left the hospital. She occasionally presents herself for inspection, and her state continues very much the same as it was, just one step from being quite well, and not bad enough to make her wish to have the injections repeated. She goes on exercising the muscles of the neck with the pendulum, and having them shampooed, and for medicine she has now and then had some cod-liver oil. In this case, and in those to which I am about to refer, the object in introducing the arsenic hypodermically, was, not to escape gastric irritation, but to produce some local change in the nerves of the parts which were the seat of the disorder, as well as to bring about some more general change in the system. I have also a second case, not unlike that which I have just given, which promises to be equally fortunate. This is that of a lady, aged sixty, who for ten years had suffered, in a very distressing manner, from constant automatic movements of certain muscles of the neck, by which the head was kept continually twisting to the left shoulder. This lady had been under my own observation for six years, and during this time I had tried everything I could think of without the least good. The arsenical injections were begun six weeks ago; fifteen of them have been practised in this time, and the improvement produced by them is such that the patient will remain in town, greatly to her own inconvenience, in order to go on with them. In this case, the injections have produced far less irritation than in the first. I may also add, that I have employed, with results more or less satisfactory, the hypodermic injection of arsenic in certain cases of neuralgia, epilepsy, and other affections of the nervous system, and thus the two cases which I have given are not the only cases which furnish to my mind reason for believing that this mode of treatment may be of use in the treatment of certain cases of chorea. I have also used arsenic endermically as well as hypodermically in two cases of chorea. In order to this

* Up to the eighth injection undiluted Fowler's solution was used; when the injections were resumed, and after this time, this solution was diluted with an equal quantity of water. In other cases, also, where the same mode of treatment has been carried out; I have employed a mixture of equal parts of this solution and water, for I found that the solution diluted to this extent produced very much less local irritation than the undiluted Fowler's solution.
I have dropped from fifteen to twenty drops of Fowler's solution upon lint moistened with water, and applied this, under oil silk, night and morning, to a raw blistered surface. This application gives rise to considerable local irritation; indeed, it generally, before the week is over, has the effect of covering the blistered surface with a thin, dry eschar, and of causing a zone of angry pimples to crop up in the skin immediately surrounding the part which has been blistered. Owing to this irritation, indeed, it is generally necessary to make pauses in the treatment after going on for six or seven days at a time. As yet, however, I have little practical experience of the effects of this mode of treatment in actual cases of chorea. I have tried it in two cases of average severity, in one of which the patient was well in twenty-eight days, in the other in thirty-two days; and this is all that I can say respecting it except this, that, as with the hypodermic method before mentioned, so also with this, I have given it a trial in certain cases of neuralgia, and epilepsy, and that the results arrived at in these cases lead me to hope that this mode of giving arsenic may prove to be a not unimportant addition to the armamenta therapeutica. With respect to the comparative merits of the hypodermic and endermic methods of introducing arsenic into the system I cannot yet speak. I incline to give the preference to the former method, both as least distressing to the patient and as most efficacious; but I have, as yet, no sufficient practical experience to justify the expression of a definite opinion. I allow, moreover, that I may be prejudiced in favour of the hypodermic method by the remembrance of the cases which I have given; and no wonder, perhaps, for the first case, so far as I know, is the first of the kind in which unequivocal good has been done by any kind of medical treatment.

During the last twenty-five years strychnia has been employed somewhat extensively in the treatment of chorea, especially in France. Dr. Trousseau was the first, or among the first, to do this, and after an experience of a quarter of a century, he is still disposed to give the preference to this practice. The preparation employed by this physician is a syrup of the sulphate of strychnia, made by dissolving 3 grains of the sulphate in 3x of simple syrup; and the manner of giving it, which is peculiar, is as follows:—In children from five to ten years of age, the treatment is commenced by giving a teaspoonful of this syrup (containing 1/4th of a grain) twice or thrice a day—one dose in the morning, another in the evening, and the third, if there be a third, at noon. On the next day these doses are repeated. On the following days, each day an additional teaspoonful of the syrup is given until six teaspoonfuls are given, care being taken to distribute these four, five, or six doses at equal intervals through the day. Having arrived at this point, if the physiological effects of the dosing are not yet produced, dessertspoonful doses are substituted for teaspoonful, and the same rule is observed with these larger doses as with the smaller. Beginning with two or three dessertspoonfuls in the course of the day, and giving three on the next day also, the doses are increased by a
dessertspoonful each day, until six dessertspoonfuls are taken in the course of the day, care as before being taken to distribute these doses, few or many, with intervals between them as wide as possible. If the desired effect be not yet produced, a still bolder practice is pursued, and a tablespoonful of the syrup is substituted for one of the dessertspoonfuls; and you are to go on, still augmenting, but in a way which is not very clearly laid down:—"En augmentant progressivement," M. Trousseau says, "avec la même prudence, avec la précaution essentielle de distribuer le médicament à des intervalles sensiblement égaux dans le courant de la journée, vous arrivez à donner aux enfants de cinq à six ans, 50, 60, 80 et jusqu'à 120 grammes [5 grammes go to the teaspoonful] 25 milligrammes de sirop; 3, 4, jusqu'à 6 centigrammes de sulfate de strychnia." In persons older than ten years, Dr. Trousseau begins with large doses, with dessertspoonfuls in place of teaspoonfuls, and goes on until he reaches 200 grammes of the syrup—a quantity containing no less than 10 centigrammes, or 1½ grains of the active principle. The object is to produce the full physiological effects of strychnia, and to maintain them for a while, and the duration of the treatment is said to be thirty-three days for girls, and seventy-four days for boys. When the medicine begins to tell upon the system, the symptoms are, twenty minutes after taking it, or thereabouts, slight stiffness in the jaw or neck, some headache, confusion of sight, and giddiness, and some disagreeable "démangeaisons" in the parts of the skin covered with hair. Afterwards, as the system becomes more deeply impressed, the stiffness extends from the jaw and neck to the limbs and elsewhere, especially to the limbs most affected with chorea, which limbs are also in all probability more or less paralysed, the itching of the skin is no longer confined to the hairy parts, and painful jerks or shocks, or still more obvious tetanic symptoms, make their appearance. The tolerance of strychnine varies not only in different individuals, but in the same individual at different times, so that the dose which was not more than enough one day, may be poisonous the next. In fact, the treatment is one which requires to be most carefully watched, and which cannot well be watched with comfort, especially by the friends of the patient, however enlightened or forewarned they may be.

Another heroic treatment for chorea, which has found some favour in France, is that by tartar emetic. Laennec has left on record three cases of chorea treated by large doses of this medicine, and others have tried the same method with results, as they seem to think, more or less satisfactory, especially MM. Boulay, Gillette, and Henri Roger. M. Gillette's method, which is that adopted by M. Roger, is to give the antimony for three days, to withhold it for three or five days, and again to give and withhold it for the same period, as often as may be necessary, if the symptoms have not yielded to the medication of the first three days. On the first day of the first triple series of days, the dose given in the twenty-four hours is from 20 to 25 centigrammes (1 centigramme is = ′15, or nearly ⅗th of a grain). This
dose is doubled on the next day, and triped on the third day; then the patient is allowed to rest from three to five days. On beginning again, if this be necessary, the dose given on the first of the three days, which is to be doubled on the next day, and triped on the day following, is 5 centigrammes larger than that used on the day in which the treatment was commenced. If this be not enough, after waiting again for from three to five days, the dose for the first of the three days is 5 centigrammes larger than that used on the first of the last series of three days, for the second day the dose is doubled, and for the third day the dose is triped; so that, if the dose given on the first of these three days was 30 centigrammes, the dose on the last of these three will be 90 centigrammes, or nearly 14 grains! In the majority of cases, we are told, the first doses are followed by nausea and vomiting of a glairy matter, but these soon pass off, and complete tolerance is established, especially if care be taken to withhold as much as possible all dietetic drinks. We are told also that diarrhoea is uncommon, that constipation is not uncommon, that the pulse becomes slower, that the skin moistens, and that the general health improves. Indeed, Dr. Bourguignon, speaking of certain children, patients of M. Gillette, under this mode of treatment in the Hôpital des Enfants Malades, at Paris, says:—"Les enfants ne sont nullement abattus, ils conservent leur gaieté." Dr. Bourguignon, who is strongly in favour of this treatment, tells us also that in ten cases—whether in M. Gillette’s practice, or in his own, he does not say—the patients got well in sixteen days, as an average, the shortest time being four days, the longest, twenty-four.

Iodide of Potassium is another remedy which has been tried somewhat extensively in the treatment of chorea, and to a less extent so has bromide of potassium. This iodide was supposed to be indicated by the probable existence of a rheumatic or lymphatic predisposition in the patient, or by the actual presence of some meningeal irritation or inflammation, and these indications have been carried out fully and frequently, but the practical results of this treatment, so far as I know, are unsatisfactory. Nor is a different opinion to be expressed with respect to the bromide. I have tried this medicine in several cases, and tried it fully, and from what I knew of its strange efficacy in epilepsy, I was strongly prejudiced in its favour; but the result, as I have said, is that the bromide appears to be no more justly deserving of confidence than the iodide.

As might be expected, opium is a medicine which has not been overlooked in the cases in question, especially in the severer cases. As in tetanus, there appears to be a remarkable tolerance of this medicine in chorea, and in several cases enormous doses have been given; indeed, in any case it appears to be necessary to give large doses, in order to procure what may be supposed to be the object in view, that is, sleep. I have seen opium employed in five very severe cases of chorea, largely, and from what I saw in these cases, I am not wishful to see the experiment repeated. I am speaking now of the free use of opium by itself, and not of opium in moderate dose
along with other agents, with the free use of alcoholic stimulants especially. This, I believe, is quite a different matter. Nor does there appear to be sufficient reason for supposing that other narcotics, not excepting cannabis indica, are more to be trusted than opium in cases of chorea.

The inhalation of chloroform or ether has been had recourse to in many severe cases of chorea. I have seen three such cases in which chloroform was used in this way, and my impression was that harm not good was the result. I believe, also, that harm rather than good is likely to be done in these cases, unless alcohol is given in sufficient quantities before the inhalation. If this be done the patient may remain asleep for some time, and awake the better; if this be not done, there is great danger, so far as my experience of the use of chloroform inhalations is concerned, of the patient waking almost immediately and of being more unnerved and more agitated than he was before he was put to sleep. At the present time I am in attendance upon a case of chorea, attended with much sleeplessness, until the practice was adopted of giving at bed-time a few whiffs of chloroform after a glass of hot negus. The chloroform had been tried for four nights without the negus, and harm rather than good had been the result. It has now been tried with the negus for a week, and, as it would seem, with unmistakeable advantage. Nor is this an isolated case.

Antispasmodics, such as camphor, ether, valerian, assafetida, and musk have been tried extensively, and the general verdict appears to be that they are not useless. I am disposed to place considerable confidence in camphor and also in ether, in camphor especially. I now give very generally this last-named medicine dissolved in cod-liver oil, and my impression, from what I have seen, is that this addition to the oil is a decided advantage to the patient.

Turpentine has been given for various reasons in chorea—as an anthelmintic and purgative chiefly. At one time I gave it rather as a general stimulant, and, as it seemed, with benefit to the patient. I then tried mineral naphtha with the same view, and came to the conclusion that this medicine was more pleasant than turpentine, less trying to the system, and not less efficacious. During the last six or eight years, however, I have rarely given either one or the other of these medicines, and one chief reason for this seems to be that I have gradually come to prefer the treatment, of which I have to speak in a few moments.

Ammonia is also a remedy which has some good claim to be mentioned in the present place. I have tried the sesquicarbonate in several cases, singly and in combination, and the trial has been to my mind eminently satisfactory. I am, for example, at present, seeing a little choreic boy, who had been for three weeks treated, without any benefit, with sulphate of zinc, and who has wonderfully improved during the last three days, by leaving off the zinc, and by substituting sesquicarbonate of ammonia in five grain doses every three hours. In other respects there was no change in the treatment, and the patient
is too young to allow it to be supposed that he was affected beneficially by the change of the practitioner.

For various reasons, theoretical and practical, the free use of alcoholic drinks has long seemed to me to be the foundation of a rational plan of treatment in chorea, and the larger experience of the last few years has only served to confirm me in this opinion. I have seen enough to know that, as a rule, the change for the better is unmistakeable when, after the carrying out of a contrary mode of practice, alcoholic drinks are given with a liberal hand. I have notes of three cases of great severity, where rapid amendment was brought about by giving at frequent intervals, an egg beaten up with a large glass of sherry or with an equivalent dose of brandy, and I verily believe that this plan would rarely fail if carried out in time—if carried out, that is to say, before the nervous system had become thoroughly exhausted and broken down, as it does do in the end. Indeed, in a bad case, where a dangerous degree of sleeplessness had to be dealt with, there is nothing in which I should have more confidence than in the free use of alcoholic drinks. I should look upon these means properly, that is freely, used, as the natural means of procuring sleep and all the beneficial consequences of sleep. I should be afraid of attempting to attain the same end by the use of medicines more or less analogous to alcohol in their action, because these medicines would all of them be more likely to disturb the action of the stomach and so interfere with the restoration of the system by food. Nay, for the same reason I should even be almost afraid of giving small doses of opium with the view of conciliating sleep, though I have no doubt that the proper dose of this drug at the proper time, in conjunction with the proper dose of alcohol, might be very satisfactory practice. In a word, I cannot but think that it is a perfectly rational way of dealing with severe cases of chorea to push alcoholic drinks until they produce drowsiness—until, that is to say, they exercise a decidedly sedative action upon the system. At any rate I have carried out this idea in more than one case of the kind with what seem to me to be very satisfactory results.

In bad cases of chorea, as a matter of course, the recumbent position is a necessary part of the treatment: and in cases of ordinary severity, my own impression is that the patient would improve more rapidly if he were kept longer in bed. Indeed, it surely stands to reason that rest, properly used, is a right means of remedying a state of muscular disorder, in which muscular fatigue is an unmistakeable element. Nay, it is not too much to imagine, that the persistency of many cases of chorea may be not a little owing to the patient being allowed to be up and fidgeting about when he ought to be in bed.

Exercise, on the other hand, properly used, cannot well be dispensed with as a means of treatment in chorea. In ordinary cases, indeed, it is difficult to overrate the importance of suitable gymnastics as a means of cure. This is no new idea. Darwin insisted upon it long ago; and from what has been done in this direction since his time,
especially by Ling and his successors in the practice of the so-called "movement-cure," it is perhaps not too much to say that chorea may be one of the consequences of neglecting gymnastics as a means of education in children. Certain it is, that ordinary cases of chorea get better rapidly—the average duration of the period of treatment being sixty days, under a properly arranged course of gymnastics, with little or nothing else. The practice of M. Sée, at the Hôpital des Enfants Malades in Paris, may be cited in support of this statement; and it would not now be difficult to find corroborative passages in the practice of others. For myself, I should think that I was omitting an important duty if I did not prescribe the use of some suitable exercise for a patient suffering from chorea—the use of a skipping-robe, or trapèze, if nothing else. Dancing has long been a favourite idea with me as a means of exercise in cases like these; and so have calisthenics regulated by music. More than one choreic patient I have known to be cured by learning to dance, and I think that music might be employed with advantage now, as it was in the case of the tarantula dance of old, in quieting severe cases of chorea, anomalous or not. Indeed, there is more than one case on record in which music has been so employed. It may be supposed also that music will help the choreic patient in his gymnastic efforts in the same sense as that in which it nerves the acrobat to the performance of his wonderful feats. In a word, it is not necessary to think long before it must become self-evident that orderly movements, be they those of dancing, calisthenics, or more special gymnastics, and be they regulated by music or not, are natural remedies for disorderly movements such as are met with in ordinary cases of chorea, and that a very important means of cure is neglected if they are not provided. Indeed it is to be hoped that the time is not far distant when a suitable gymnasium will be considered as much a part of the proper fittings of a hospital as the dispensary, and when medical men more generally will be alive to the importance of suitable gymnastics, not only as an educational, but also as a curative measure. Surely there is a lesson to be learnt from the results of the carrying out of the "movement cure."—a lesson which the practitioners of orthodox medicine are not justified in continuing to decline to learn because it happens to have heterodox belongings!

Baths, of one kind or another, have been extensively employed in the treatment of chorea. In this country the cold shower bath has been the favourite mode of bathing, and there are some good grounds for this preference. Part of the good results is ascribed to the shock; part—a greater part, perhaps—to the reaction. Still there are, unquestionably, many cases in which the shock is not tolerated, and where reaction is not easily established—cases in which the patient is rendered worse rather than better, so far as the chorea is concerned, with the additional disadvantage of a bad cold, or actual rheumatism, or some other evil. And these latter cases are by no means uncommon. Nay, it may even be suspected that all cases would come into this category if care were not exercised more or less. The same
CHOREA.

141

remarks apply also to cold plunge baths, and to other forms of cold baths. With respect to hot baths and to warm baths, the case is very different. A hot bath at bed-time has often seemed to me to have a marked calming influence. I am also disposed to think that a good part of the benefit ascribed by M. BaudeLocque to sulphur baths (each bath contains about four ounces of sulphuret of potassium) is to be ascribed to the high temperature of the water, or, at any rate, to this in conjunction with the counter-irritation set up by the action of the sulphuret upon the skin. The fact appears to be that baths of one kind or other are not sufficiently recognised as a means of cure, not only in chorea, but in many other cases of disease, by the orthodox practitioners of medicine. With baths, indeed, it is very much as it is with "movements" as a means of cure, and hydropathy, like kinesitherapy, has a lesson to teach, which medical men ought to set themselves to learn if they would be fully provided with the means by which to contend successfully against disease.

Electricity is another agent, which requires a passing mention in this place, though all that can be said respecting it is, that as yet there appears to be little or no reason for placing any confidence in it as a means of treatment. Whether this will be always the case—whether there are not modes of using electricity which will have the effect of quieting choreic and analogous movements (so long, at any rate, as they are used) remains to be seen. I suspect that there are such modes, and that they will be beneficial, and that too not a little, in the case in question, but I have not yet the facts to justify the expression of a belief on the subject.

For the last seven years I have employed cod-liver oil in many cases of chorea, and, so far as I can judge, I have good reason to be satisfied with the results. In adopting this practice my main object was to restore nerve-tone by improving the nutrition of nerve-tissue. I remembered that fatty matter was an essential ingredient in nerve-tissue; and, remembering this, I came easily to the conclusion that one natural way of attaining to the end in view was to take care that the food contained a sufficient amount of fatty and oily matter. Without a due supply of these matters, I reasoned, the nerve-tissue must be of necessity starved—that, in fact, to withhold these matters, or to supply them in insufficient quantity, would be as great a mistake in cases where the object was to improve the nutrition of the nerves, as it would be to withhold lean meat in cases where the object was to get more muscle. I argued in this manner, and be the theory right or wrong, I think, as I have said, I have no reason to be dissatisfied with the results of putting it in practice.

For the last seven years also I have used phosphorus in the majority of cases of chorea in which I have used cod-liver oil, and for the same reason. I asked myself whether the fact that phosphorus is present in large quantity in the great nerve-centres, and that the amount of this ingredient seems to have some direct relation to the activity of the nervous functions, being as much as 2 per cent, in
adult life, and below 1 per cent. in infants and idiots, might not show that phosphorus is specially indicated as food for a weak nervous system—as much indicated, perhaps, as iron in cases where there is a deficiency of red-corpuscles in the blood—and this question once put seemed to require an answer in the affirmative. "In small doses," says Dr. Pereira, "phosphorus excites the nervous, vascular, and excretory organs. It creates an agreeable feeling of warmth in the epigastrium, increases the fulness and frequency of the pulse, augments the heat of the skin, heightens the mental activity and the muscular powers, and operates as a powerful sudorific and diuretic." In large doses, without doubt, phosphorus is a caustic poison; in proper doses, it produces the very changes which are to be desired in cases of chorea and analogous forms of convulsive disorder. In proper doses, and properly watched, it is quite innocent in its action, and may be very beneficial. Of this I am confident. The forms in which I first gave phosphorus in chorea were the phosphorated oil of the Prussian Pharmacopœa and the ethereal tincture of the French Codex (forms containing 4 grains of phosphorus in the fluid ounce), but lately I have preferred the hypophosphites, especially the hypophosphate of soda, for the simple reason that these salts, which were originally recommended by Dr. Churchill of Paris as specifics in phthisis, are infinitely less nauseous than the oil or tincture, and not less efficacious. I have given for some time from 5 to 8 grains, three times a day, of the hypophosphate of soda to children, in cases of chorea, without any harm certainly, and, as I think, with unmistakable benefit, and I have not yet found any reason to change this practice for another.

In an ordinary case of chorea, the plan of treatment which I have now adopted as a rule for some time, is to give cod-liver oil in conjunction with hypophosphate of soda, making the draught containing the latter salt the vehicle for the administration of the cod-liver oil. With these medicines, according to circumstances, I have associated camphor or ammonia, one or both, adding the sesquicarbonate of ammonia to the draught containing the hypophosphite, and dissolving the camphor in the cod-liver oil. I have found that this latter solution is an excellent way of giving the camphor, and also that the camphor masks the taste of the oil not a little, and makes the stomach more tolerant of it. I have not kept notes of all the cases which I have treated in this manner, but I think I am quite within bounds when I say that the number now amounts to upwards of thirty, and that the average duration of the treatment was under three weeks.

I may also add that I have in three or four cases given arsenic along with hypophosphite of soda and cod-liver oil, and that the result, to say the least, was not such as to discourage a continuance of the practice.

If there be any special sources of irritation, as worms or carious teeth, these of course must be met and dealt with. If the agitation be
so great that there is danger of the skin being excoriated, or of the patient falling out of bed, properly padded sides must be fixed to the bedstead, or it may be expedient to encase the body and limbs of the patient in cotton-wool. If the affection be confined to certain muscles of the neck or elsewhere, it may be expedient to use hypodermic injections of arsenic, as in the cases related in the text, to divide a nerve, as has just been done by Mr. Campbell De Morgan, or to use the actual cautery. If there be a morbid mental condition, as there too often is, moral means of treatment must not be neglected. In fact, each case of chorea must be looked upon from a special as well as from a general point of view, and the success of the treatment will, in many instances if not in all, depend upon the skill with which special means can be combined with those general means of which I have spoken, and upon which I have dilated at greater length than I ought to have done.
VERTIGO.

By J. Spence Ramskill, M.D.

DEFINITION.—The sensation of moving, or the appearance of moving objects, without any real existence of movement.

DESCRIPTION.—Vertigo may present two forms: in the one the patient complains of giddiness in himself, external objects remaining stationary; in the other external objects assume various abnormal positions: for example, articles of furniture in the room, or patterns of paper on a wall, seem to chase each other round the apartment; or, in rarer cases, the vehicles in the street appear upside down, or the pavement undulates, or feels elastic. On attempting to walk, the patient may feel himself drawn or impelled forwards, sideways, or backwards, and he can only prevent himself obeying the impulse of a strong effort of volition. Minor degrees of disturbed balance, and the commonest sense of uncertainty of gait demand the same exercise of volition, for there is in all cases a perpetual fear of falling down or of rude contact against other persons or against surrounding objects. In slight cases Vertigo occurs only on movement; in severe ones, when at rest also, and even during sleep.

With both forms of vertigo we occasionally find perversions of the special senses. Patients complain of mistiness of vision, of being unable to see more than half an object, or of one half being out of all proportion to the other half, of exaggeration in size of an object, of deafness, or of hyperesthesia of the sense of hearing, the noise of passing vehicles assuming the intensity of thunder, or of metaesthesia or a perverted sense, ordinary loud sounds appearing clear, but soft and distant. In a distinct variety of Vertigo there is real deafness of one or both ears.

Associated with these functional disorders there are complaints of tinnitus aurium, a noise of pumping water, of intermittent pulsations of fluids, of the hissing of a tea-kettle, of the noise of machinery, in fact of many kinds of noises which defy and escape description; most commonly the noises are permanent, although they may vary in intensity whilst the Vertigo is intermittent, yet the noises are loudest during the vertiginous attack.
Prognosis.—It may be taken as a rule that in Vertigo unconnected with visceral disease, and in persons under the age of fifty, there is not much danger to life, nor from what is most usually dreaded, viz. paralysis. Sudden and violent attacks of an intermittent character are unusually eccentric in origin, whereas a constant sense of uncertainty in movement, and a susceptibility to the induction of giddiness from the movement of passing objects, especially if combined with a cloudiness of intelligence, or rather a want of the usual clearness, indicates usually a centric disturbance. When, however, a severe attack occurs, without any palpable cause, to a person after the climacteric has been reached, a cautious prognosis must be given, and the more so if it be associated with vomiting, or constant nausea, tingling of extremities, the sense of pins and needles in one hand or foot, or of neuralgia of a group of muscles, or of those of one limb. The just fear in such a case is the fear of impending apoplexy. A discovery of dilated heart, of valvular disease of that organ, of degeneration of kidneys, with the presence of albumen in the urine, will make the prognosis more serious still. Organic disease apart, Vertigo has been known to exist during a long life, and indeed, unless some other suggestive symptoms are superadded, it cannot be considered a dangerous disease. In fact, the longer the complaint has existed in any given case, the less dangerous it appears to be.

Etiology.—The direct proximate cause of all Vertigo appears to be a disordered cerebral circulation; whereby, on the one hand, the special senses convey a false impression to the sensorium, or, on the other, a faulty co-ordination of muscular action is induced.

Of remote causes it seems probable that any acute disease, or any sudden perversion of function of any important viscus on the body, may cause Vertigo, either directly or by reflex action. Thus we find stomachal vertigo as the commonest of all forms of the complaint, excepting only the invasion of all, or almost all, acute inflammatory diseases, the exanthemata, &c.; next, poisoning of blood, whether by disease, as from cachexia, excessive smoking, intoxication, or paludal poison; then organic disease of heart, of right or left side, after such disease has reached a certain point, which acts by altering the cerebral circulation in a twofold manner. In like manner the suppression of a long accustomed hæmorrhage acts, whether it be in the form of epistaxis, bleeding from hæmorrhoids, or prolapsus ani, or from the menstrual flow ceasing too suddenly.

The rapid suppression of an extensive chronic cutaneous eruption is an acknowledged common cause, and it is explicable on the same principle.

Varieties.—The varieties of Vertigo may be practically divided into eccentric forms, or those arising from functional disorder of any viscus or viscera in the body; or centric, from organic disease in the brain itself; or by blood-poisoning. There is a third variety, important
enough to demand separation from these groups. I have called it essential vertigo. It is not associated with any other head symptoms, and there is no appearance of depraved general nutrition. It occurs mostly in persons about thirty years of age, and is a rare form of the disease, as compared with Vertigo arising from other demonstrable eccentric causes. In other respects, a patient suffering from it will declare himself in perfect health. In all the cases I have seen, the complaint has been associated with a decidedly weak heart, a feeble small pulse, and with symptoms I take to indicate a dilated right ventricle. Another characteristic may be said to be this, that it is not materially improved by remedies, unless these are accompanied by rest and freedom from anxiety of every kind.

STOMACHAL VERTIGO.—The most common and most tractable eccentric variety arises from disorder of stomach, or of functional derangement of the liver and upper part of the alimentary canal. It often occurs suddenly in the middle of the night, or without any warning at any period of the day, and in a state of apparent robust health. From its violence it suggests the idea of imminent danger. The following case may be taken as a type:—A merchant, some three hours after breakfast, after transacting some business of an exciting character, was quietly walking from a neighbouring office to his own, when he was suddenly seized with violent Vertigo. He reeled, and immediately laid hold of an adjacent gas pillar; he felt sick. Resting a few minutes, he felt the giddiness subsiding, and tried to walk; but with the first step the Vertigo returned in greater violence, accompanied by a strange tightness of scalp. He asked a passer-by to assist him, and with the aid of this second person managed, reeling or rolling, to reach his office, a distance of a few hundred yards. Seated in his chair, the symptoms gradually subsided; and in a few hours, after a free evacuation of the bowels, he was free from the Vertigo, but he felt weak and shaken, and complained of a heavy diffused headache. From a very careful examination these facts were elicited. The Vertigo seemed to be of both forms described at p. 144. He felt giddy in himself, and his legs were feeble, but the objects in the streets were also strange. The shop windows seemed moving forwards, passers-by were racing after each other, the ground felt to his feet uneven, billowy, as if elevated and depressed, and he felt constrained to lift his feet over the apparent elevations. Yet he was distinctly conscious of this illusion, and tried to conceal it. The headache occupied the entire head; it was not acute; it gave the sensation of weight rather than of pain; it was not more frontal than vertical and occipital in its seat. There was no discoverable disorder of stomach, or of any individual viscus and, beyond the sudden attack of diarrhœa, nothing to suggest disorder of the abdominal viscera. He attributed the attack, and probably correctly, to having eaten very heartily a breakfast of which sausages and Devonshire cream formed a part, and to a hasty and very imperfect habit of mastication. During the ensuing month this patient had five separate attacks of the same
VERTIGO.

147

violence, but without the same disturbance of bowels, and without being able to discover any cause, most assuredly not in the matter of diet, in which he had become exceedingly careful. Yet he was completely and permanently cured by the remedies adopted for stomachal vertigo. As a matter of fact, it is very rare to find any positive signs of stomach disorder in these cases. They are named stomachal, because remedies addressed to the stomach cure, and cure readily and quickly. With respect to the kind of Vertigo experienced, it does not, exclusively, take either of the two forms; it assumes both characters in some individuals. However, it is often so entirely connected with the appearance of external objects to the patient’s eye, that the internal sense of giddiness is with difficulty made manifest. Curiously enough, it is rarely patients complain of exaltation or defect of hearing, or of tinnitus aurium, although both these complaints are very common in the chronic stomachal forms of Vertigo. The rationale of the symptoms would appear to stand thus:—Digestion progresses satisfactorily up to a certain point, when, owing to some temporary cerebral excitement, perhaps of transacting business, or of deep thought, the process is suspended, an irritation is conveyed to the blood-vessels of the brain, via the splanchnic or pneumogastric nerves, and a disorder of circulation and of brain nutrition follows, with a corresponding disorder of function of the particular parts of the brain affected. Like causes produce like effects, and, moreover, in disorders of the nervous system it seems that a perversion of function, once induced, is easily re-induced, and by slighter causes. Hence it is not surprising that, if a patient has suffered from this acute stomachal form of Vertigo once, he will be subject to recurrent attacks.

Chronic stomachal vertigo is of very common occurrence, and one often supposed to indicate the commencement of congestion, of organic disease of brain, of minute tissue change, premonitory of softening, or of threatening apoplexy; and the treatment which has been adopted under such erroneous diagnosis has only served to render the Vertigo permanent. Patients in this form of disease do not usually complain of the usual symptoms of dyspepsia. There is never any acute pain referred to the stomach after food; often, however, there is a slight weight, a somewhat tender epigastrium, only however felt on deep pressure, evidences not so much of a perverted as of a slow digestion. Complaints are sometimes made of a pain radiating from the stomach to the back, to the cardiac region, or of a general undefined uneasiness about the entire epigastric region. Rarely can more than this be made out by a most careful cross-examination of the patient’s stomachal symptom. In the lower ranks of life, however, such as we find in hospital practice, we meet with all sorts of complications; but that the symptoms appertaining to the stomach are not urgent, may be inferred from the fact that patients do not seek advice for their relief, but for the Vertigo, and some steadfastly refused to admit there could be any disorder of the stomach, when remedies addressed to that organ afterwards cured the Vertigo. Additional symptoms of functional disease
of other organs are, of course, in such a class of patients common, but they are found to be independent of, and had little influence on, the Vertigo.

A very usual combination of symptoms runs thus:—Vertigo, pyrosis, leucorrhcea. Vertigo, menorrhagia, leucorrhcea, anorexia. Vertigo, weight of the entire head; relieved after food. Vertigo, vertical headache, nausea both before and after food. Vertigo, clavus, obstinate constipation, amenorrhcea. Vertigo progressive, weakness of sight, formicatio. Vertigo, tinnitus aurium, and partial deafness. In all these combinations the collateral diseases may be cured, and yet the Vertigo remains. There are several points of interest connected with chronic stomachal vertigo which serve as a means of diagnosis from the graver forms of it. Thus it is never associated with loss of consciousness. There are intervals of hours in which the patient is perfectly free from it. It is made worse by excitement, by long fasting, and almost always the severe attacks occur when the stomach is empty. A stimulus in the form of wine or brandy relieves it, so also does food taken in small quantity. Closing the eyes to exclude objects in motion often relieves. During the attack a steady gaze on some fixed object mitigates the intensity of the sensation of giddiness. It is right to say that closing the eyes and the steady gaze are not invariably productive of relief, although subsequent treatment may prove Vertigo to have been stomachal.

In some cases the giddiness is slight, but almost constant; then it is usually associated with tinnitus aurium. More commonly it will occur several times daily, lasting from a few minutes to an hour, varying in degree, and accompanied by a singular general heaviness of the head, and a sense of heat at the vertex, which latter becomes aggravated when the Vertigo ceases. With respect to the peculiar form of vertigo, no special conclusions serving the purpose of diagnosis can be drawn. Almost always unevenness of the ground is spoken of, or an illusive opening of the ground under the feet. Objects race in the eye of the beholder, and the patient feels going round with the objects he looks at when confined to a limited space, as in a small bed-room.

There are two varieties of chronic stomachal vertigo which resist ordinary treatment. I allude to those forms complicated with, in some cases caused by, changes of tissue and alterations of the structure of the minute arteries, such as are known to occur in the persons of hard drinkers, or in those who have suffered from delirium tremens, and also in those who have suffered from latent or slight and irregular gout. It is in these cases we find the rarer forms of vertiginous perception, as, for instance, when objects in the street or in the room appear turned upside down. In such persons vertiginous perceptions and movements last for days, and are often so severe as to confine the patient to bed, incapable of the slightest movement in the upright position without assistance. Nausea and disinclination for food are the only stomachal symptoms present.
Vertigo of the Aged is often stomachal, but equally often has no reference to that organ. As years are added, arteries become atheromatous, and otherwise diseased and obstructed, the circulation in the brain becomes irregular, we may have congestion in one place and anaemia in the other—a varying condition, abundantly sufficient to explain the frequent slight attacks of Vertigo in the aged. The essential condition of the brain is always one of anaemia. (Maclagan.) It is always to be remembered that the prognosis is always more or less unfavourable when Vertigo has commenced only in old age, on account of the known pathological condition of the nerve centres.

Essential Vertigo.—Some remarks have already been made on this variety. The following case will best illustrate its characteristics:—A gentleman, aged thirty-four, of considerable energy of character and great bodily vigour, has for three years suffered from almost constant, for the last two years quite constant, Vertigo. He is in comfortable circumstances, and has been very free from the ordinary anxieties of life. He has led a temperate country life, and has never had syphilis, gout, or rheumatism. Excepting the Vertigo, he has enjoyed excellent health. He says the giddiness came on gradually, and was at first so slight that he can hardly fix the time of its first appearance. In kind it was subjective. At first, he found himself giddy on dressing in the morning; he felt as if he had taken too much wine over night, and his legs were weak, and his gait unsteady. After breakfast he was well. The attacks become more prolonged, and occurred at various periods in the day, and now he is rarely free from a sense of uncertainty rather than positive giddiness. Occasionally he becomes worse, and is obliged to sit down to prevent falling. He has no confusion or muddiness of intellect, has never lost consciousness, has no complaint of headache, dyspepsia, or disorder of any other kind. After many examinations, I have not been able to discover even functional disorder in any of the abdominal viscera. He has a soft, small, compressible pulse. The impulse of the heart is not visible; the area of dulness enlarged laterally to the right; the sounds are feeble, close to the ear, and too clearly audible to the right of the sternum. This patient has undergone a variety of medical treatment in the hands of various practitioners, including strychnine, which was pushed to the verge of producing involuntary spasms in the limbs. He has tried the hydropathic treatment, has passed a season at Vichy, but has not been able to find the slightest benefit. Very careful diet has not altered his condition, but excesses of any kind make him worse. Although there is no evidence of valvular disease, yet I cannot help connecting the feeble heart, and perhaps enlarged right ventricle, with a disordered cerebral circulation, which is itself the proximate cause of the Vertigo. I have met with two cases of this kind which were apparently hereditary. The father of one of them is now seventy-one years of age; he suffers from spasmodic asthma, and has been the victim of Vertigo for the past thirty-five years.
Vertigo from Overwork ranks next in frequency to the stomachal variety. It occurs in young persons who are underfed as well as overworked, as in some sempstresses; in the middle-aged, who to spare diet add various irregularities, as well as in the temperate and well-fed, who are constantly subject to mental anxiety and excitement. The attacks of Vertigo are of short duration, occur at intervals of some hours or days, after prolonged exertion, or poorer diet than usual; it is only a sense of the abnormal appearance of external objects at first, and occurs only on movement; it becomes more frequent, and then assumes, in addition, the character of an internal feeling of dizziness; the recumbent position always relieves, but does not even temporarily cure it. It is often complicated with stomach disorder, as anorexia, rarely nausea, with constipation, and in the female sex with menstrual irregularities. But the simple stomachic remedies do not remove, they scarcely mitigate, the Vertigo. Patients complain of a want of clearness of intellect, an incapability of sustained mental exertion, together with occipital heaviness or headache. In the worst cases, irritability of temper, restlessness, a sense of impending evil, and more rarely insomnias, are added. Sometimes the Vertigo is so easily induced by the appearance of objects in motion, that the patients are unable to go into the streets. In such cases there are functional ailments of other organs, palpitations, and lumbar pains, accompanied by the passing of phosphates in the urine. Oxaluria is not an unfrequent complication. Indeed, there is a general lowering of vitality, a universal deprivation of nutrition, and corresponding diminution of power, of which the Vertigo is only one of the exponent symptoms. This is the form of Vertigo which most often amongst business men précédes softening of the brain. Vertigo from irritation of the auditory nerve has been noticed by my late colleague, Dr. Brown-Séquard. He mentions, in his Physiology of the Nervous System, (p. 195), this result produced by injecting cold water into the ear and also by the topical application of nitrate of silver; and he suggests that such applications act in a reflex manner on the blood-vessels, producing temporary anaemia and a disordered circulation and nutrition of the brain, resulting in the production of Vertigo.

Ménière, in 1841,* established before the Academy of Medicine in Paris, that certain affections of the ear produced a series of symptoms closely resembling those attending disease of the brain, as Vertigo, dulness, uncertain walk, occasional circus movement, and even falling down, accompanied also by nausea, vomiting, and syncope. He gives also a case of a young girl who, travelling one cold night in winter during menstruation, was seized with sudden and complete deafness. Her chief symptoms were continual giddiness, and irrepressible vomiting, produced by the slightest movement. She died on the fifteenth day, yet no trace of disease was to be found in the brain, cerebellum, or spinal cord. The semicircular canals only exhibited traces of

VERTIGO.

151
disease; they were filled with reddish plastic lymph. Other cases are on record by French authors, of a similar kind, some having associated with the Vertigo, dysesthesia; that is to say, the slightest noise producing positive and even severe pain in the affected and deaf ear. It is remarkable that such cases may terminate fatally, without presenting one single symptom of feverish reaction, and without any extension of disease to the brain (Trousseau). It is well known that Vertigo in animals may be produced by puncture of the semicircular canals, as well as by wounding various parts of the base of the brain. Further information will be found in Dr. Brown-Séquard's Physiology of the Nervous System, and in the works of Schiff, Flourens, Majendie, and Claude Bernard. These are, however, matters rather of physiological than medical interest. Cases of vertiginous movements arising from disease of brain are common, such as a tendency to gyrate, to fall forwards, to one side, or backwards; but we are not able in the present state of science to draw accurate conclusions as to the seat or nature of the disease, unless it be one of a group of symptoms involving paralysis, or having other special marks of disease in a particular locality. Vertigo accompanies, to a greater or less degree, almost every organic disease of the brain, and every acute affection of this organ. Its value as a sign of disease clearly depends on its association with other symptoms; and it can only be properly appreciated in connexion with a study of those diseases of which it forms a minor part.

In a large number of hospital cases there is the association of Vertigo on movement with tinnitus aurium and partial deafness. The tinnitus and deafness appear first, and the Vertigo follows. I have never been able to trace anything like suddenness in the invasion of these symptoms; their accession is always gradual and unassociated with pain in or about the ear, or with symptoms of fever. Persons in fair average health, and without any stomach or other obvious disorder, suffer most. There seems to be some mischief of a very slow kind going on, perhaps in the semicircular canals connected with the circulation, analogous to the more acute cases recorded by Ménière. The occasional value of counter-irritation, and of iodide of potassium and of small doses of mercury, confirm this view.

TREATMENT.—Stomachal vertigo, in its acute and chronic forms, often yields to a very simple method of treatment. This consists in the exhibition of alkaline remedies and of alterative aperients continued steadily for some weeks, to be followed by bitters, and especially by the use of nux vomica or strychnia. The alkaline treatment is to be used after meals so as to neutralize any formation of acid, and to excite a freer secretion of gastric juice; the tonics to enable the stomach and bowels below to perform completely their functions. Stomachal vertigo of the severest kind yields most readily to the influence of these remedies. At the same time food is to be taken in small quantity, to be carefully masticated, at regular periods; and for drink, Vichy water mixed with a small quantity of brandy acts
most efficiently. All kinds of malt liquors are to be forbidden, whilst general hygienic measures are to be adopted. The splash bath in the morning, early retiring to rest, sleeping on a mattress in a large airy bedroom, are great adjuvants to the treatment. Freedom from the cares and anxieties of business are not less necessary. In all varieties of Vertigo it is wise to commence the treatment as if the case were stomachal, not simply because the case may turn out one of this variety, but because stomachal disorder may complicate any variety of the malady. The chronic forms of the complaint are more difficult of cure, but the same principles apply, and the treatment must be varied according to the peculiarities of the individual case, always remembering, however, that it will be wise to attack and remove the complications which are associated with it, before making a special treatment of the Vertigo. In more obstinate forms of disease connected with tissue degeneration, intertemperance, or with chronic gout, measures adapted to these several conditions will of themselves relieve the Vertigo, and prepare the way for the restoration of tone and improvement of nutrition, on which any hope of a great amelioration or cure must depend.

The Vertigo of the aged demands wine, and any plan of treatment which the case may demand must be associated with stimulants, unless (a very rare occurrence) the Vertigo be premonitory of meningitis, and is accompanied by heat of the scalp and some congestion of the conjunctiva. A most effective combination for Vertigo of the aged consists in very small doses of the bichloride of mercury, with tincture of iron and cantharides. In Vertigo from overwork, in the well-fed there are usually present restlessness, insomnia, depression of spirits, and a vague feeling of unhappiness or impending evil, for the relief of which I have found great help in bromide of ammonium, given in an effervescing form, with the addition of cascarilla. Amongst the poor, where scanty food accompanies overwork, this remedy is not of such value; we shall gain more from measures calculated directly to improve nutrition, and from slight stimulants frequently repeated. Brandy or wine, under these conditions, is a better tonic for a time than bark or quinine, which will be found most appropriate afterwards. The solutions of the hypophosphites are also especially valuable.

Essential Vertigo is most benefited by a long course of citrate of iron and strychnia, given in an effervescing form, alternating month by month with tincture of larch and small doses of digitalis. The local application of belladonna does good, although there may be neither pain nor palpitation to suggest its use. I believe it is a direct tonic to the muscular tissue of the heart, in which respect it resembles the preparations of larch, and perhaps also of digitalis. The usual conditions of rest, freedom from care and anxiety, are, of course, as essential as in the other varieties of the disease. The treatment of Vertigo arising from grave disease of brain, from softening of its structure, from aneurism, or tumour, must be involved in the treatment of these diseases.
SUN-STROKE.

By W. C. Maclean, M.D.

Definition.—A disease of the nervous system, excited by heat, sometimes following exposure to the direct rays of the sun, particularly when to heat is added the pressure of tight and unsuitable clothing and accoutrements, or both; more frequently occurring when the above conditions combine with exhaustion, induced by great fatigue in hot weather, or from the effects of high temperature, night and day, on men breathing the vitiated air of crowded barracks or ships.

The affection is generally preceded by premonitory symptoms, such as thirst, heat, and dryness of skin, vertigo, congestion of the eyes, frequent desire to micturate, followed by syncope, often instantly fatal (the cardiac variety of Morehead), or by insensibility and stertorous breathing, with or without convulsions (the cerebro-spinal variety of the same author).

In both varieties the mortality is high, and unexampled congestion of the lungs is the most common morbid appearance observed after death.

Synonyms.—Insolation; Sun-fever; Coup de Soleil; Calenture; Heat-apoplexy; Ictus solis; Erythmus tropicus.

The first is the name by which the affection is designated in the official classification of diseases in use in the British army.

History.—Sun-stroke has been known and recognised as a dangerous disease from early times. Fatal examples of it are recorded by the sacred writers, and these have been referred to by most modern authors who have written on the subject. It is worthy of note that one of the blessings promised for those who shall be partakers of the better life that is to come, is, "that the sun shall not light upon them, nor any heat,"—a promise full of meaning to the inhabitants of the "dry and thirsty land" to whom it was first made.

Men of European birth who become sojourners in Hindostan are hardly more solicitous to protect their heads from the direct rays of the sun than are the various races who are children of the soil. In China, on the other hand, the inhabitants expose their closely shaven heads to the hottest sun with apparent impunity. But when so doing...
they generally make vigorous use of their fans, as if they attached more importance to having a free current of air about their faces, than to protecting their heads from the sun's rays. Sportsmen in India constantly expose themselves in the hottest weather when in pursuit of game. Those who use reasonable precautions, who protect the head and spine by a head-dress adapted for the purpose, wear loose clothing of a suitable material, and abstain from stimulants, rarely suffer from Sun-stroke.

On the other hand, as will be shown further on, men who are made to undergo fatigue under a hot sun, dressed as British soldiers used to be in such circumstances, in tight-fitting clothes, and encumbered with heavy and badly-adjusted accoutrements, wearing a head-dress which not only gave no protection, but concentrated the sun's rays on their heads, suffered from insolation in great numbers in a most fatal form.

Sun-stroke, if we are to judge from the older medical returns of the Indian army, was not a frequent or a fatal disease. Even in the eight years ending 1853–4, as appears from Dr. Hugh Macpherson's instructive analysis of later Bengal medical returns, only thirty-eight cases are recorded. This would be very puzzling if we did not know that a great many cases, which would now be entered without hesitation under the head of insolation, were in those days "returned" under the heads of continued or remittent fevers; while those proving quickly fatal, with insensibility, convulsions, stertorous breathing, and such like symptoms, were considered to be cases of cerebral apoplexy, and registered accordingly.

For example, in the case of the two wings of H.M. 13th Regiment, referred to by Martin, which marched, after some very ill-judged exposure and drilling in the sun, from Nuddea to Berampore in the midst of the hot weather, the men suffered terribly. As the result of one march, "the day closed with a sick-list of sixty-three, and eighteen deaths," all of which appear to have been registered as cases of apoplexy. It is certain from the description left by the medical officers, that the cases would in the present day be considered to have no pathological relation to apoplexy, yet Dr. Henderson was at a loss "whether to consider them cases of remittent fever or apoplexy." (Martin.) The symptoms were clearly those of insolation. Many other examples of a like kind could be given.

The following are some of the best historical instances of insolation occurring in the field and in barracks; they have been brought forward in more or less detail by nearly all recent authors on the subject, and for the last five years I have used them in my lectures in illustration of the different forms of this affection.

In May 1834, the 68th Regiment, quartered in Fort St. George, Madras, attended the funeral of a General Officer. The regiment paraded in full dress at an early hour in the afternoon in one of the hottest months in the year, their tight-fitting coats buttoned up, their leather stocks, as stiff and unyielding as horse collars, round
their necks, heavy cross-belts so contrived as to interfere with every movement of the chest, heavy shakoes on their heads made of black felt, mounted with brass ornaments with wide flat circular tops, ingeniously contrived to concentrate the sun's rays on the crown of the head, and without protection in the way of a depending flap for the nape of the neck. So dressed, the men marched for several miles. Before the funeral parade was over the soldiers began to fall senseless—one died on the spot, two more in less than two hours. Men suffering from insolation in various degrees were brought into hospital all that night and part of next day. The cases that did not prove fatal, although their real nature was correctly understood by Dr. Russell, acting-surgeon of the regiment, were all registered as cases either of continued or ephemeral fever. The symptoms in the fatal cases were thirst, excessive heat of skin, extreme prostration, immediately followed by gasping respiration, coma, stertor, lividity of the face, and death. After death no morbid appearance was found in the brain, but in the lungs of all there was extreme congestion. There lingers a tradition of this parade in Madras to this day.

The 63d Regiment suffered in the same way, at the same place, and under circumstances precisely alike. (Martin: Influence of Tropical Climates.)

Of the next example the writer of this article was an eye-witness. The 98th Regiment joined the expeditionary force under Lord Gough in China in 1842. The regiment came from England in the Belleisle, an old 74-gun ship, and suffered from over-crowding. On the 21st of July the 98th took part in the attack on Chin-Kiang-Foo, the final military operation of the war. The men were dressed precisely as already described in the case of the 68th Regiment. In this condition they had to take possession of a steep hill exposed to the fierce rays of the sun shining out of an unclouded sky. A great many men were struck down by the heat, about fifteen died on the spot, falling on their faces, as Dr. Parkes, on the authority of another eye-witness, has correctly described (Practical Hygiene); they gave a few convulsive gasps, and died before anything could be done for their relief.

The best history of an outbreak of insolation with which the writer is acquainted is that given by Dr. Barclay, of the 43d Light Infantry, and published in the second number of the Madras Quarterly Journal of Medical Science. The 43d Regiment performed one of the most extraordinary marches on record, having marched from Bangalore, in the Deccan, to Calpee, in Central India, a distance by the route taken considerably exceeding eleven hundred miles. The exigencies of the public service at that time (1857–58, memorable as the years of the mutiny in Bengal) were such, that this march, with the exception of a few brief halts at stations by the way, was made continuously, and a great portion of it was accomplished during the hottest season of the year. The men were exposed to a very high temperature by night as well as by day.

Dr. Barclay, while in a valley at the foot of the Bisranguunge Ghât,
observed the thermometer at 118° Fahr. in the largest tents during the day, 127° in the smallest, and on one occasion he observed it at 105° at midnight. This prolonged exertion and continuous exposure to excessive heat by night as well as by day, exceeded the limits of human endurance. When they reached Nagode, "the indications of exhaustion in the altered looks of the men, their loss of flesh, and their evidently failing strength, were so obvious that they forced themselves on the observation of every one." But further on, on the march from Humeerpore to Calpee, Dr. Barclay records, "There was scarcely a man in the regiment whose strength was not reduced to a level with that of a child."

It is remarkable that no case of insolation occurred until the 28th of April, i.e., until the 43d had marched 969 miles—until, in fact, the signs of exhaustion, first noted by Dr. Barclay, were apparent. From that date they increased in frequency. When at the foot of the pass, named above, cases "were brought to the hospital tents at every hour of the day and night, and although a large proportion of them recovered, two officers and eleven men were buried under one tree in the neighbourhood of the camp." (Dr. Barclay on the Natural History of Insolation).

But, as has been said, insolation occurs in barracks as well as in the field. The two best and most carefully observed examples of this form of the affection are those recorded by Dr. Butler, of the 3d Light Cavalry, at Meean Meer, and by Mr. Longmore, then surgeon of the 19th Regiment, stationed at Barrackpore, in Lower Bengal, and both published in the Indian Annals of Medicine.

Dr. Butler records that his men had not been overworked or fatigued, but at a time when the heat was excessive (102° in the shade), they were overcrowded. "Assuredly," says Dr. Butler, "those barracks most crowded, least ventilated, and worst provided with punkahs and other appliances to moderate excessive heat, furnished the greatest number of fatal cases."

Mr. Longmore's evidence on the same point is most important. Out of sixteen cases thirteen occurred in barracks or in hospital, and Mr. Longmore notes that one-third of his cases, and nearly half the deaths, "occurred in one company of the regiment quartered in the barrack which was manifestly the worst conditioned as to ventilation, and, indeed, in every sanitary requirement."

Mr. Longmore remarked also that "the patients seized in hospital were lying in two wards on the leeward side, and from circumstances of situation the warmest and most confined."

Insolation has frequently been observed on board ship, but almost always under conditions similar to those in barracks; that is, where overcrowding and impure air are added to the influence of excessive heat. Insolation is not uncommon on board the mail steamers in the Red Sea in the hot months of August and September; it has been observed that most of the cases occurred while the sufferers were in the horizontal position in their ill-ventilated cabins.
M. Bassier, Surgeon in the French navy, reports (Dissertation sur la Calenture) that in the month of August 1823, the man-of-war brig Le Lynx, cruising off Cadiz, had eighteen cases of insolation, out of a crew of seventy-eight men. The heat was excessive ("33 à 35 degrès cent.") and much aggravated by calms. In this case the ship was overcrowded: "le bâtiment, très petit, offrait peu d'espace pour le coucher de l'équipage."

M. Boudin (Statistiques Médicales) quotes from the same author the case of the French man-of-war Duguesne. This ship, while at Rio Janeiro, had a hundred cases of insolation, out of a crew of six hundred men. Most of the men were attacked, not when exposed to the direct heat of the sun, but at night when in the recumbent position—that is, when breathing not only a hot and suffocating, but also an impure air.

Etiology.—I have already remarked, that men will bear a high temperature in the open air with comparative impunity, provided (a) it is not too long continued, (b) that the dress be reasonably adapted to the temperature, (c) that the free movement of the chest be not interfered with. As already remarked, British sportsmen in India often pursue their exciting amusement in the hottest weather; but as they are careful to dress suitably, they seldom suffer from insolation.

It will be remarked, that in all the examples of insolation in the direct rays of the sun given above, the sufferers were all soldiers dressed and accoutred precisely as men ought not to be in the circumstances in which they were placed. Dress and accoutrements, then, are powerful aids to high temperature.

The case of the 43rd Light Infantry, as related by Dr. Barclay, and above referred to, brings out another predisposing cause, which appears to exercise a powerful influence, viz. exhaustion, the result of prolonged exertion.

This appears to act in various ways. First, there is a great waste of tissue, for a time,—that is, so long as the functions of the skin and the bowels continue in tolerable activity, the blood is maintained in a state probably not far from its normal condition. But as the exertion continues under a temperature seldom falling below 90° or 92° Fahr., and often reaching, as we have seen, 100°, 107°, and sometimes 117°, in a well-made tent, the function of the skin ceases, and the result of this must be not only the loss of the cooling effect of evaporation, but also blood impurity. Again, all observers note that under such circumstances, obstinate constipation of the bowels is a constant condition, still further promoting this impure condition of the blood. But not only may we reasonably suppose that the blood must be in an abnormal condition from the above causes; it is very imperfectly replenished by healthy, well-digested food. "The appetite," says Dr. Barclay, "gradually failed, and a feeling of nausea was generally complained of, the sight of food often exciting loathing."
In other instances there was nearly complete anorexia. It may be supposed that the activity of the kidneys may, to some extent, compensate for the lost function of the skin and the impaired eliminating action of other organs. But not to dilate on the fact that frequent micturation, although a common, is by no means an invariable symptom in the premonitory stage of insolation, is it not possible that the inability to retain urine in the bladder is quite as much due to its quality as its quantity? "I cannot hold my water," was the almost invariable complaint of Dr. Barclay's men; and Mr. Longmore carefully noted the same thing in his cases.

Careful observations are wanted to determine whether this dribbling of urine is not more due to its stimulating quality than to any excess in quantity. If we look again to the cases quoted as occurring in barracks and ships, it will be seen that another cause besides heat was in operation. In all the examples given of insolation in barracks, the observers have noted the ill-ventilated, overcrowded condition of the places where the majority of the cases occurred. Many of the small bungalows occupied by officers in military stations in India, are quite as hot as any barrack-room, yet nothing is more rare than to see officers affected with this form of insolation. In the French ships, overcrowding and imperfect ventilation, with their necessary consequence, impure air, were noted by the surgeon who reported the cases.

It is then evident, from the above facts, and from many more of the same kind that might be adduced, that the pressure of tight and unsuitable clothes and accompaniments, excessive fatigue, with all its consequences, and the impure air of ill-ventilated barracks and ships, are powerful predisposing causes of insolation.

But it cannot be doubted that heat, and, speaking generally, heat long continued, is the true exciting cause of this formidable affection. It is difficult to say with any exactness, what is the point in the scale at which danger begins, but it is evident that the effects of heat are modified by the circumstances in which men exposed to it are placed.

There is no agreement among observers as to the effects of extreme dryness or moisture in increasing or diminishing the effects of heat. Insolation has been observed in both conditions. In the case of the 43d Regiment, the hot, dry land winds were blowing. Mr. Longmore also notes the extreme dryness of the air at Barrackpore during the outbreak there; and in all the examples given, the disease disappeared with the first heavy fall of rain, attended with a rapid fall in temperature. On the other hand, Dr. Baxter, of the 93d Highlanders, who gives four cases of Sun-stroke observed at Sealkote, considers that Sun-stroke is much more likely to occur when the atmosphere "is largely impregnated with watery vapour." (Dublin Quart. Journal of Med. Science, No. 81, Feb. 1866.)

Mr. Naylor also is of opinion that cloudy days, with "a moist condition of the atmosphere," favour the occurrence of insolation.
SUN-STROKE.

(Morehead’s Clinical Researches). Exact observations on this point, with the wet and dry bulb, are much required.

It would appear that a hot and moist condition of the air is most favourable to the production of insolation in barracks, because not only does such a condition diminish the cooling effect of evaporation from the skin, but interferes with the artificial means used to reduce the temperature of the overheated rooms.

Duration.—The disease may prove fatal, as we have seen, in a few minutes, or the symptoms may last from one to forty-six or forty-eight hours.

Termination.—The disease terminates either in death or recovery, which may be complete or partial, certain sequels in a considerable number of cases appearing. These are persisting headache, the pain being either fixed or shifting; a chorea-like affection of the muscles, generally those of the forearm and hands; epilepsy, particularly in those who have suffered from this disease in youth, or who have a hereditary tendency to it. In some cases mental weakness, which may prove permanent, follows Sun-stroke. In one example, that of an officer of distinction, who lost his hunting cap while pursuing a wild hog at speed, and in the eagerness of the chase rode for miles bare-headed, Sun-stroke was the result; from that hour his mind was affected, and complete recovery never took place.

Symptoms.—Dr. Morehead has divided Insolation into three varieties,—the Cardiac, the Cerebro-spinal, and the Mixed. In the present state of knowledge this classification is useful, and it certainly appears to be founded on correct pathology.

In the Cardiac variety, although it is probable that the sufferer is himself conscious of some premonitory symptoms, there is seldom time for their full development so as to attract the attention of bystanders before the patient falls, gasps, and in some severe cases expires before there is time to do much, or anything, for his recovery, death taking place by syncope. This is the form most frequently seen in men exerting themselves in the heat of the sun when dressed and accoutred, as were the soldiers of the 98th Regiment at Chin-Kiang-Foo, or at the funeral parades at Madras above described.

In the so-called Cerebro-spinal cases, premonitory symptoms generally give notice of the coming danger. These are heat of skin—this is never absent; the heat is attended with extreme dryness, and is remarkably ardent and stinging, exceeding that of the worst form of remittent fever, which is sometimes as high as 107° Fahr.—giddiness, congestion of the eyes, extreme debility, nausea, and frequent desire to micturate. This last symptom is much insisted on by Longmore, and Dr. Barclay says that “I cannot hold my water” was often the first complaint made by many of his patients. It is a notable thing that headache is by no means a common symptom; it does not appear to have been complained of in a single instance in Dr. Barclay’s cases.
Again, a wild shout of laughter, or an attempt to escape in terror from some imaginary enemy, sometimes precedes the more serious symptoms, to be presently described.

M. Bassier, in the case already referred to of the French man-of-war at Rio Janeiro, mentions that the utmost difficulty was experienced in preventing the men from throwing themselves into the sea:—"Ils devenaient incohérents dans leur discours, poussaient des cris, menaçaient de geste et de regard, entraient en fureur, et semblaient mettre tous leurs soins à découvrir une issue qui leur permett de s'élancer à la mer." * On one occasion I saw a man in this condition suddenly possess himself of the arms of a sentry to defend himself from an imaginary enemy.

It is not by any means always that we have an opportunity of seeing the above premonitory symptoms. Where men in barracks are sensible of the approach of any of them, they generally assume the recumbent position, and in that state pass into the stage of coma, the attention of their comrades being first called to their condition by their stertorous breathing.

After a longer or shorter continuance of the above symptoms, the patient becomes insensible; the heat and dryness of the skin augment; the respiration becomes hurried, noisy, laboured; the pupils contract, and are quite insensible to light; the conjunctiva become more congested, "pinky" (Barclay); the heart acts tumultuously; the pulse in men in a sthenic condition being at first rapid, but distinct, but as the case progresses unfavourably, becoming compressible, feeble, and irregular; convulsions are frequent, but not invariable; sometimes they appear early, in other cases they immediately precede death.

Dr. Barclay expressly says, that "In a large proportion of cases, from the commencement of the attack to its termination in death, the patient never moved a limb or even an eyelid."

In the Mixed form of Morehead, the symptoms partake of both varieties, and the fatal event is brought about partly by coma, partly by syncope.

* Frenchmen under the influence of insolation seem strongly compelled to self-destruction.

Boudin relates that in 1836, "pendant une expédition du Général Bugeaud dans la province d'Oran, on a pu compter, en quelques heures, 11 suicidés et 200 hommes atteints de congestion cérébrale, sur un colonne de quelques milliers d'hommes." The same author gives a striking example of the terrible effects of heat on a body of Belgian soldiers on the line of march, which may be fairly taken as another instance of the evil effects of tight clothing and accoutrements:—

On the 8th July, 1853, a body of men, 1,200 strong, marched from Bevarloo to Hasselt. They started at eight o'clock in the morning. Only 500 reached Hasselt in the evening, nineteen perished en route, and a great number in a state of furious delirium were taken to hospital. I do not think that anything so disastrous as this occurred under an Indian sun during the years of the mutiny in Bengal and Central India. It is a remarkable thing that on this occasion the temperature did not exceed 38° or 35° centigrade. In connexion with this M. Boudin observes that two well-known Egyptian astronomers, MM. Mahmoud and Ismael, who were in Brussels on that day, assured M. Quetelet, that they suffered as much from a temperature of 30°-7 centigrade in that city as in Cairo under a temperature of nearly 50°: "nouvelle preuve de la nécessité de tenir compte de la qualité de la température."
**SUN-STROKE.**

**Diagnosis.**—The diseases with which this affection appears to have been confounded, are cerebral apoplexy, and various forms of fever, such as ardent continued fever, and even some of the graver forms of remittent. With the first named it has no pathological relations at all, and it is to be regretted that the term “apoplexy” continues to be appended to any of the names in use to distinguish this disease. In both apoplexy and the cerebro-spinal variety of Sun-stroke, there is coma; but the pulse in apoplexy is slow, generally full, sometimes intermitting. In Sun-stroke, it is quick and sharp. In apoplexy the breathing is slow, irregular, and explosive in expiration; in Sun-stroke, it is rapid, noisy, but not explosive. In apoplexy the pupils are usually dilated, or one is more so than the other; in Sun-stroke both are contracted, and the conjunctivae are deeply congested. The skin in apoplexy is not hot, and is often cold and moist; in Sun-stroke, it is always, except in some rare examples of the cardiac variety, very hot and excessively dry.

Paralysis (hemiplegia) is the almost invariable result of cerebral haemorrhage; it never follows Sun-stroke.

From ardent continued fever, the premonitory symptoms already enumerated, more particularly the frequent micturation, and the early supervention of insensibility, will distinguish it. The above, with the history of the case, ought to suffice to distinguish it from the hot stage of remittent fever.

**Pathology.**—On one point, at least, all modern pathologists are agreed, viz. that the superheating of the blood which precedes and accompanies Sun-stroke, has a depressing and not a stimulating effect on the nervous centres; and as the general recognition of this has had a powerful effect in leading to a more rational form of treatment, it is a decided step in advance.

The opinion given by Dr. Morehead, that the sthenic constitution of the newly-arrived European predisposes to the cerebro-spinal variety of insolation, must, I venture to think, be taken with some qualification. Without doubt it was this variety that prevailed most in the 43d Light Infantry; yet, from Dr. Barclay’s description of the miserable condition to which his men were reduced before the disease appeared among them, they were in anything but a sthenic condition. On the other hand, the men of the 63d Regiment at Madras, and the 98th at Chin-Kiang-Foo, fresh from Europe, were in the very opposite condition; yet it is clear, from the description given of the symptoms, that they suffered from the cardiac variety. It appears to me that the constriction of the men’s chests by tight coats, the pressure of their unyielding stocks and accoutrements, had much to do in determining the particular symptoms—an opinion, strengthened by all that I have learned from a careful study of the effects of dress and accoutrements on the organs of circulation and respiration, and by the revelations of the committee appointed to investigate this subject. At Chin-Kiang-Foo, the soldiers of the 18th Royal Irish, the 49th, and...
55th Regiments, were quite as much exposed to the sun as the 98th; they did not suffer from insolation, but they marched and fought without stocks, and with their jackets open.

I am also strongly impressed with the opinion that blood impurity, induced by the vitiated air of overcrowded barracks, tents, and ships, powerfully aids heat in bringing about that condition of the nervous centres which leads to the development of the terrible symptoms of insolation. Were it not so, the high temperature so often observed in the small houses and tents, particularly of many junior officers, would make this disease more common than it is among them.

**MORBID ANATOMY.**—The blood is invariably found in the same condition as after death from lightning, or blows on the epigastrium,—that is, fluid.

When death occurs so quickly as it generally does in this affection, there is really no time for much organic lesion; some congestion of cerebral vessels is a common, but by no means an invariable, appearance.

The most common condition in all varieties, but more particularly in the cardiac, is congestion of the lungs, with distension of the right heart. This congestion is more complete in this than in any other disease.

**MORTALITY.**—If Sir Charles Napier is correct in the statement he makes in a letter published in his Life, that out of forty-four cases of Sun-stroke which occurred at Nussurpoor on the 15th of June, 1843, forty-three proved fatal, this is the highest mortality on record.

Dr. Barclay only included severe and well-marked cases in his table, and his death-rate was 42.734 per cent.

Dr. Butler's at Meean Meer was 43.3 per cent.

Dr. Morehead gives the following table:

<table>
<thead>
<tr>
<th></th>
<th>Treated</th>
<th>Deaths</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mr. Hill's collected cases</td>

**PROGNOSIS.**—The most unfavourable signs are prolonged and complete insensibility, without movement; (this is a much more unfavourable symptom than occasional convulsions;) intense heat of skin, persisting notwithstanding the free use of the douche; increasing congestion of the eyes; tumultuous action of the heart; failing pulse; lividity of hands and feet.

If convulsions appear after such symptoms have been present for some time, they indicate the near approach of death.
PROPHYLAXIS.—1st, In barracks. The measure now about to be
carried out in the construction of barracks in India, viz. having dor-
mitories in which not more than from ten to fifteen men can be
accommodated, will do more to diminish the frequency of barrack
Insolation than any single remedy with which I am acquainted.

Meanwhile, I cannot too strongly insist on the propriety of at once
pitching a sufficient number of tents for dormitories, whenever the
night temperature rises to 90°, so as to diminish, by at least one-
half, the number of men in barracks during the night. The manner
of cooling both tents and barracks is so well understood in India, that
it is useless to insist upon it here.

In future, troops in India are never likely to be drilled in a hot sun,
or paraded to attend military funerals in heavy marching order at
3 P.M. Even in that “military hot-house” Madras, where such customs
“lingered long and latest died,” it is to be hoped they will never more
be heard of.

As a rule, save under the pressure of real military necessity,
European troops are not likely to be moved during the hot weather;
and where such a cruel necessity exists, the terrible lessons taught
during the Mutiny are not likely to be forgotten.

The necessity for light clothing, suitable protection for the head,
neck, and spine, are now well understood and provided for by existing
regulations.

At such times it will be good economy to engage an extra number
of water-carriers, so that a never-failing supply shall be at hand, not
only for drinking, but for douching purposes. I cordially assent to the
practical suggestion urged by Dr. Barclay, that the hospital tents used
on such occasions should be the best that can be made, and should be
furnished with the best appliances, to maintain as low a temperature as
possible. If patients suffering from Insolation can quickly be brought
into an hospital tent 15 or 20 degrees cooler than the one from
whence he has been taken, his chances of life will be immeasurably
increased. Nor is it necessary to say much on the good effects of
temperance.

It is to be hoped that the day is not distant when the spirit ration
will be a thing of the past.

TREATMENT.—In the days when Insolation was commonly mis-
taken for cerebral apoplexy, the lancet was usually the first resource.
The mortality even now, under a mode of treatment more in accordance
with sound pathology, is often exceedingly high; but when blood-
letting was the rule, recovery was the rare exception.

A few years ago, in an outburst of Insolation on board one of the
mail steamers in the Red Sea, this was the mode of treatment pursued.
A fatal issue resulted in every case.

During active service in the presence of the enemy, an officer of
rank had Sun-stroke.

The assistant-surgeon in medical charge of the battery where this
A SYSTEM OF MEDICINE.

happened had the sufferer instantly removed to the nearest shade, stripped him, used the douche freely, and had the satisfaction to see his patient revive and consciousness return. An official superior, "an older, not a better" physician, unhappily coming up at this critical moment, insisted on opening a vein: a few ounces of blood trickled away, and so did the life of the officer. Mortal syncope immediately followed the operation.

It is needless to insist on this point, for, as Dr. Morehead has observed, "there is now great unanimity of opinion" on the treatment of Sun-stroke, and by universal consent the lancet has no place in it.

At the earliest possible moment let the sufferer be carried to the nearest shade, stripped, and assiduously doused with cold water over head, neck, and chest. If this be effectually and quickly done, the powerful impression on the cutaneous nerves will soon re-establish respiration, at first by gasps and catches, soon in a more regular and tranquil manner. It will also reduce the heat of skin. It may require to be done again and again; in hospital it may be necessary to envelope the patient in a wet sheet, and to ply the fan or punkah over him vigorously until the skin is reduced to a more natural temperature.

The patient should be encouraged to drink freely, and if vomiting follows, this will often aid in relieving the congestion of the lungs. The douche used as above described is a powerful remedy, and, as Dr. Abercrombie long since pointed out, it may be abused, particularly if it is applied too long to the shaven head. Morehead has also well cautioned us against its prolonged use in a routine way, when the skin is cold and clammy, and the respiration sighing—under such circumstances we must restrict ourselves to dashing water over the face and chest. When the heat of the skin is excessive we may avail ourselves, if ice is at hand, of Dr. Parkes' suggestion, and give an enema of ice-cold water. We should also apply ammonia, with the usual caution, now and then to the nostrils. The bowels being always constipated, the sooner they are relieved the better, by the use of purgatives and enemata. If the skin refuse to act, even after the free use of the douche, and maintains its high temperature, a trial may be given of Warburg's Tincture, the most powerful sudorific with which I am acquainted.* The occurrence of moderate diarrhoea seems to favour recovery. Support and a judicious use of stimulants must not be neglected.

If sensibility be not restored and maintained by the douche, a blister should be applied at once to the nape, and, if need be, to the shaven head. There is much unanimity as to the good effects of this measure.

Professor Sir James Simpson, of Edinburgh, long ago taught us how invaluable the inhalation of chloroform is in the convulsions of children depending on cerebral irritation. In India I have saved the lives of many by acting on this advice. Dr. Barclay in like manner found chloroform inhalation useful "in the convulsive form of the disease,

* Vide article Remittent Fever, vol. i. p. 80.
attended with extreme nervous irritability,"—a class of cases in which, he adds, "the douche is inadmissible from the agony it occasions." In some instances life was saved by this remedy; in all it was prolonged.

TREATMENT OF THE SEQUELæ OF SUN-STROKE.—Although by careful and judicious treatment many recover from the immediate effects of Sun-stroke, not inconsiderable numbers are incapacitated by it for service in India, or in any hot climate, without at least a more or less prolonged stay in a cold climate. This is precisely what we see after concussion. Out of the large number of cases of concussion I have seen in India from falls from horseback, I have hardly seen one make a complete recovery without a visit to Europe.

Persisting headache is one of the most common sequels of Sun-stroke.

At Netley during the invaliding season we are never without such cases, and very obstinate and intractable some of them are. When the pain is fixed and severe, long-continued counter-irritation to the nape, and a course of iodide of potassium, sometimes permanently relieve. But I have seen some men discharged quite unrelieved by treatment.

Great attention to the function of the skin forms an essential part of the treatment in all the varieties of the sequelæ of Sun-stroke, for it is impaired in all. Frictions, bathing, exercise in the open air, are essential. When the headache is not fixed, but shifting, it will often be found to depend on a weak condition of the digestive organs, and careful treatment suited to the peculiar features of each individual case is required.

In epilepsy following Sun-stroke the prognosis is generally favourable. The fits usually subside on the patient being removed to a temperate climate.
WASTING PALSY.

By William Roberts, M.D. F.R.C.P.

Definition.—A chronic disease, consisting in a progressive atrophy of the voluntary muscles, independent of any antecedent motor or sensory paralysis. The disease attacks the muscles in groups: in some cases it is partial, and limited to the extremities; in other cases it is general, and implicates the muscles of the head, neck, and trunk.

Synonyms.—Paralysis Atrophica; Progressive Muscular Atrophy; Cruveilhier's Atrophy; Atrophie Musculaire Progressive (Fr.); Progressive Muskelatrophie, Progressive Muskel-lähmung (Gér.).

History.—Cases of extreme wasting of the muscles of the upper and lower limbs, without loss of voluntary power, were published in this country, in the earlier decades of the present century, by Cooke, Bell, and Darwall; but the establishment of the affection as a distinct type of disease is due to the labours of Cruveilhier, Aran, and Duchenne, in France, in the years 1851-53. The present writer collected all the information existing on the subject up to 1858, in an Essay published in that year.* To this Essay the reader is referred for the earlier notices of the disease. Since 1858 the pathology of Wasting Palsy has been elucidated by the investigations of Gull, Lockhart Clarke, Luys, and others.

Etiology.—The subjects of Wasting Palsy are mostly found among young adults and middle-aged individuals; but children are not unfrequently attacked. The mean age of eighty-eight cases collected by me was thirty years—the youngest was only two years of age, and the oldest sixty-nine. The male sex is considerably more liable to the disease than the female (about six males to every one female). This disproportion probably depends, mainly, on the greater and more sustained muscular exertion which men's occupations demand; also on the greater exposure to cold and external violence of individuals of the male sex. Women of the working-class—washervomen, domestic servants, sempstresses, &c. are seemingly not much less liable to Wasting Palsy than men employed in kindred occupations; but

females belonging to the easy classes enjoy a remarkable immunity from this disease. It is, however, somewhat difficult to explain why cases arising from hereditary influence should occur more frequently among males than females.

Partial or local muscular atrophy prevails mostly among handycraftsmen—mechanics, masons, smiths, miners, needlewomen, scriveners, labourers, and domestic servants. The subjects of general Wasting Palsy are found equally in every grade of life.

The influence of consanguinity in the production of this disease has been remarked in a number of instances. The present writer collected the history of ten families in which a tendency to Wasting Palsy prevailed. In four of these families the disease was confined to two brothers in each. Dr. Meryon's first described cases were four boys who had six healthy sisters. In another family mentioned by him all the boys—namely, two—were affected, while the two sisters were healthy. A sea-captain, whose history is related by Aran, had lost two maternal uncles and a sister by the same disease. In another instance, recorded by the same observer, the patient's two aunts had died from general muscular atrophy; and, in a family known to Oppenheimer, two uncles and a cousin were already deceased, while another cousin and two brothers still suffered from the same disease. Altogether these ten families included twenty-nine individuals affected with Wasting Palsy, and of these only four were females. Cases arising from hereditary influence present another well-marked feature—in nearly all of them the disease became generalized, and consequently tended to a fatal termination.

As a rule, the subjects of Wasting Palsy have been persons of good physical development: in several cases the patients are reported to have been men of remarkable muscular power and activity; in a few instances—nearly all of which were associated with a hereditary proclivity to the disease—a certain weakness existed from early youth.

The exciting causes of Wasting Palsy (excluding hereditary predisposition) may be ranged under three heads: namely, excessive muscular action, cold, and disease or violence affecting the spine. In a considerable number of cases, however (36 per cent.), no reasonable cause could be assigned for the breaking out of the disease.

Aran directs attention to the fact that the particular muscles which are necessarily in long-continued contraction in persons following certain mechanical trades (masons, milliners, shoemakers, smiths, &c.), are those which are first invaded and most deeply involved. In persons of this class the muscles of the shoulders, arms, and hands are first affected, and very frequently the atrophy is permanently limited to these parts. There are numerous exceptions, however, to this rule.

Cases arising from cold (wearing of damp apparel, immersion of the limbs in cold water, rapid cooling of the perspiring surface, exposure to inclement weather) are marked by a train of neuralgic or so-called
rheumatic pains in the affected parts, either at the onset of the atrophy, and ceasing when this has fairly set in, or continuing throughout its progress, and imparting a special character to the symptoms. The invasion of the disease in this class of cases is often somewhat sudden, and accompanied by cramps and twitching of the muscles.

In cases traceable to cold, the wasting is more apt to extend to the muscles of the trunk than in cases due to overwork. Of twenty-five cases attributed to overwork, eighteen were partial and only seven general; whereas, of the sixteen cases charged to the agency of cold, six were local and ten general. These two causes are often in operation together: the miners in my neighbourhood, who work in damp or wet excavations, are frequent victims of Wasting Palsy.

The connexion of Wasting Palsy with injury or disease directly or indirectly implicating the spinal cord, has of late years attracted increasing attention; and the interpretation of these cases has an important bearing on the pathology of the disease, as will be more particularly noticed hereafter. The history of some antecedent violence occurs too frequently in the reports of cases of Wasting Palsy to allow of its being set aside as a merely fortuitous circumstance, though the precise connexion between the injury and the subsequent atrophy is often obscure. In a youth under my care at the Manchester Infirmary, who ultimately died from implication of the respiratory muscles, the first symptoms of atrophy in the ball of the right thumb occurred six months after the fall of a bale of cotton-cloth on the nape of the neck. The immediate effects of the injury were confined to slight stiffness of the neck, and occasional pains extending down the arms. Valentiner records a case in which the first failure of health followed a fall on the back from a height of eight or ten feet: yet the atrophy did not appear until six years after. Bergmann’s patient* fell on his back from a horse, and lay for a while unconscious. From this time he suffered pain and stiffness in moving the head; afterwards, and very slowly, a weakness in the shoulders came on, which ended in complete atrophy of the muscles around the shoulder joints. In a remarkable case recently reported by Dr. Thudichum and Mr. Lockhart Clarke, a gentleman, aged 54, suffered what he considered a slight injury. In jumping across a flower-bed for a wager, he came down heavily on his heels, and then fell backwards upon his head. He was stunned for a time, but gradually recovered, and, after some days’ confinement to his bed, appeared to be quite well again. It was, however, soon perceived that a great change took place in his habits. Having been extremely fond of manly sports and exercises—rowing, cricketing, riding on horseback, dancing, and the like—he discontinued to take part in any of these, although he continued to go every autumn to the Scotch moors for the purpose of shooting grouse. Five years after the above-mentioned accident, while engaged in this last-named sport, he perceived that his right leg had lost a part of its usual strength. From this time gradual atrophy and loss of power in the

muscles crept over the patient, until at length death took place from failure of the respiratory muscles. Wide-spread degeneration of the spinal cord was found after death. (Beale's Archives of Medicine, 1863.)

In other cases, disease, manifestly primary, of the spinal cord is followed by complete atrophy of certain groups of muscles. In a case, published a few years ago in the London Medical Review by the present writer, a young man suffered from acute general paralysis of all the muscles of the extremities, and of most of those of the trunk. The intellect was not affected. Gradually, in the course of months, the patient recovered the power of the muscles, but after complete restoration of the remainder of the body, the intrinsic muscles of both the hands and feet passed into a state of total atrophy, and still continued in the same condition. In the so-called essential paralysis of infancy and childhood—which is evidently of spinal origin—certain limited groups of muscles not unfrequently pass into a state of permanent atrophy, while the remaining portions of the paralysed members recover their mobility.

Certain other exciting causes of Wasting Palsy are sometimes doubtfully mentioned—namely, constitutional syphilis, venereal excesses, onanism, and antecedent zymotic fevers.

**Symptoms.**—The invasion of Wasting Palsy is always gradual, and the disease has usually been in progress some weeks or months before the patient discovers its existence. The first symptom perceived is a certain weakness in the affected member: the tailor finds he cannot hold his needle; the shoemaker cannot thrust his awl; the mason fails to wield his hammer; the gentleman experiences an awkwardness in handling his pen, in pulling out his pocket handkerchief, or in putting on his hat. Some such incident calls attention to the affected limb, which is then usually discovered to be more or less wasted and shrunk.

The disease begins, in the great majority of cases, in the upper extremities, either in the ball of the thumb and hand, or in the shoulder—much more commonly in the former than in the latter. Sometimes, however, it begins in the muscles of the neck, of the face, the tongue, in the thigh, the leg, or the foot. The extension or spread of the disease follows an erratic course. In the immense majority of cases the disease is permanently limited to one or a few groups of muscles in the upper or lower extremities; in other cases, and these are by far more formidable, the atrophy invades successively the voluntary muscles of the entire body, trunk and extremities. The only muscles which, as yet, have not been known to be attacked, are those of mastication, and those which move the eyeball. When the atrophy is confined to certain regions of the extremities, the life of the sufferer is not imperilled; but when the trunk is invaded, and the muscles of respiration participate in the disease, death by suffocation is the ultimate result.
The wasting and disappearance of the muscles produce notable changes in the configuration of the body. The natural rounded contour of the limbs is replaced by an unsightly flattening; the bones stand out in unaccustomed distinctness, giving to the member the appearance of a skeleton clothed in skin; but the skin itself, and the subcutaneous cellular tissue, undergo no change, and cannot be distinguished from the integuments of healthy parts. Certain distortions of the head, trunk, and extremities are also occasioned by the unequal wasting of opposed groups of muscles—those less atrophied overcoming the resistance of those more diseased. These changes of configuration are a marked feature of wasting palsy. The hand is frequently the seat of a very singular deformity—namely, the "claw-shaped" hand, or "main en griffe" of French writers. The palm is robbed of its muscular cushions; flat planes or hollows occupy the sites of the thenar and hypothenar eminences; the hollow of the hand is traversed by the visibly prominent diverging flexor tendons, which are stretched between the wrist and the bulging bases of the fingers; the proximal phalanges are bent backwards, away from the hollow of the hand, while the middle and distal ones, inclined in an opposite direction, are in a state of continual semi-flexion. The back of the hand is hollowed out in long furrows, corresponding to the interosseous spaces, and the first joints of the fingers are pulled backwards, giving the hand a broken-backed appearance.

Passing up the limb, the forearm is found flattened, or even hollowed, on its anterior and posterior aspects. When the shoulders are affected, the whole arm dangles powerless at the side; the roundness of the shoulder has given place to a flattening, and the head of the humerus, the acromion, and the coracoid processes are plainly designed through the thin covering of skin. If the serratus magnus be destroyed, the angle of the scapula is tilted upwards and inwards, and stands prominently out from the trunk. Corresponding deformities are witnessed when the lower limbs are invaded: the foot is distorted by the unequal involvement of its extrinsic and intrinsic muscles, and contractions of the toes on the sole, deflections of the foot inwards, or of the heel upwards, are produced—interfering very seriously with the steadiness of progression.

But perhaps the most remarkable of all the anatomical changes are seen in the face, when the muscles of expression are destroyed. The face is veiled, as it were, by an impenetrable mask; no emotion changes its unvarying aspect—the expression is always solemn, stolid, and unmoved. The muscles of the eyeballs are, however, spared, and by their movements alone, in the later periods, the mind holds an imperfect communion with the external world. The oral and buccal muscles are usually invaded early, and the saliva dribbles over the lips. When the muscles of the neck are involved, the head falls forward—the chin resting on the sternum—or, laterally, the head falling over on the shoulder.

When the abdominal muscles are implicated, the lumbar curve is
enormously exaggerated by the unopposed action of the erector spinae, and the belly projects in front, while the chest is thrown back as a counterpoise. The invasion of the lingual muscles leads to a falter in the speech, and to imperfect comminution of food in the mouth. The involvement of the laryngeal muscles produces a change in the voice, which loses its register, and is finally reduced to a monotone. When the diaphragm and intercostals are reached, violent suffocative fits of coughing are occasioned; the play of the chest is at length so reduced that a slight additional difficulty to respiration proves fatal. Dissolution is usually brought about by a bronchitic seizure; the air-tubes are speedily clogged with mucus, which no efforts of the patient can dislodge, and rapid asphyxia closes the scene.

When the disease is partial in its extension, it is observed that certain parts of the body, and certain groups of muscles, are much more obnoxious to its inroads than others. The muscles of the trunk are less liable than those of the extremities, and those of the lower extremities are far less frequently affected than those of the upper. Of sixty-two cases of partial Wasting Palsy collected by me, the upper extremities were alone affected fifty-one times, the lower extremities alone five times, and the upper and lower together seven times. The right arm was much more frequently attacked than the left, and the hands oftener than the shoulders. As a general rule, it was found that when one limb was attacked, its fellow of the opposite side shared its fate; that when the disease was unilateral, the right side was more likely to be its seat than the left.

One of the most striking characteristics of Wasting Palsy is the capriciousness of its line of attack. Scarcely two instances are exactly alike in the combination of muscles implicated—hence an almost infinite variety of feature; yet there are certain more common combinations.

Among the most common cases are those in which the disease is confined to the hands, or to the hands and forearms. Not uncommon, likewise, are the cases in which the shoulder and upper arm of one or both sides are atrophied, while the forearms and hands remain healthy.

Coincidently with the loss of substance in the muscular masses, there is necessarily a corresponding loss of power. Certain less constant symptoms also sometimes make their appearance—namely, fibrillary tremors, cramps, twitches, and diminution of electric contractility in the muscles.

The loss of power corresponds, in the typical cases, very exactly to the grade of muscular atrophy, and gradually proceeds as the muscles diminish in bulk. In extreme cases absolute immobility of the limb, or part, is at length produced; more commonly the various movements are still capable of being performed, but with greatly diminished force. Not unfrequently, however, this correspondence is not exact; and the loss of power exceeds, more or less considerably, what is due to mere atrophy of the muscular fibres.
During the active stage of the disease the affected muscles sometimes exhibit curious vibratile tremors—fugitive wavy oscillations of the muscular fibres—which are visible under the skin, but do not produce any movement of the limb, nor are they sensible to the patient. When absent, they may occasionally be evoked by stripping the part or filling the skin. These vibrations are sometimes the earliest symptom of a new advance of the disease into parts not yet affected. They disappear altogether when the atrophy has reached an extreme degree, or when its progress has been arrested.

In uncomplicated cases the muscles of the wasting members respond to the electric stimulus readily, and with a force corresponding to their bulk. As a rule, there is no alteration in the tactile sensibility of the affected limbs; but in rare cases there is a slight numbness of the skin, and not unfrequently the parts are highly sensitive to impressions of cold. In about half the cases there is more or less pain of a neuralgic character in the course of the nerves leading to the diseased muscles, or in the neighbourhood of the muscles themselves. In some cases pain of an agonizing character is a marked feature of the complaint.

The general health is usually quite unaffected, the intelligence is clear, and the functions of organic life are performed with their usual regularity, so long as the muscles of deglutition and respiration are spared.

Course and Duration.—The course of Wasting Palsy is essentially chronic, and its duration uncertain. After destroying a certain group of muscles it may be permanently arrested, or it may proceed step by step until nearly all the voluntary muscles are disabled. The atrophied muscles may be again restored by therapeutical means to their original bulk: this is unfortunately not a very common termination—more commonly the wasted parts are crippled for the remainder of life. When the disease is progressive, its advance is seldom continuous, but is rather marked by repeated pauses and recommencements. The pauses may extend over a few weeks or months, or even several years. In a case now under my care in the Manchester Infirmary, the disease has started afresh in great intensity, after complete arrest for five years. In twenty-eight cases in which I was able to ascertain the continuance of the active process, the mean duration was thirty-eight months. Of these, four ended in recovery, thirteen in permanent arrest, and eleven in death. The cases which ended in recovery had a mean duration of fourteen months, those ending in arrest a mean duration of twenty-seven months, and those ending in death averaged a duration of more than five years.

Cases which could be traced to the effects of over-exercise of the muscles, were nearly always found to terminate in permanent arrest after the destruction of one or more groups of muscles; whereas cases which appeared to have arisen from exposure to cold, or from hereditary predisposition, showed a more decided tendency to a progressive course and a fatal termination.
WASTING Palsy.

Diagnosis.—The partial form is liable to be confounded with paralysis from injury to a motor nerve, lead palsy, and malarious palsy. In all these there is a marked atrophy of the muscles; and the affection may be confined to a narrow region, around which are healthy muscles, offering a strong contrast to the decayed ones.

Atrophy, resulting from injury to a nerve, is distinguished by the exact limitation of the wasting to the parts supplied by that nerve; also, if the nerve be a mixed one, there is, or was, an accompanying loss of sensation.

In lead palsy there is a comparatively sudden invasion: in a day or two—a week, or a fortnight, at most—the paralysis is at its height; whereas, in wasting palsy the loss of power is excessively gradual. The precursory or concomitant phenomena, distinctive of lead poisoning, seldom or never altogether fail—namely, colic, blue line on the gums, tremblings, pallor, and other symptoms of saturnine cachexia. Duchenne states, that the electric contractility of the muscles is markedly diminished or altogether lost in lead palsy; whereas, in Wasting Palsy, the muscles respond to the electric stimulus in a degree proportionate to their bulk. It will also be remembered that in saturnine poisoning the atrophy is distinctly sequential to the paralysis.

From ordinary general paralysis of central origin, Wasting Palsy is distinguished by the dissecting character of its march. It attacks the muscles in separate groups—in detail, as it were—and does not diffuse its ravages uniformly over extensive regions, or the entire body. It is very rare also that in general paralysis the wasting of the muscular masses bears any proportion to the loss of power.

Extreme muscular atrophy sometimes follows infantile paralysis, and the distribution of the disease may resemble that of Wasting Palsy, and produce ultimate results indistinguishable therefrom. The cases are, however, totally different in their history. Infantile paralysis has always a sudden invasion, and the wasting is subsequent to the loss of power.

Morbid Anatomy.—The essential changes found in the bodies of persons who have died from Wasting Palsy are confined to the muscles, the spinal cord, and the nerves.

The muscles of the affected regions are found wasted in various degrees. Some are only slightly atrophied, others more profoundly; while others again are reduced to pale, thin, membranous strata, or are altogether destroyed, and can only be identified by comparing the origins and insertions of certain fibro-cellular bands, which are the vestigial representatives of the previously existing muscular masses. The colour of the wasted muscles is changed to a pale red or rose, sometimes with a buff or ochreous tinge, and not unfrequently streaks of adipose tissue run, in lines, between the fibres. Where there is much fatty change, the wasting, which is so conspicuous a characteristic of the disease, is less marked; sometimes even the muscles are almost undiminished in bulk, but are transformed into masses of fat. This peculiarity has been observed only in the lower extremities.
The difference in the degree of atrophy undergone by adjoining muscles, and sometimes even by different parts of the same muscle, is very remarkable. Scarcely any two muscles are affected in an equal degree. Side by side with a pale, almost filamentous remnant, may be found a muscle of full red colour and undiminished bulk. One or two fasciculi of an affected muscle may survive in vigour after the total destruction of the remainder.

The decayed muscles have been examined microscopically by Meryon, Galliet, Oppenheimer, Virchow, and others. Meryon describes the primitive fibres as completely destroyed, the sarcomuscular elements being diffused, and, in many places, converted into oil globules and granular matter; whilst the sarcolemma was broken down and destroyed. Galliet, who examined the muscles in one of Cruveilhier's cases, states that in those parts of the muscle which had retained a rosy hue, the primitive fibres had preserved their strie tolerably distinct, and between the striae were seen fine grey or brilliant molecules, resembling fat. In the completely decolorized parts—those which to the naked eye appeared of a straw tint—there could still be recognised long cylinders, representing the primitive fibres. The sarcolemma was preserved, but the contained substance had lost its striated character, and was replaced by a uniform granular mass, presenting numerous minute grey molecules mixed with fatty granules. In parts where the disease was still further advanced, the granular matter and its enveloping sarcolemma had entirely disappeared, and there remained only the fibro-cellular framework of the muscle, destitute of any true sarcomuscular tissue.

The condition of the spinal cord and of the spinal nerves has been examined in some thirty-five cases, of which thirty-four have been tabulated by Bergmann.* The results of the investigations have not been by any means uniform. In sixteen cases the cord and the nerves were pronounced healthy, and in six of these the parts were examined microscopically. In six cases the cord itself was found healthy, but there was marked atrophy of the anterior roots of a certain number of spinal nerves. In one case both the spinal cord and nerves were healthy, but there existed disease of the medulla oblongata. In six cases the cord was found diseased when examined microscopically, though it appeared sound, or nearly so, to the naked eye. Lastly, in seven cases the cord appeared to the unaided senses palpably softened and disorganized.

Atrophy of the anterior roots was first noticed by Cruveilhier, and was supposed by him to supply the key to the pathology of this disease. He thus describes the condition of these structures in the body of the showman Lecompte, who died from general Wasting Palsy of five years' duration. "The anterior roots of the spinal nerves are remarkably small compared with the posterior, and this inferiority of size is particularly great in the cervical region. The proportion between the two roots had become greatly changed. According to my

observations, in the normal state, the posterior roots compare with the anterior, in the cervical region, as three to one; in the dorsal region, as one and a half to one; and in the lumbar region, as two to one. But here the proportion was as ten to one in the cervical, five to one in the dorsal and lumbar regions. Further, by plunging the cord into dilute nitric acid, I was able to observe that a very large number of the anterior cervical rootlets had been completely reduced to their neurilemma, and appeared as grey filaments, which, searched with a strong lens, presented no trace of nervous tissue; while, on the other hand, the anterior roots in the dorsal and lumbar regions had only suffered atrophy by emaciation. I was unable to trace the grey nervous filaments, or those simply atrophied, beyond the point where the anterior root joins the posterior; but I was able to establish the existence of atrophy of the nerves as they were about to penetrate the muscles."* A similar atrophy of the anterior roots was found in ten other cases, either with or without discoverable disease of the corresponding regions of the cord. In the great majority of the cases, however, the anterior roots were not perceptibly atrophied, and this leads directly to the inference that such atrophy is not an essential feature of the morbid anatomy of Wasting Palsy.

The morbid anatomy of the spinal cord is confessedly a subject of great difficulty. Until recently only the coarser changes of consistency—softening or induration—were appreciated by pathologists; and even after the microscope had been brought in aid of the examination, it soon became apparent that very important changes in the structure of the cord might be overlooked, unless the observer possessed special skill and practice in this branch of inquiry. The positive results of Gull, Lockhart Clarke, and Luys, who may be regarded as experts in the examination of the spinal cord, throw considerable doubt on the trustworthiness of the negative results obtained by Meryon, Savory, Oppenheimer, Friedberg, and others, who failed to detect in the spinal cords of patients who had died from Wasting Palsy, any appreciable changes of structure.

Luys describes as follows the microscopical changes in the apparently sound cord of a man, aged fifty-seven years, who died of pneumonia, and who had been the subject of advanced atrophy of the muscles of the left hand and forearm. There was also slight atrophy of the muscles of the right hand. The loss of power had corresponded accurately with the degree of wasting. Five of the anterior roots coming off from the cervical enlargement of the cord were atrophied. The microscopic examination of the cord showed increase of the capillary vessels in the grey substance at the level of the atrophied roots. The walls of the vessels were thickened and surrounded with a granular deposit, which extended into the grey substance. In the anterior grey cornua, at the point of exit of the anterior roots, there was an absence of nerve-cells, which were replaced by granular deposit. Some of the nerve-cells of the anterior horns were in process

* Archives Générales. 1853.
of degeneration—brownish, and filled with dark granulations. These changes were found especially on the left side, and very slightly on the right side. The rest of the cord was healthy.*

Dr. Gull gives an account of a man, aged forty-nine years, who became the subject of Wasting Palsy after striking his head against a beam, whilst driving under an archway. Some months after this accident he began to suffer pain from the occiput down over the shoulders, and in about a year the muscles of the upper extremities began to waste. Three years after the accident he was admitted into Guy’s Hospital. He then presented a remarkable example of muscular atrophy, without actual paralysis. The upper extremities were principally affected. The extensors of the right hand, the muscles of the thumb, and the interossei were extremely wasted. The wrist dropped. The muscles of the shoulder and arm, including the pectoralis major and minor, were much wasted; but in a marked degree less so than those of the forearm and hand. Very slight diminution of sensation. He could still lift the arm over the head. The left arm was similarly affected, but less than the right, so far as muscular atrophy was concerned—but there was numbness through the whole arm down to the fingers, accompanied with severe neuralgic pains. The trapezii, serrati postici superiores, rhomboidei, and all the long muscles of the neck and back, were remarkably atrophied. The legs were wasted and weak, but the patient was able to walk. There was constipation and dribbling of the urine. He died with febrile symptoms and dyspnea.

Autopsy.—Sections of the cord examined with the naked eye gave no distinct evidence of disease. There was a slight yellowishness of the posterior columns, and increased vascularity and thickening of the pia mater covering them. In these columns, especially in the right one, abundance of granule-cells were discovered with the microscope. The exudation was greatest in the middle and lower third of the cervical enlargement. The grey matter was hyperemic. There was no exudation into its tissue, nor into the anterior columns. The ventricle of the cord was enlarged and distended with delicate granular nuclei.†

The limitation of structural changes in the cord to narrow tracts and spaces, with a healthy state of the intervening parts, and the absence of any alterations visible to the naked eye, are also strikingly illustrated in the case of Dr. P., whose spinal cord was subjected to an exhaustive examination by Mr. Lockhart Clarke.

Dr. P. æt. 65, engaged in literary pursuits, began to complain some five years before his death of neuralgic pains in the ball of the thumbs of both hands, which before long extended to the forearms and arms. After some months there was marked weakness and wasting of the muscles of the thumbs and index fingers, which also became bent inwards towards the palms. The loss of power and volume in the

† Guy’s Hospital Reports, 3d Series, vol. iv. p. 194.
muscles progressed steadily, accompanied with the most excruciating pains, until his death. The right hand and arm were more profoundly affected than the left. In the later periods of the disease the pains extended to the lower limbs. The right pupil was constantly larger than the left, but the movements of the two were normal.

The cerebellum, pons Varolii, medulla oblongata, and spinal cord, were hardened in dilute chromic acid, and sent to Mr. Lockhart Clarke. He found nothing unusual in the external aspect of the cord, neither were the anterior roots of its nerves, in any of the regions, smaller than usual to any appreciable extent. The interior of the cord, from the filum terminale through the whole of the lumbar and dorsal region, to the lower end of the cervical enlargement, presented no actual change of structure, either in the white or grey substance; but there was a considerable deposit of corpora amylacea round the central canal. In the cervical region, however, the case was different; for here there were decided evidences of morbid changes of structure in the posterior grey substance. These structural changes extended in a variable degree from the lower end of the cervical enlargement upwards to the third cervical nerves: they were more conspicuous at its upper than its lower part. Thin transverse sections of this part of the cord presented to the naked eye no appearance that would excite suspicion of any lesion whatever; for the morbid portions, although numerous, were small and isolated. Under a low magnifying power the posterior grey substance was seen to be interspersed with a number of unnaturally transparent streaks, patches, or spots, of different shapes and sizes. Some of these spots were seen to interrupt the course of certain nerve-fibres which extended from both the anterior and posterior cornua to the opposite side. In all the sections examined, it was around or at the side of the blood-vessels that the morbid appearances were most frequently found. The morbid spots were more numerous and extensive on the right side than on the left. The morbid spaces varied in shape, size, and relative position in the different sections. In some they appeared as mere fissures or cracks, which, under a low power, might have been considered as the result of accident, if they had not been so uniformly found in only one portion of the grey substance, and more on the one side than on the other. But when a sufficiently high power was employed, it became at once evident that they were not merely vacant spaces, but composed of a substance which differed entirely in its nature from that of the surrounding tissue. This substance had a delicate, transparent, and very finely-granular aspect. The granules were more closely aggregated toward the centre of the mass, but were generally so fine that they could not be distinctly seen under a magnifying power much less than 400 diameters. Sometimes at the edges of these morbid spaces there seemed to be a kind of transition or degeneration of the surrounding nerve-tissue into the granular substance of which they were composed. In some instances, the broken ends of nerve-fibres proceeding from the posterior roots were seen to project into the opposite sides of these

VOL. II.
spaces, across which there was strong reason to believe that they had once been continuous.

The morbid appearances gradually disappeared about the level of the third pair of cervical nerves; in the middle third of the cervical enlargement they appeared to be more extensive than elsewhere, and they disappeared on approaching the dorsal region. The sympathetic in the neck was also examined, and found normal.*

The peripheral distribution of the nerves to the wasted muscles was in some cases found unaltered; in other cases the nerves were found atrophied; and in one instance, examined by Frommann,† the nerves leading to the atrophied muscles contained fat molecules and granular pigment.

The sympathetic in the neck was found diseased in a case examined by Schneevoogt.‡ The ganglionic cord was found extensively affected with fatty degeneration. Two similar cases have more recently been communicated by Jacoud to the Société Médicale des Hôpitaux.§ On the other hand, the sympathetic, in two other cases, examined by Landry and Bayldon,|| was found perfectly healthy.

Pathology.—Although defective nutrition of the muscles, ending in degeneration and atrophy, is an invariable feature of Wasting Palsy, it is evident that something more is necessary to the conception of the disease as a nosological entity. Muscles may be atrophied under a variety of pathological conditions, which are essentially distinct. Muscles may waste from want of use, as is witnessed in limbs which are temporarily kept immovable by surgical appliances, or more permanently by ankylosis of the joints. A similar result follows severance of the connexion between a muscle and its nervous centres, especially its spinal centres: and, lastly, atrophy of muscle may follow metallic poisoning. In Wasting Palsy there is also muscular atrophy, and, so far as is known, the local changes are not essentially different from those occurring in the afore-mentioned cases; and yet how widely different is the clinical significance of the fact! In order, therefore, to obtain any clear idea of the pathology of Wasting Palsy, it is absolutely necessary to consider circumstances which are antecedent to the mere atrophy.

It must be borne in mind that the several vital endowments of a muscle may be struck with paralysis in their entirety, or singly, or in certain combinations. A muscle paralysed by a cerebral lesion loses its voluntary power, but it retains its reflex functions and its power of self-nutrition, and does not become atrophied. Other cases are known in which the peculiar "muscular sense" is lost, with preservation of all the contractile and nutritive endowments. In Wasting

* Beale's Archives of Medicine. 1861.
† Deutsche Klinik. 1857.
‡ Schmidt's Jahrb. 1857.
|| See Author's Essay, p. 163, and Beale's Archives, 1861, p. 11.
Palsy, the muscle preserves its voluntary and reflex contractility, its muscular sense, and its sensitiveness to the electric stimulus; but it loses its power of healthy nutrition, and becomes degenerated and atrophied.

Pathologically, Wasting Palsy may be defined as an atrophic degeneration of certain groups of muscles, independent of any antecedent loss of mobility, or of any metallic poisoning. But the question immediately arises, whether the morbid process is primarily in the muscle itself, or in some part of the nervous system which controls its functions.

The former opinion has been adopted by Aran, Duchenne, Friedberg, Dr. Meryon, and others; it was also advocated by the present writer in his Essay on the subject, published in 1858. It must, however, be admitted that the additional facts observed since that epoch have tended materially to weaken this opinion, and to give support to the view that the primary lesion in wasting palsy exists in the spinal cord, or, at least, in some part of the nervous system.

The principal arguments against a nervous origin of the complaint consisted in the failure to discover, in several of the earlier post-mortem examinations, any palpable alteration in the spinal cord; and, secondly, in the want of correspondence between the range of muscles affected and the distribution of the nervous trunks. With regard to the former point, the multiplication of post-mortem examinations has very greatly increased the proportion of cases in which a lesion was discovered in the nervous system, and very much strengthened the suspicion that the earlier observations, in which the spinal cord was pronounced to be healthy, were not altogether trustworthy: The researches of Luys and Lockhart Clarke have demonstrated that profound changes in the substance of the cord may exist in detached and very limited areas, which might very easily be overlooked, seeing that it is exceedingly difficult to examine every individual section of the cord with the requisite care. Mr. Lockhart Clarke, speaking on this point, very significantly observes:—"There may be very obscure structural changes in the grey substance of the cord, or perhaps only in the ganglia on the posterior roots of the nerves, that may affect the nutrition of the parts to which they are subservient, without interfering with the functions either of sensation or motion; and in cases where the lesions occur in small isolated spots, the limitation of disease to particular muscles, or even to particular fasciculi of any one muscle, could be explained, I think, by the particular nerve fibrils within the grey substance" (Beale's Archives, 1861, p. 21).

The opinion, also, seems to be steadily gaining ground, that the nutrition of the muscles is placed under the control of a special set of organic nerves, having upward connexions with the sympathetic ganglia and the cerebro-spinal axis, which are by no means identical with the central connexions of the motor nerve-fibres of the same muscles.

Assuming the existence of such nutritive centres, all the clinical...
phenomena of Wasting Palsy, and the various findings of the post-mortem examinations, admit of easy explanation on the supposition that these centres, or some of their ganglionic connexions, are the primary seat of the disease. And the numerous associations and complications of the disease can scarcely be accounted for on any other hypothesis. In considerably more than one-half of the cases now collected, and examined after death, actual disease was found in some part of the nervous system. This is a proportion which does not permit the assumption of a coincidence of two independent morbid processes. Some relation between the atrophy of the muscle, and the disease of the nervous system, must, I think, be admitted. Either it must be assumed that the disease of the muscle is capable of evoking disease of the corresponding nervous centre, or the converse. And although the former supposition is by no means a difficult one à priori, it stands on a very slender basis of fact. So far as I know, the only authenticated instance of the centripetal transmission of a morbid process along a nervous trunk, is atrophy of the optic trunks after destruction of the eye. With regard to the muscles, evidence of any such transmission has yet to be given; the observations hitherto made, indeed, tend the other way. Schiff,* who made resections both of mixed and of purely motor and sensory nerves, found no alteration in the central portions of the cut nerves even after the lapse of a year and three quarters. Türeck † also examined the central origins of the nerves and their vicinities, in withered and amputated limbs, without finding appreciable alteration therein. Nor are suppurative and cancerous affections of the muscles known to be capable of transmission along the nervous trunks to the nervous centres.

The etiological conditions of some cases of Wasting Palsy, and the collateral phenomena in others, point also very strongly to a nervous origin. Several of the cases were sequential to falls or blows on the neck, or were associated with morbid growths in the spinal canal. In several well-marked cases of Wasting Palsy, also, motor paralysis, of undoubted central origin, affecting either the atrophied muscles or some other parts, preceded the atrophy. A strong impression was made on my mind by a case of this kind which fell under my notice four years ago. A young man was affected with acute paralysis of the voluntary muscles of the upper and lower extremities, unaccompanied by any wasting, beyond what was due to general emaciation. After an almost total loss of motion for a period of three months, recovery set in, which, in the course of a few months, ended in complete restoration of the muscular power in all parts except the hands and feet. The muscles of these latter parts passed on to a state of characteristic atrophy, from which only partial recovery took place. Dumenil, Duchenne, and Trousseau have also published cases in which there existed motor paralysis of the tongue without atrophy, combined

† Zeitsch. der K. K. Gesellschaft der Aerzte in Wien. 1853.
WASTING PALSY.

with atrophy without paralysis (Wasting Palsy) of the upper extremities.* It is easy to conceive that a morbid process in the motor centres may extend by continuity of tissue to contiguous nutritive centres (supposing such to exist), or, conversely, that disease of the nutritive centres may implicate motor or sensory centres in their vicinity, and so produce complicated clinical phenomena, analogous to those above mentioned, and which on any other supposition are very difficult of rational explanation.

The case-history of Wasting Palsy is rich in combinations of this sort. In the pure, typical, uncomplicated cases—where atrophy of the muscles is unmixed with any degree of motor paralysis, or convulsive movements, or with numbness, or neuralgic pains—it may be assumed that the morbid process is strictly limited to the nutritive centres in the cord, or to their connexions in the sympathetic ganglia. In the complicated cases it may be assumed that the morbid process radiates into those contiguous parts of the cord which control motor and sensory functions. The question can only be finally elucidated by repeated accurate examinations of the spinal cord in complicated cases.

Prognosis.—Wasting Palsy must be counted among the most intractable diseases; and when it invades the muscles of the trunk, it almost always goes on—sometimes very slowly, sometimes more rapidly—to a fatal termination. In the partial forms—when permanent limitation of the disease to one or two members is established—life may be regarded as no longer menaced, but the usefulness of the limb, if the atrophy be complete, is hopelessly impaired. If remedial measures can be applied early, and persevered in, while the atrophy is still in progress, there is some prospect either that the advance of the disease may be permanently checked, or even that partial or perfect restoration of the injured muscles may be effected.

The gravity of the prognosis, in so far as the preservation of life is concerned, depends on the disease confining itself to the extremities, or extending its ravages to the muscles of the trunk. When the respiratory muscles are invaded, the fatal termination is not far distant.

The probability of the disease becoming generalized is greatest when the origin of it can be traced back to a hereditary predisposition. The same danger, though in a greatly inferior degree, is to be apprehended when the disease has arisen from cold, and when the lower limbs are the first attacked; also when the upper and lower limbs are both implicated. On the other hand, the prognosis is much more favourable when the disease is occasioned by overwork, and when it is confined to the hands and forearms.

The longer the atrophy has existed, the less is the prospect of recovery: if the disease has become stationary for a year or two, there is no chance of any considerable improvement in the condition of the muscles, but the danger to life has become comparatively small.

* Bergmann, loc. cit. p. 88.
Therapeutics.—In projecting the treatment of a case of Wasting Palsy, the first necessity is to ascertain, as accurately as possible, the etiological circumstances under which the disease has originated. The removal of these—supposing them to be still in operation—follows as a matter of course. Mercury and iodide of potassium have been employed with success in cases where the disease depended on a syphilitic taint. If the disease has arisen from overtasking any set of muscles, these must be allowed to remain at rest.

The direct treatment embraces the employment of hygienic means—(baths, methodical exercise, change of air, &c.)—and the employment of galvanism and frictions to the affected muscles. Remak strongly advocates the use of the constant galvanic current applied to the spinal cord—especially the cervical portion.

Thermal and sulphur baths have been highly recommended by a number of writers. Wetzlar has especially called attention to the beneficial effects of the waters of Aix-la-Chapelle. Cold baths are objectionable.

The most effective remedy in Wasting Palsy is, undoubtedly, galvanism. Numerous observations attest its value when applied locally to the affected muscles. After a very considerable experience of its employment, I am convinced that it very rarely fails of some good effect when perseveringly applied. This effect is too often temporary: too often also it is found difficult to keep up the treatment with the requisite regularity for a sufficient length of time. In some cases marked improvement in the power and bulk of the muscular masses was witnessed; in others, the disease, previously progressive, was brought to a standstill. In the case of a man, still under observation, suffering from atrophy of the muscles of the thighs and upper arms, and of the erectors spine, which had been steadily progressive for twelve months, the daily application of the secondary current arrested the disease completely. The arrest has now continued for more than six years.

Duchenne gives the following directions for the employment of galvanism:—"Every muscle ought to be Paradised in a special manner, according as it has suffered more or less in its electric contractility and nutrition. Thus, the more a muscle is atrophied and its contractility diminished, the longer it should be subjected to the stimulation, the more intense should be the current, and the more rapid its intermissions. And this strong current and quick intermissions are the more necessary, according as the sensibility of the muscle is more benumbed. But when the sensibility is seen to return, it is prudent to diminish the intermissions, and abate the intensity of the current, and even to abridge the number of sittings, lest there be provoked unmanageable neuralgia, and, which sometimes has arisen, inflammatory accidents. During the Faradic treatment, I have excited the muscular sensibility, as much as possible, by rapid intermissions, as much as I have found this the most effective means of reacting on the nutrition of the atrophied muscles. Sittings of too long duration.

Durin...
fatigue and even exhaust the muscles, just as forced exercise induces atrophy, instead, like moderate exercise, of favouring nutrition. I believe that no sitting should be protracted beyond ten or fifteen minutes, at the most. I rarely give more than one minute to each muscle. To prevent weariness, and a bruised feeling, that sometimes follows the application of electricity, I pass rapidly over the muscles, taking care to return to each of them several times during the same sitting, so as to leave a short interval of repose between each excitation.”

The secondary symptoms—cramps and neuralgic pains—are most effectually subdued by warm baths, temporary rest in bed, and anodynes. The hypodermic injection of morphia has, in my hands, been followed by the happiest effects in relieving the excruciating neuralgia which is not unfrequently associated with this disease. One of my patients, thus afflicted, is in the habit of having half a grain of morphia injected early in the morning, when the pains are severe. Such an injection enables him to pursue his employment through the day in comfort—a result which he fails to attain by any dose of the same remedy internally administered.

PARALYSIS AGITANS.

BY WILLIAM RUTHERFORD SANDERS, M.D., F.R.C.P.

SYNONYMS.—Paralysis tremens, tremula, jactitans, palpitans; Tremor artuum, T. coactus; Scelotyrbe festinans, seu Festinia (Sauvages); Synclonus tremor; S. Ballismus (Mason Good), Schüttelkrampf, Zittern; Tremblement sénile; Trémulence paralytique progressive; Chorea senilis, Ch. festinans; Pseudo-chorea, Pseudo-paralysis Agitans; Dystaxia Agitans; the Trembles, &c.; the Shaking Palsy (Parkinson).

DEFINITION.—Idiopathic Paralysis Agitans consists of involuntary tremulous or shaking motions of the limbs, head, or trunk of the body, which take place even when the parts are supported and unemployed. The voluntary movements are preserved, but their vigour is lessened in the affected parts. In certain, usually advanced, cases, there is a disturbance of equilibrium; most commonly a disposition to stoop, or bend the body forwards, and to pass, in locomotion, from a walking to a running pace. The senses and intellect are unimpaired.

The definition includes these principal characters: 1st, The shaking or tremors, of a spasmodic kind, which occur even when the parts are not in use (Tremor coactus, palpitatio, παλμος, agitatio, jactitatio, quassus); 2d, The diminished muscular power (Paralysis, paresis, pseudo-paralysis); 3d, The disturbed equilibrium, shown usually in the tendency to stoop and to move forwards with accelerated speed (Scelotyrbe festinans, festinatio, procursus). Of these characters the clonic tremors or shaking are the most constant and distinctive. The paralysis, on the other hand, is of a peculiar kind. As here employed the term does not mean cessation or interruption of voluntary motion, which, on the contrary, persists; but it is intended to designate both the imperfection of the movements, which results from the interference of the tremors, and also the impaired strength and the slowness of muscular action, which are usually observed in the tremulous parts. Some writers objecting to call this condition paralysis (a name apt to mislead), have spoken of it as "apparent but not real paralysis," or "paresis," or "pseudo-paralysis," or "dystaxia." Lastly, the disturbance of equilibrium does not always occur; it is often late in appearing, and it serves chiefly to mark a special form or an advanced stage of the affection. Nevertheless, in fully developed examples of Paralysis
Agitans, all these symptoms, the tremors, paralysis, forward stoop, and accelerating walk, are associated together; as Parkinson expressed it, there is a combination of Tremor coactus and Scelotyrbe festinans.*

Historical Notice.—From the definition, as explained, it will be apparent that the older descriptions of Paralysis Agitans are to be sought less in the history of palsies than in that of spasmodic nervous diseases. In fact, paralysis agitans has been overlooked principally from being confounded, 1st, with tremors in general; 2d, with chorea; 3d, with cases of motor palsy (hemi- or paraplegia) complicated with spasmodic and tremulous movements.

1st. As a symptom, tremors early attracted attention. They were briefly noticed by Hippocrates and Celsus, while by Galen and succeeding writers, their kinds, their causes, and their value as prognostic signs were fully discussed. At length, nosologists established the genus Tremor, dividing it into species, in some of which tremor was still regarded as a symptom merely, while in others it was recognised as a substantive or idiopathic disease. Accordingly, well-marked cases of simple paralysis agitans are found in many of the older authors,† by whom they are sometimes alluded to, sometimes described with graphic details, in illustration of the pathology of tremor or as examples of a distinct species of disease. Less notice was taken of the disposition to stoop and hasten onwards. The earliest mention of this curious symptom is probably made by Gaukius; it was first particularly described by Sauvages under the name of Scelotyrbe festinans. But Sauvages did not connect it with tremors; he, indeed, had seen only two cases of it. It is certain that the combination of persistent tremors and hurrying gait had not been recognised, and no adequate description of paralysis agitans existed previous to Parkinson's "Essay on the Shaking Palsy in 1817." His account still remains the standard authority. Succeeding authors have, in general, simply quoted it, or have (especially French writers) overlooked the disease altogether. Accordingly, although Parkinson drew attention to the imperfection of our knowledge, the original contributions made since his time have been few and fragmentary. A list of references will be found at the end of this article.

2d. In regard to the confusion of paralysis agitans with chorea, it must be remembered, that convulsive diseases have been imperfectly discriminated, owing partly to the difficulty of their pathology, partly to the superstitions with which they have been associated. The disease, now commonly called chorea, was not so named originally, nor was it confounded with true St. Vitus's dance; it was regarded merely as a kind of convulsion (motus convulsivus) or species of epilepsy (epilepsia gesticulatoria), till near the end of the 17th century.‡ About that period, Sydenham, in the brief description which fixed the characters of the disease, unfortunately named it "Chorea Sancti

* Parkinson seems to consider the festination as essential to paralysis agitans, but it cannot be so regarded.
† Sylvius, Bonet, Juncker, Van Swieten, Sauvages, &c.
‡ Roth.
Viti," a misnomer which it has since commonly retained, with the effect of confounding it with the dancing mania, from which it is quite distinct.* While older authors therefore may have described cases of paralysis agitans among the motus convulsivi extraordinarii (just as some authors have given definitions applicable to it under the name hieranosos),† it is only in recent times that paralysis agitans has been confounded with what is at present known as chorea. This confusion is due partly to a certain similarity in the diseases, partly to the unsettled state of medical nomenclature. Ordinary cases of the shaking malady are widely distinct from common chorea; but certain extreme forms occasion a violent irregularity of movement, resembling in a great degree the gesticulations of that disease; so much, that it has been proposed to regard paralysis agitans as a more intense form of chorea,‡ and cases of paralysis agitans have been recorded under the title St. Vitus’s dance.§ Some cases even exhibit a combination of paralysis agitans and chorea.|| Moreover, while the common gesticulatory chorea is well known, there are other rarer forms of irregular and uncontrollable spasmodic movements, as yet imperfectly studied and classified, to which the term chorea is usually applied; such are the rotatory or spinning-top chorea, the saltatio or leaping ague, malleatio, &c. In some respects, therefore, it is not altogether inappropriate to designate paralysis agitans as a species of abnormal chorea; hence some recent authors employ the terms chorea senilis and chorea festinans for Parkinson’s disease. The objection to such names is, that they tend to confound paralysis agitans with the ordinary St. Vitus’s dance, from which it is entirely different.

3d. Lastly, the term paralysis agitans or shaking palsy has been applied, both before Parkinson’s essay and since, to cases of ordinary motor paralysis (hemi- and paraplegia) complicated with tremors—a complication not uncommon both in diseases of the brain, and especially in certain cases of chronic myelitis and of locomotor ataxia. Etymologically the name of shaking palsy belongs perhaps to these, rather than to Parkinson’s disease, but time has consecrated his use of the term. Parkinson’s malady is Idiopathic paralysis agitans, in which the tremors or shaking are the chief and earliest symptom, and the paralysis entirely subordinate and peculiar, true hemi- or paraplegia being rare complications: while in the cerebral and spinal affections just referred to, the loss of motion (akinesia) or sensation (anæsthesia) is the main feature of disease, and the tremors and spasmodic agitations are only concomitants (i.e. the paralysis agitans is Symptomatic).

* Authors distinguish the common chorea of Sydenham as chorea minor, the dancing mania as chorea major, Choreomania or Tarantismus. By Chorea or St. Vitus’s dance, however, Sydenham’s disease is now always meant, the Tarantism from its rarity being left out of account.
† Linnæus, Gen. Morb. Upsal, 1763, p. 17, No. 144: Hiera nosos, Byting, Corporis agitatio, continua, indolens, convulsiva cum sensibilitate. Also Vogel and Macbride.

|| Maclachlan.
Hence the latter class of cases should be styled, not paralysis agitans, but hemi- or paraplegia, or spinal or cerebral disease \textit{complicated with paralysis agitans}: \textit{i.e.} with spasmodic tremors. This distinction, which is essential for the accurate definition of Parkinson's disease, has often been overlooked, and requires, therefore, to be specially insisted upon.

In the following description of Paralysis Agitans, besides some allusion to tremors generally, it is proposed for the sake of distinctness, to recognise certain subdivisions of the disease, which the experience accumulated since Parkinson's essay seems to require.

\textit{Divisions.}—Idiopathic Paralysis Agitans is divided into I. General (including the bilateral and unilateral), and II. Local.

I. General Idiopathic Paralysis Agitans presents certain forms or varieties important to distinguish, as regards prognosis and cure.

A. Senile forms. \textit{Paralysis Agitans senilis}, occurring in advanced life, above fifty or sixty; usually incurable and with fatal tendency from senile decay: divided into 1st, \textit{Simplex}, and 2d, \textit{Festinans} or \textit{Procursoria}. Varieties, \textit{Unilateralis Hemiplegica} and \textit{Retrograda}.

B. Non-senile forms, occurring under fifty, without fatal tendency, sometimes curable. 1st, \textit{Paralysis Agitans non senilis, simplex} (\textit{i.e.} sine festinatione), including also \textit{hysterical} and \textit{reflex} \textit{Paralysis Agitans}, \&c. 2d, \textit{Paralysis Agitans toxica}, including chiefly, tremblement métallique, mercurial palsy, \&c.

The curable forms have been supposed to be \textit{Functional}; the incurable, \textit{Organic}.

It will be necessary to describe the senile forms in detail, as they are much the most frequent; a shorter notice will suffice for the others.

\textit{Description.}—I. A. Idiopathic Paralysis Agitans senilis. 1st, \textit{Simplex}, when attended by the signs of senile decay only; 2d, festinans, or procursoria, \&c., when the disturbance of equilibrium is also present. These two forms will be described together.

\textit{Symptoms and Course.}—Onset usually gradual; course slow, progressive, liable to be arrested at different stages; duration protracted; associated with senile decay. Several stages may be recognised.

1st \textit{Stage. Commencement}.—The first symptoms are usually so insidious that the patient cannot tell precisely when they began. A sense of weakness, and a disposition to trembling is felt in some part, most frequently the hand or arm, sometimes the leg or head. The tremors, at first slight and occasional, gradually increase; and at an uncertain period, seldom less than a year, the corresponding parts of the opposite side, more rarely the other limb of the same side, become affected. The tremors and muscular debility seldom extend beyond the arms during the first two years, which period may be said to comprise the first stage. Except for the inconvenience arising from the unsteadiness of the hand in writing or other manipulation, the patient would not consider himself the subject of disease. At this period, probably, remedies might be applied with success. In a few
cases, instead of the ordinary gradual approach, the tremors have come on rapidly after a fright or exposure to cold.

2d Stage. Generalization of the Tremors.—Some time after the hands and arms have been affected, one of the legs, usually that on the side first attacked, begins to tremble and is more easily fatigued; and in a few months, the other leg becomes similarly tremulous and weak. Walking becomes a task requiring considerable attention. The legs feel heavy as lead, and are not raised to the height or with the promptitude which the will directs, so that care is necessary to prevent frequent falls. At a later period, usually some years after, the tremors extend to the head and finally to the whole body. The tremors of the limbs are usually in the direction of flexion and extension, sometimes of rotation, sometimes of ab- and adduction (so that patients have had their knees padded to prevent them knocking together). In the head and neck the movements are more commonly lateral (shaking negatively), then vertical (nodding). The lower jaw is affected with vertical, rarely lateral motions; and the tongue is tremulous, impeding speech; in many cases, however, these parts are not affected till near the end of the disease. The larynx is little, if at all, affected. Deglutition does not suffer till near the close. The muscles of the eyeballs and eyelids, and the facial muscles of expression, are nearly always exempt from tremors.* The thorax and trunk are later and less affected than the limbs, or head, or neck. Appearing chiefly during a general paroxysm of tremors, the spasmodic action of the respiratory muscles occasions a peculiar panting of the breathing and a jerking interruption of speech. As the tremors last, and become general over the body, they increase in intensity; from mere vibrations they become violent convulsive agitations. The limbs are jerked to and fro as if by the actions of springs or by rapid shocks of electricity.

From the beginning, and throughout the whole course of the disease, mental emotion or agitation excites an attack of tremors, or greatly aggravates them; rest and quietude diminish or stop them. In general, a slow, firm, voluntary act, or the grasp of a heavy body,† stops the tremors for a time, and any change of posture has the same effect, affording the patient considerable relief. Parkinson mentions an artist, who, while his arm and hand were palpitating strongly, would seize his pencil, with the effect of instantly suspending the tremors and allowing him to use it for a short period.‡ On the contrary, when the limbs are quiescent, a voluntary movement usually starts the tremors, which continue for some time afterwards. The attacks of tremors are at first of short duration, and separated by intervals of complete immunity; they become more severe and the intermissions shorter as the disease proceeds. In certain examples the

* In Oppolzer's remarkable case the tremors are reported to have extended to the muscles of the face; also in a few other cases.
† A patient we saw lately holds a smoothing iron to keep his hand still; another steadies it by seizing a chair.
‡ Lebert refers to a similar instance.
paroxysms have lasted so long as ten to forty minutes, and were followed by fatigue like that produced by violent muscular exercise." The tremors cease entirely during sleep.

Parkinson does not seem to have noticed that frequently, in addition to the tremors, there occur tonic spasms (rigidity or contraction) of the muscles in the parts affected. The fingers or toes or the whole limb become rigidly flexed or extended. These cramps last for some minutes, and return at intervals; they are sometimes painful and followed by a sense of fatigue. They occur chiefly during the day, but sometimes in the night also. In a case, recently observed by the writer, startings of the limbs took place during sleep, in the form of powerful flexion of the knees, by which the legs were suddenly drawn up. On the relaxation of the spasms, the limbs were slowly let down to their previous position without awakening the patient.

Local deformities also sometimes result. From the hands being kept constantly supported to stay the tremors, the fingers become dislocated backwards on the metacarpals so as to form an angle with the back of the hand.† Sometimes the distortion is lateral; in a case lately seen the fingers were bent obliquely to the radial side, owing probably to the clonic and tonic contractions being more powerful in that direction. These deformities must not be confounded with the effects of rheumatism.

3d Stage. Disturbance of Equilibrium.—The occurrence of this symptom is variable; sometimes it appears early, while the legs are becoming tremulous; sometimes it is deferred for ten or twelve years or more after the tremors; in many cases it is entirely absent (Paralysis Agitans simplex). It is therefore less a stage, than a peculiar feature characteristic of one form, or of a special extension of the disease; its presence should accordingly always be indicated by some additional term such as festinans, or procursoria.

Owing to deficient power in the extensor muscles of the back, the patient becomes less able to preserve the erect posture; he bends forwards while sitting, still more while standing. In walking, the centre of gravity being displaced forwards, while the legs can only be moved slowly, stiffly, and with some degree of spasmodic jerking and agitation, he is in constant danger of falling; he stumbles over small obstacles in his path, and by taking short, hurried steps, he is impelled from a walk to a run till he has difficulty in stopping himself. Persons in an early stage of this condition, can sometimes march slowly with long measured strides, quite well; but so soon as they resume their shuffling gait, they must quicken their pace to avoid falling. There is no vertigo as in cases of precipitancy from tumours or injuries of the cerebral peduncles, and adjoining parts. The forward running is the usual form of this curious symptom, which has not yet been much studied, but exceptional varieties occur. Thus Romberg met with an opposite disturbance of balance. "Two patients, aged sixty, felt a constant desire to walk or fall backwards, and therefore carried the

† Trousseau.
head strongly bent forwards; one of them, in order to stand, separated his legs widely, at the same time crossing his arms on the back, with the view of offering some resistance to the overpowering tendency to move backwards” (Paralysis Agitans Retrograda). Graves mentions a patient who had to be balanced to and fro before starting, and who, if arrested in his forward movement, immediately began to hurry backwards and could not stop himself. No case is recorded of a disposition to fall or move sideways.* There is a less degree of this symptom in which the patient stoops and shuffles in his walk, but has not the true festination.

4th Stage. Disease fully established.—When the tremors have become general, violent, and of frequent recurrence, the patient experiences great inconvenience, which increases with the progress of the disease. The limbs cannot execute the directions of the will in the common offices of life. The patient is unable to write or perform any manipulation: he cannot hold a book to read, and has the utmost difficulty or is quite unable to clothe or feed himself. Raising a glass of water to the lips is impossible; the fluid is spilled and the glass knocked to and fro against the mouth. Patients deprived of assistance, in order to allay their thirst, have lapped up fluids with the tongue, like the lower animals. It is painful to witness the struggles which the patient makes to control the agitation of his body and effect some desired movement; the more he tries the more extravagant the jactitations become. To increase his distress, paroxysms of tremors now often arise during rest; indeed, at times, the tremors become almost constant, with frequent aggravations. Commencing for instance in one arm, the wearisome agitation is borne until beyond suffering, when by suddenly changing the posture it is for a time stopped in that limb, but commences generally in less than a minute in one of the legs or in the arm of the other side, often spreading over the whole body. Harassed by the tormenting round, the patient has recourse to walking, to which he is partial, both on account of the relief afforded by change of posture and because his attention is diverted from his unpleasant feelings by the care and exertion required for its performance. But if the procursive tendency has appeared, this relief is denied. The propensity to lean forward becomes invincible. Forced to step on the toes and fore part of the feet, while the upper part of the body is thrown forwards, he is irresistibly impelled to take quick and short steps, and to adopt unwillingly a running pace in order to avoid falling upon the face.† On some days, however, the tremors are less severe; and the patient is always relieved by intermissions during the day and complete cessation of the tremors during the night. The disease, even

* Sauvages relates of a painter, aged 50, that he was not only impelled forward in walking, but could not turn to right or left till he stopped himself against an obstacle, supported by which he turned his body gradually round and then hurried straight on anew. This is given as Scelotyrb festinans, without any mention of tremors; but similar conditions have been observed in paralysis agitans.

† In the words of Trousseau, “Il s’en va trotillant, sautillant,—il est obligé de courir, pour ainsi dire, après lui-même.”
at this stage, sometimes undergoes remissions for some weeks or months, during which the tremors greatly abate; unfortunately a relapse occurs and the disease resumes its progressive course.

5th Advanced and Final Stages.—Hitherto the jactitations have been suspended at intervals during the day, and have ceased entirely at night. But in this stage tremors of the limbs occur even during sleep, and increase till they awaken the patient, often with much mental agitation and alarm. In addition, signs of failing strength and physical decay which had previously appeared, rapidly increase. Unable to convey food to the mouth, the patient must be entirely fed by others. The bowels, previously torpid, require powerful stimulating medicine or mechanical aid for their relief. The trunk becomes permanently bowed, and the whole muscular power fails. The patient walks with great difficulty; a stick no longer suffices; he requires an attendant, who, walking backwards before him, prevents his falling forward by the pressure of his hands against the fore part of his shoulders. His words are scarcely intelligible, and the memory and intellect are weakened. The actions of the tongue and pharynx are so hindered by enfeebled action and perpetual agitation, that the food can hardly be masticated or swallowed; the saliva mixed with particles of food continually drains from the mouth.

Finally, amid increasing general debility and diminished voluntary power, the tremors become more vehement, and seldom cease for a moment. When exhausted nature seizes a small portion of sleep, the motions become so violent as to shake the bed-hangings, and even the floor and sashes of the room. The chin is bent down upon the sternum; the power of articulation is lost; the slops with which he is fed trickle continually from the mouth. The urine and feces are passed involuntarily; bed-sores form; and at the last constant sleepiness, and other marks of extreme exhaustion, usher in the fatal termination.

The senile forms of the Paralysis Agitans, as just described after Parkinson, represent, it should be observed, the most aggravated examples of the disease. And the subjects of it being advanced in years, the effects of senile decay are necessarily mixed up with the other symptoms. Indeed this kind of Paralysis Agitans seems to induce and to terminate in general failure of the system. But the course of the senile disease is not always so deplorable. Many cases of the simple or non-procursive form remain stationary for an indefinite period, and never reach the ultimate stages.* A few exceptional cases have even been cured. The procursive Paralysis Agitans also occasionally exhibits an arrestment, or, at least, extreme protrac-

* Dr. Maclachlan, out of a large number of instances among the inmates of Chelsea Hospital, found that the affection often had little or no influence in shortening life. None of his cases had occurred below 55, the majority between 65 and 70, yet in many the disease lasted upwards of 30 years. An in-pensioner, in his 107th year, had been affected since he was 60.—P. 213.
tion of its course. The fatal forms seldom occupy less than ten years. At the same time, Parkinson's account, drawn directly from nature, represents without exaggeration, the slow, continual progress, and the fatal results of the senile paralysis agitans in its full development.

One very important fact, observed in nearly all cases of Paralysis Agitans, is that the cutaneous sensibility is not affected, either in regard to pain, touch, or temperature. The sensory powers, indeed, persist remarkably even amid the general failure of nervous energy in the later stages of the disease.

The Unilateral* or "Hemiplegic" variety of Paralysis Agitans, first noticed by Marshall Hall, presents no essential difference from the bilateral (paraplegic) disease, just described. The limbs on one side are agitated with violent chronic tremors, while those on the opposite side are entirely unaffected, or exhibit only a slight and occasional tendency to tremble. The affection is not less severe than the bilateral into which it probably passes. There is no complete case of this form, from beginning to end, on record. In one instance, lately under observation,† there was no disturbance of equilibrium, no festination, and it does not appear that this symptom has been met with in the unilateral disease. The prognosis is, probably, the same as in the other senile forms.

To sum up: Paralysis Agitans senilis occurs in advanced life, past fifty, usually past sixty years of age; it is combined with and appears to hasten senile decay. Two forms of it are distinguished, the Simple and the Procursive (festination): it is usually very protracted, lasting ten years or more, and is, with rare exceptions, incurable.

We pass now to those forms of the disease which occur earlier in life.

I. B. Non-senile forms of Paralysis Agitans, occurring under fifty, without fatal tendency, and sometimes admitting of cure. They are much rarer than the senile forms of the disease.

1st. Paralysis Agitans Simplex, non-senilis (sine festinatione).—This form resembles the senile disease in regard to the tremors, differing chiefly by the absence of the signs of senile decay. The jactitations affect the same parts, the limbs, head, and trunk, exempting the muscles of the eyeball, and usually also the facial muscles of expression.‡ They come on in paroxysms excited by attempts at voluntary movements, or by mental emotion; they subside or disappear during rest, and they cease entirely during sleep. In severe cases, they are extremely violent. The limbs and the whole body quiver and shake convul-

* "Uni-" and "Bi-lateral" are preferable to "Hemi-" and "Para-plegic," being less apt to lead to confusion with ordinary motor paralysis.
† Patient of Dr. Warburton Begbie, to whom the writer is indebted for an opportunity of examining it.
‡ Marshall Hall mentions a male, aged 28, with paralysis agitans of right arm and leg, who presented a "peculiar rocking motion of the eyes, and a degree of stammering and defective articulation." Certainly, however, tremors of the oculo-motor muscles are very rare in paralysis agitans; singularly so since Nystagmus by itself is not uncommon.
PARALYSIS AGITANS.

sively in the most extravagant manner. The patient cannot stand without support; in walking he jerks and staggers as if moved by broken springs, and is like to be pitched to the ground at every step. He cannot dress or feed himself; if his limbs are approximated, they knock against each other; and if his hand is brought near the chest or the face, it strikes upon them in a series of quickly repeated blows. When the shaking arises unexpectedly, the patient may hurt himself, knocking his head against a wall, &c. It is rare, however, for the tremors to exhibit such extreme vehemence; more commonly they exist only to the extent of rendering the execution of regular movements impossible, interfering completely with the patient's usefulness. It is further observed that, although sometimes as severe, or more so than in the senile forms, the tremors are less continuous and never occur during sleep, although they may come on as soon as the patient awakes or turns in bed. The special distinctions of the non-senile Paralysis Agitans are therefore: 1st. There is no disturbed equilibriun; no disposition to fall or hasten forwards or backwards.* 2d. The diminution of voluntary muscular power is slight; sometimes none is observable. Tested by the grasp of the hand, by the dynamometer, or by the ability to lift weights or bear burdens, the muscular force is often found equal to the normal standard; sometimes the shaking arm appears stronger than the sound one. Yet the patient himself usually complains of diminished strength, and he has less ability to sustain prolonged exertion. If the disease progresses the muscular debility increases. This is an important sign, for increasing muscular weakness is of unfavourable prognosis. 3d. There is no fatal tendency. The affection is extremely obstinate, often incurable, but the general bodily health is not impaired, and the duration is indefinite if no complication supervene. A patient, lately seen, aged sixty-six, was first affected at twelve years of age; the tremors have entirely unfitted him for labour during nearly his whole life; yet even now his appetite and bodily health are excellent. Similar cases are not very rare; but being regarded as examples of incurable infirmity,† they are not brought under the notice of the physician, and probably suffer irremediably from neglect of care at the earlier stages. 4th. Occurring in middle life (twenty-five to fifty), however formidable in appearance, it is susceptible of amelioration, and sometimes of cure. A case was cured by Elliotson by the use of the carbonate of iron (1827), and several examples of recovery have been recorded under different methods of treatment.‡ Others, however, have resisted treatment

* At least no case of non-senile Paralysis Agitans, accompanied by festination, is known to the writer.
† Often objects of charity, or paupers in or out of workhouses. The disease, however, affects the rich as well as the poor.
‡ Trousseau, case of St. Vitus's dance (properly Paralysis Agitans) in 1843; Russell Reynolds, Handfield Jones, Sanders, case of dystaxis or Pseudo-paralysis Agitans. This patient, after a year, was able to return to light work, the tremors having nearly ceased. Dr. Alexander Turnbull, R.N. has recently communicated to the writer two cases which came on after ague at Panama—the one recovered after a year, the other was still under treatment.

VOL. II.
altogether. To account for the fact that some cases are curable while others are not, it has been supposed that the former are functional and the latter organic.

To the slighter and more curable forms of paralysis agitans, belong the 
Hysterical Paralysis Agitans, which exhibits the usual tremors (sometimes an approach to the festination), and is accompanied by hysterical symptoms and usually some disorder of the general health. Though often obstinate, it is entirely free from danger, and is usually cured when the general hysterical condition is removed by judicious treatment.

The Intermittent Paralysis Agitans, in which tremors of the limbs, lasting five to six minutes, recur twice or thrice in an hour, appears frequently to depend on intestinal worms in young subjects, or is a variety of the hysterical or reflex forms. It is curable.*

Reflex Paralysis Agitans may depend upon disordered primæ viæ, and be cured by appropriate remedies (Sauvages, Tremor a saburrâ). Perhaps derangements of other internal organs may exert a similar effect; as also external wounds and injuries. An interesting case, caused by the latter, was observed by Dr. Door, and related by Dr. Haas (1852). A healthy girl of nineteen received a splinter under the nail of her right thumb, on the extraction of which violent pain, and soon after paralysis agitans, came on in the right leg, subsequently spreading to the right arm and the whole body. The tongue and speech became affected; the general health suffered; the face had a stupid expression, and she dragged the legs in walking. She recovered completely.

Lastly, it appears from the important cases described by Dr. Hennis Green (a few similar to which are mentioned in older authors) that nervous tremor of the nature of Paralysis Agitans may occur in children (age, eleven to thirteen), and is in them speedily curable. Of the three cases which he reports, two recovered in about a month; the third died of pulmonary consumption, and no trace of lesion was found in the brain and spinal cord.

The non-senile paralysis agitans is particularly apt to be mistaken for chorea; it sometimes assumes the unilateral form.

2d. Paralysis Agitans Toxica.—Various poisons occasion debility and tremors. When these symptoms arise from the abuse of alcohol, tea, coffee, tobacco, or opium, they rarely occur except when the parts are used, and hence are simple tremors only; but if they take place also during repose, they belong to this sort of paralysis agitans. A strongly marked and very characteristic form of the curable paralysis agitans is brought on by inhaling fumes of mercury, and, though less frequently, by certain other metallic poisons (tremor metallurgorum—tremblement mercuriel). This will be described elsewhere. (See Tremblement Métallique.)

The other kinds of tremor mentioned by medical writers, are either unimportant or symptomatic of other diseases; they present an in-

* See Gowry’s case.
terest, as related pathologically to the morbid condition probably existing in idiopathic paralysis agitans. Such are the tremors from bodily weakness and mental emotion: tremor-senilis, which is evidently closely allied to and may pass into paralysis agitans senilis; febrile tremors and rigors (attended by a sense of cold, which is never present in paralysis agitans), analogous probably to the toxic forms of paralysis agitans; tremor or subsultus tendinum, which exhibits the same spasmodic jerking of the muscles as paralysis agitans; lastly, the tremors in diseases of the brain and spinal cord (hydrocephalus, parasites in cerebrum, myelitis, ataxia, tumours, &c.), are symptomatic and, as previously explained, distinct from idiopathic paralysis agitans.

II. Local Paralysis Agitans attacks a single part, most frequently the head and neck, or the arm, or the lower jaw, and remains limited to the region affected. The tremors occur occasionally, seldom constantly, during the day; they cease at night; they are excited or aggravated by exertion or emotion. Usually free from danger, local paralysis agitans is regarded, like the spasmodic tics, as an infirmity or bad habit rather than a disease. It is at the same time very obstinate, in fact usually incurable. It is important to distinguish the idiopathic paralysis agitans which continues local from that which is the precursor of the progressive general disease, or which may be symptomatic of a tumour or other lesion of the nerve centres. At first the distinction may be impossible; but the history and course of the affection determines the diagnosis. Whenever the tremor has continued for some time unattended by any concurrent serious symptoms and strictly confined to one part, experience warrants the conviction that the morbid action has been exhausted in a circumscribed area, and that no extension of the disease need be feared. It is, indeed, singular that after a few years the local exhibits no tendency to pass into the general disease.

A few remarkable cases have occurred of paralysis agitans restricted to the lower jaw and tongue; in some distressing instances all remedies proved unavailing. The pathology has not been ascertained, and probably the severer cases were not idiopathic, but were symptomatic of some grave disease of the nerve centres. Of the latter kind an interesting case is recorded recently by Leyden, in which paralysis agitans of the right arm was found associated with sarcoma in the left optic thalamus. The more serious symptomatic kinds are distinguished from the idiopathic by the more dangerous character of the symptoms, among which are the signs of centric nervous lesion, such as motor and sensory paralysis, &c. In respect of pathology and treatment, the local resembles the general paralysis agitans.

CAUSES.—These are frequently obscure, but it is probable that conditions productive of debility or atrophy of the motor nerve centres occasion the idiopathic paralysis agitans. The results of experience are as follows. Predisposing Causes.—1. Age is of primary importance,
both in causing the disease and aggravating it. 2. Hereditary and parental influence is indicated in some cases.* 3. The male sex is almost exclusively the subject of general paralysis agitans; the hysterical forms and local tremors of the head being met with in the female. 

Exciting Causes.—1. Violent muscular exertion is a frequent cause, as also—2. Injuries, especially falls; also wounds, &c. 3. Excessive mental exertion, and particularly—4. Violent emotions, as terror or fright, which have sometimes produced the disease suddenly. 5. Venereal excesses have been alleged. 6. Exposure to cold and wet, as lying on damp ground, especially when giving rise to—7. Rheumatism, which was noted by Parkinson, and has a decided causal relation to paralysis agitans; also—8. Ague.† In certain cases paralysis agitans appears to have followed—9. Fever (typhoid and various exanthemata) and—10. Syphilis. 11. Intestinal worms sometimes give rise to it in young subjects, occasionally modified into a periodic or intermittent type. 12. Disordered primeae æ (tremor a saburrâ). 13. Suppressed itch will hardly now be admitted.‡ 14. Alcohol, opium, tobacco. 15. Certain poisons, particularly mercurial vapours, cause the paralysis agitans toxica. While these are the causes of the idiopathic disease, the symptomatic paralysis agitans, as already stated, may occur, combined with other characteristic signs of nervous disease, in various lesions and tumours, &c., of the brain and spinal cord.

Diagnosis.—Idiopathic paralysis agitans is sufficiently characterised to be of easy recognition; but its relations to allied affections are important. 1st. It is distinguished from the other species of the class tremors, because in paralysis agitans the trembling occurs not only during action, but even when the parts are not in use and are supported (spasmodic, tremor coactus). Tremor senilis, which most resembles it, may pass into paralysis agitans, when the tremors which begin during action continue after it has ceased; the tremors usually at the same time increase in intensity from trembling to jactitation. 2d. The different kinds of paralysis agitans are distinguished: the simple senile form by occurring in advanced life, by its progressive course, association with general decay of the system, and fatal issue; the procursive (festinans) senile form presents in addition the disturbed balance in locomotion; the simple non-senile form occurs in middle age or under, is often stationary in its progress, may be ameliorated or cured, and is not accompanied by disordered equilibrium; the hysterical, remittent, reflex forms, and that occurring in children, &c., are known by their special circumstances; the Toxæ Paralysis Agitans is recognised by the cause, and by the concomitant effects of the

* Sauvages. "Mulier gravida, que maritum subito peremptum exhorruerat, genuit filium tremore miserando correpsum." Most knew a whole family in which it was hereditary. Lebert refers to females who, in successive generations, being otherwise in good health, presented tremors of the head at the cliamaeterie age.

† Romberg, Maclachlan, Turnbull. No relation to gout has been alleged.

‡ Mentioned by Canstatt.
poison; in the mercurial tremors the tongue and mouth are usually and early attacked, which is not the case in ordinary paralysis agitans. 3d. The relations to common chorea, both of difference and resemblance, are instructive. Chorea occurs chiefly in the young before puberty; paralysis agitans attacks the middle-aged, and especially the old. The gesticulations in chorea are jerking, irregular movements, changing frequently, and dissimilar on the two sides; the tremors or jactitations in paralysis agitans consist of to-and-fro oscillations of the part, due to the brief alternate action of antagonist muscles; they continue long unchanged, and are usually the same on the two sides. Chorea specially attacks the female, paralysis agitans the male sex. With attention, therefore, the diseases are not difficult to distinguish. But their points of resemblance are striking. Both consist of involuntary, spasmatic movements, rapidly repeated, and not under the control of the will, while the voluntary motor power persists in the affected parts, although it is often enfeebled, the debility sometimes amounting to paralysis.* Both are often caused by fright, and by rheumatism (although no relation seems to exist between paralysis agitans and heart disease); in both, when fatal, no visible lesion may be discovered. On the other hand, chorea is nearly always curable in a comparatively short period; while paralysis agitans, although susceptible of cure in younger individuals, is a peculiarly obstinate disease, and is incurable in old persons, in whom it associates itself with senile decay. 4th. The irresistible movements forward or backward in paralysis agitans present great affinity to the like symptoms met with in "leaping ague," and certain forms of Tarantism and abnormal chorea, and which are also observed in connexion with lesion of the cerebral peduncles or other parts of the encephalon.† But these affections are not usually attended by tremors, and the history and special concomitant symptoms are sufficiently distinctive. The difference of Symptomatic from Idiopathic Paralysis Agitans must always be kept in view. 5. The same remarks apply to the discrimination of idiopathic paralysis agitans from certain cases of locomotor ataxia and chronic myelitis, &c.—affections which it often closely resembles in the progressive character of the symptoms, and in the spasmodic nature of the movements. But these spinal diseases are, in addition to their clinical history, especially distinguished by the presence of decided motor, and mostly also of sensory paralysis; while in idiopathic paralysis agitans, the sensibility is remarkably exempted, what is there called paralysis being only a failure of vigour. The diagnosis is very important, and only difficult because the occurrence of tremors as a complication in various organic nervous diseases may mislead, if

* Both are sometimes unilateral.
† Marshall Hall remarks the similarity of certain symptoms in Paralysis Agitans to the effects observed by Serres in diseases of the tuber annulare and tubercula quadrigemina. The irresistible movements—forward, backward, lateral, whirling, rolling, somersault, &c.—in experimental lesions of the brain in animals (Fodera, Magendie, Flourens, &c.) have thrown much light on the subject.
the difference of Symptomatic from Idiopathic Paralysis Agitans be not attended to. 6. In a similar manner, Paralysis Agitans is distinguished from Beriberi, Raphania, &c.

Complications.—These are rare in Idiopathic Paralysis Agitans; the health usually continuing good till senile decay begins. Apoplexy, hemi- and para-plegia sometimes occur, but not often. Common chorea has, in some cases, been found associated with paralysis agitans;* usually, however, the disordered movements, called chorea, have been only exaggerated examples of the shaking disease. On the other hand, as already remarked, Symptomatic Paralysis Agitans may complicate many diseases of the brain and spinal cord.

Pathology and Morbid Anatomy.—Tremors are generally admitted to be a sign of weakness in the nerve centres, and are ascribed to defective and interrupted discharge of nervous stimulus. But two kinds of tremors have been distinguished,† first, simple or passive tremors, which occur during a voluntary act, and cease with it, being evidently due to want of power only (τρόμος); second, spasmodic, clonic, or active tremors which take place even during rest when the parts are supported and unemployed (παλμός, tremor coactus, palpitation): these are short, alternate, clonic convulsions of antagonist muscles, and imply some irritation in the motor nerve centres. Although these two kinds are allied and pass the one into the other, yet the distinction is important, and furnishes the ground of diagnosis; the spasmodic, not the passive tremor being characteristic of paralysis agitans. The disturbance of equilibrium is no doubt owing to an affection of a different part of the nervous system from the tremors, since these may exist, even generalized, without it. The cerebral or cerebellar peduncles, or the pons varolii, are most probably the seat of lesion. But while the locality is different, the association with tremors shows that the morbid action is probably the same in both. The general opinion is that the tremors are due to an affection of the spinal cord, the disturbed equilibrium to an extension of the morbid action within the cranium. Hence some writers speak of Paralysis Agitans Spinalis, consisting of tremor and muscular debility, and Paralysis Agitans Cerebralis, in which the disturbance of equilibrium is superadded.‡ There is no vertigo nor distortion of the eyeballs, as in lesion of the base of the encephalon. The disturbed equilibrium seems due to weakness of one set of muscles (e.g. extensors) and perhaps spasmodic action of their antagonists (i.e. flexors).

Morbid Anatomy, which formerly gave only negative, has lately afforded indications of positive results. The facts are as follows:—

1st. In many instances of Idiopathic Paralysis Agitans, no lesion of the cerebro-spinal axis can be discovered by our present means of

* Maclachlan, p. 216.
† Distinction first clearly drawn by Sylviius, previously indicated by Galen.
‡ Remak.
PARALYSIS AGITANS. 199

**investigation. In these cases, therefore, the disease may be regarded as functional or dynamical;** and it may be presumed to depend, (a) on impaired generation of nerve energy, due to some unknown conditions; (b) alteration of vascular supply, either congestion, or, as late researches on the pathology of convulsions suggest, anæmia, *i.e.*, deficient or interrupted vascular supply; (c) possibly also an œdematous condition of the nerve centres might cause the symptoms; (d) molecular physical or chemical changes, which we may certainly assume in the toxic forms (mercurial tremors). The functional are especially the curable forms of the disease.

2d. In more inveterate, especially senile cases, paralysis agitans appears to depend on a discoverable lesion; namely, an atrophic condition of the spinal cord, pons varolii, crura, or medulla oblongata (atrophic or organic paralysis agitans). This atrophy has been found in several careful dissections, and it certainly coincides with, and would explain the chief features of the disease,—namely, its obstinacy or incurability, without immediate danger to life; the progressive course; the impaired strength and muscular debility (paralysis); the occurrence in old age, after violent exertion and emotion, under conditions of premature senility, &c. In addition to simple atrophy, with serous accumulations, autopsies have revealed in different parts of the spinal cord, medulla oblongata and pons, an indurated condition (sclerosis), with patches of grey or gelatinous degeneration, due to the new formation of connective tissue, which compresses, and atrophies the proper nerve structures.† Since a similar condition, involving extensively the posterior columns of the cord, is the chief lesion found in Progressive Locomotor Ataxia (Tabes dorsalis), some relation is established between it and paralysis agitans.‡ It is curious that Parkinson (from the report of a case not seen by himself) drew attention to the induration and enlargement of the upper part of the medulla spinalis, oblongata, and pons, as the probable morbid condition in paralysis agitans, and supposed it might be due to simple inflammation, or rheumatic, or scrofulous affection of the nervous substance or membranes. The sclerotic atrophy does not seem to be of inflammatory origin, although, according to Rokitansky, it is preceded by congestion. In the early stages, there may be softening instead of induration. Rheumatic and other morbid diatheses may probably dispose to it. Degeneration of the blood-vessels may possibly be connected with it.§ The pathogenesis of atrophy of the nerve centres, however, has not yet

† Bamberger, Skoda, Oppolzer, Lebert, &c.
‡ Also with tetanus, probably chorea, and with progressive paralysis of the insane. See Rokitansky, Ueber Bindegewebs-Wucherung im Nervensysteme. Wien, 1857. Cruveilhier, &c.
§ In Skoda's case the nerve elements were destroyed in some parts of the brain, the pons and medulla, by embryonal connective tissue; the vessels were obliterated; the muscles were in a state of fatty degeneration; the neurilemma of the nerves of the upper extremity was thickened. The thickened neurilemma has been observed in other cases.
been fully investigated; and, although highly probable, it cannot yet be positively affirmed, that paralysis agitans depends upon atrophy, simple or sclerotic, of certain parts of the cerebro-spinal axis. In regard to symptomatic paralysis agitans, the tremors are ascribed to the atrophy of the nerve substance surrounding the tumour or other principal lesion.

But whether the disease be functional or organic (atrophic) in its nature, it clearly affects the motor centres only, exempting the sensory and the intellectual, and, further, the morbid state of the nerve centres implies not only diminished power, but some condition of spontaneous irritation, giving rise to the spasmodic jactitations even during rest. Probably the degenerative molecular changes in the nerve structures may occasion a disturbed equilibrium and consequent irregular discharge of nerve stimulus. The morbid process is presumed to begin usually in the cervical portion of the spinal cord, since the arms are apt to be first affected, and the disease presents the bilateral type. But the occurrence of the unilateral form, as well as the fact that the limbs are much earlier affected than the trunk, shows that the possibility of the cerebral centres of motion being sometimes attacked should not be overlooked. The disturbed equilibrium probably ensues, when the parts in the vicinity of the pons varolii are involved, and the extension to the medulla oblongata is indicated by the impaired speech, deglutition, &c., which supervene in the advanced stages of the disease.

Should future researches confirm the results above indicated, there would then exist a secure basis of morbid anatomy for the distinctions which authors have indicated clinically, of Idiopathic Paralysis Agitans into functional and organic; the latter with, the former without atrophy of the nerve centres: the latter mostly incurable, the former admitting of cure.

The Prognosis is unfavourable, but depends upon the age of the patient, and the particular form of the disease. When fully established, idiopathic paralysis agitans is an obstinate, and in the aged, with rare exceptions, an incurable disease. But, unless mixed with signs of senile decay, paralysis agitans does not endanger life, and its course is often indefinitely protracted. As a rule, it is obstinate in proportion to the age of the subject, and is fatal only in the old. The distinction of curable and incurable, functional and organic (atrophic), has been already sufficiently indicated. It needs only be added that mere violence of the jactitations is no evidence of incurability; slight tremors are frequently the most obstinate; it is the persistence of

* "Morbus valde pertinax," Juncker. Comparing it with apoplexy and motor palsy, &c., he says it is inferior to them in danger to life, but equals them in its resistance to treatment.

† Dr. Russell Reynolds, in a letter, June 1, 1865, says: "From what I have seen of a large number of cases I am led to believe that there is a most important difference between those cases in which there is trembling only, and those in which there is clonic alternate spasm. In the latter the prognosis is very much more favourable than in the former." The age of the patient and stage of the disease being, of course, taken into account.
tremors during absence of voluntary effort, and especially during sleep, the occurrence of disturbed equilibrium, and symptoms of senile decay which are of serious import. Disturbed equilibrium is apparently incurable in itself, as well as of bad augury for the disease generally. The supervention of convulsions, apoplexy, motor or sensory paralysis, indicates more immediate danger to life.

In the Registrar-General's Reports for England and Wales, from 1855 to 1863 inclusive, 205 deaths from paralysis agitans are recorded, 129 being males, and 76 females; on an average about 14 males and 8 females annually. Of these 205, 189 were above 55 years of age; nearly half, viz. 91, occurring at 65 years; only 16 below 45 years, one death taking place at 20 years. It may be doubted, however, whether the cases fatal below the age of 45 were true idiopathic paralysis agitans; more probably they were examples of spinal or cerebral disease accompanied by tremors, i.e. by symptomatic paralysis agitans.

Of the Modes of Termination, the principal in the senile disease is by general decay of the system. Sometimes life is cut short by the intercurrence of the usual diseases of old age. Trousseau states that in three cases which he traced to the end, the patients all died of pneumonia. The non-senile forms of Paralysis Agitans are not known to have any special mode of termination.

TREATMENT.—The modes of treatment and remedies employed are numerous, but few have been attended with success. Allowance must be made for the form of the disease; the senile being mostly incurable, the non-senile obstinate, but susceptible of relief or cure. The physician must keep in mind the propriety of abstaining from remedies in inveterate cases, after a fair trial has been given to them; a fruitless perseverance would only injure the general health and excite false hopes. At the same time, general hygienic measures are always beneficial, and, by their means alone, the symptoms may be alleviated, and life prolonged to advanced age.

The methods of treatment are,—

1. Antiphlogistic.—This used to be commonly practised on the supposition of the congestive or inflammatory nature of the affection of the spinal cord. In some cases in an early stage, it seems to have done good; purgatives, indeed, in judicious moderation, are useful in all cases, and they cure the forms depending on disordered prime (Tremor a saburrâ). The means employed were: Venesection general or local, purgatives, diaphoretics, mercury; blisters, setons, cauteries actual and potential, moxas, &c., to the spine; frictions, stimulant embroctions, hot baths, &c. In the majority of cases, however, this practice did no good or did positive harm. The treatment now preferred, especially in chronic cases, is

2. Tonic, general and nervine. Hygienic regimen, nutritious but not stimulating diet; little wine; rest or moderate exercise, light gymnastics. Excessive exertion is injurious, and many cases of simple paralysis
agitans are aggravated by the patients when poor being compelled to work, or when rich, endeavouring by forced exercise to overcome the debility in which they suppose their disease consists. Subcarbonate of iron has been a noted remedy in consequence of Elliotson having cured cases by it in persons under 50; it failed in older patients. Quinine, zinc, arsenic, nitrate of silver, chloride of gold; Strychnine, which has apparently cured some, and failed in other cases; Ergot, said to have been beneficial; iodide and bromide of potassium, balsams, oil of turpentine, sarsaparilla, quassia, colchicum, &c. Iceland moss; Mineral-waters, sulphurous or chalybeate; sea or mountain air, the milk cure, &c.

3. Narcotics and Calmants.—Opium, belladonna, henbane (5ss. of Tinct. thrice daily, used successfully in functional paralysis agitans by Dr. Handfield Jones); stramonium; chloroform stops the tremors at the time, but does not appear permanently beneficial; ether, musk, camphor; veratrin, externally or internally, reported successful in a case by Volz; valerian and valerianate of zinc; Calabar bean, tried without success by Dr. J. W. Ogle.

4. Baths have been much resorted to, sometimes with success, often without effect. Warm sulphur baths, especially of liver of sulphur, have been specially recommended. Simple warm baths with cold douches (Romberg). Vapour baths, Russian baths, and baths of gelatine, fir-tops, mud, even animal baths, have been used in Germany. The water cure, cold affusions; sea-bathing, which rendered one case stationary (Lebert); brine baths, ice baths, first tepid, gradually made colder. It should be remembered that some of these, especially the cold-water cure, are not free from danger, and require proper caution in old persons; sometimes they aggravate the disease.

5. Electricity and Galvanism.—Partially successful in previous experience, electricity was found to produce no improvement in four cases observed by Gull. The interrupted galvanic current appears also to have been of little service; but the continuous current recommended by Remak proved successful in his hands with a patient, aged 60, and others were benefited by it. In a man, aged 57, the disease, well marked though recent, was cured in this manner by Dr. Russell Reynolds. After five applications of Pulvermacher's chain of 120 links, daily, for one hour, the spontaneous jactitations completely ceased; the same treatment, continued every second day, completed the cure in about a month. In other instances, this means has not produced such favourable results, but it deserves a persevering trial in all cases.

On the whole, good hygienic rules, attention to any special indications, gouty, rheumatic, &c.; regulation of the primæ viæ; the administration separately or combined of general and nervine tonics, and calmants; and the judicious use of the continuous galvanic current are the measures chiefly to be recommended. Depletion and counter-irritation are seldom required, and would in most cases be highly injurious. Time must in all cases be allowed, for the affection
PARALYSIS AGITANS.

is obstinate. In the confirmed senile forms, we may be satisfied with arresting or mitigating, but must not expect to cure the disease.

A SYSTEM OF MEDICINE.

METALLIC TREMOR. TREMBLEMENT METALLIQUE.

By WILLIAM RUTHERFORD SANDERS, M.D. F.R.C.P.

SYNONYMS.—Tremor Metallurgorum; Paralysis Agitans Metallica; Rheumatismus Metallicus (Schönlein); Metallic Shaking Palsy; The Trembles.

1st. Mercurial Palsy or Tremor; Mercurial Shaking Palsy; Mercurial Trade Disease; Tremor ab Hydrargyro; Paralysis Agitans Mercurialis; Tremblement Mercuriel; Tremblement des Doreurs; Mercurial-Zittern.

2d. Lead Tremor or Shaking Palsy; Tremor Saturninus; Paralysis Agitans Saturnina; Saturnines Zittern.

DEFINITION.—Metallic Tremor is a species of paralysis agitans, caused by the slow poisonous action of certain metals, particularly mercury and lead. It consists of spasmodic tremors with diminished muscular power, occurring in various parts of the body.

1. The Mercurial Tremor, or Shaking Palsy, being the form best known and most important, will be first described.

CAUSES.—Exciting.—The chief source of this disease is the inhalation of mercury in a state of vapour, this metal being volatile at nearly ordinary temperatures (68° to 70° Fahr.). By some authors this has been regarded as the only mode of origin; but it is certain that the introduction of mercury by the skin either in consequence of manipulating the metal, or of prolonged friction with mercurial ointment, has sometimes brought on the peculiar tremors; and the same effect has also resulted, in a few instances, by absorption, from the intestinal canal, of mercurial preparations administered medicinally. The principal sufferers from the disease are accordingly:—1st. The workmen employed in the quicksilver mines, especially when fire is used in the reduction of the ores. 2d. Water-gilders (who plate with gold dissolved in mercury), looking-glass silverers, barometer makers, workmen in chemical manufactories, where mercurial preparations are made, button and toy-gilders, furriers, and others whose business
exposes them to contact with mercury.* 3d. Persons using mercury medicinally. In former times, the latralipte, an inferior class of surgeons, who practised as mercurial anointers or rubbers, without protecting their hands, were frequently subject to tremors which sometimes proved incurable. A similar instance is recorded recently. Dixon, the anatomy porter of the Irish College of Surgeons, "who at one time rubbed in immense quantities of mercury for the cure of venereal among the Mohawks, or swells of the day," was subject for thirty years to mercurial stammering (psellismus mercurialis).† Syphilitic patients, after long courses of mercurial treatment, especially by friction, often suffered severely from the trembles.‡ On the other hand, the internal use of mercurial medicines alone very rarely gives rise to the tremors; nevertheless undoubted examples of this kind have been observed even in recent times, both in venereal and in other cases.§ In the present day, there is little risk of tremors originating from excess in either the external or internal medicinal use of the mineral, but the possibility must not be overlooked. 4th. Persons are sometimes accidentally exposed. In 1810, the Triumph, man-of-war, took on board a cargo of mercury, saved from a wreck. In consequence of the bladders bursting, in which it was held, the mercury spread through the ship, and in the space of three weeks, "two hundred men were afflicted with ptyalism, ulceration of the mouth, partial paralysis in many instances, and bowel complaints."|| In 1803, a fire broke out in the quicksilver mine at Idria, near Trieste, and above nine hundred persons in the neighbourhood were attacked with nervous tremblings.¶ Medico-legal questions have also arisen as to the alleged deleterious effects of emanations from workshops where mercury was used.**

In a few instances a single strong exposure has been known to cause the tremors; †† but usually a prolonged and habitual contact, for months or years, is required, under conditions which favour the development of the disease.

Predisposing Causes.—The circumstances which dispose to the disease or aggravate it, are:—1st. Bad ventilation; 2d. Cold and damp weather; hence the tremors are worse in winter, in consequence of the low temperature and close confinement; 3d. Defective cleanliness; 4th. Intemperance; 5th. Violent emotions: a fit of passion has some-

times originated an attack of tremors suddenly; 6th. Idiosyncrasies must be taken into account. Certain constitutions are more susceptible than others to the mercurial poison. The same exposure which in some individuals affects the mouth, producing salivation and ulcerations of the gums, without tremors, will, in others, cause tremors without salivation. 7th. The mode of application has considerable influence. As a rule, inhalation of mercurial vapour is followed by tremors; injection or internal medicinal use, by salivation.

DESCRIPTION.—Previously noticed by several writers, and especially by De Haen,* the tremulous mercurial disease has been most fully described by Mérat,† as observed among the water-gilders of Paris. Less complete accounts have been given by various authors of the disease among workmen in other countries, and as it affects the quicksilver miners at Almaden and Idria.‡

SYMPTOMS.—1st Stage. Simple Tremors.—The commencement is sometimes sudden, but most frequently the disease comes on gradually. The upper extremities are nearly always first affected. The patient finds his hands and arms getting weak, unsteady, and less under control; they vacillate and tremble whenever they are used. He can do coarse work, but nothing requiring precision. The attempt to seize or hold anything increases the trembling. At the same time, numbness or formation is sometimes felt in the hands or feet, and occasionally pains in the joints, particularly the thumbs, elbows, knees, or feet. These simple tremors are very common among quicksilver miners and water-gilders. They are not so severe as to prevent work altogether, and by judicious means they may be kept from increasing.

2d Stage. Convulsive Tremors.—If the patient continues or increases the exposure, or becomes more susceptible to it, the trembling augments in intensity till it becomes convulsive or spasmodic in character. Muscular subsultus occasions vibration and jerking of the hands and arms. The tremor is easily excited either by exertion or emotion, and once begun cannot be stopped for some time. The voluntary acts also become spasmodic as well as tremulous, and are accomplished by interrupted violent starts, like the movements in chorea. In bending the arm, for example, the flexion cannot be done by a single continuous contraction, but takes place by two or three jerks. The tremulous hand cannot be directed with precision, but is projected beyond or beside or away from the object; it soon becomes unfitted for work, and

* De Haen, Ratio Medendi, Pt. iii. c. 28, 1761.
‡ Jussieu, Mém. de l'Acad. Roy. des Sciences, de l'Année 1719, p. 357, &c.
can scarcely convey food or liquids to the mouth. As Dr. Pope tells of a miner at Friuli, "he could not with both his hands carry a glass half full of wine to his mouth without spilling it, though he loved it too well to throw it away." The convulsive nature of the movements depends greatly on the predominance of the flexors over the extensors; so that when a patient has seized an object, he often cannot let go his grasp. At this period, the patient is usually obliged to discontinue work, and after an interval of rest, steadiness may still be completely restored. But if he persist, or resume his employment too soon, the tremors become greatly aggravated, and extend by degrees over the whole body. The legs begin to shake, especially at the knees, and in walking they tremble and dance as if hung upon wires. The lips, tongue, and jaws are in tremulous vibration, and speech is hurried, staccato, and stammering, becoming at last unintelligible (psellismus mercurialis). The head oscillates, shaking, or nodding; and sometimes the features are distorted by spasmodic grimaces; the eyeballs alone are unaffected in their movements. Mastication is impeded. Finally, the tremulous subsultus appears in the muscles of the trunk, and the respiratory movements are convulsive and attended with dyspnœa. Tonic spasms also occur in the affected parts, and are frequently attended by pains, to which the Spanish miners of Almaden give the name of "calambres," i.e. cramps. These pains are sharp and lancinating, and sometimes of intolerable intensity; they are not always in proportion to the muscular contraction.†

When the tremors attain their greatest intensity, they amount to a kind of convulsion, and the patient presents a most pitiable aspect. In constant tremulous commotion, tottering, trembling, shaking, and stuttering, he is powerless to execute any combined movement; he cannot walk, or speak, or chew; he dares not touch any object for fear of breaking it or letting it fall; on raising his agitated hand, with food, to his mouth, he misses his aim and inflicts involuntary blows on his face. He must be fed and clothed like a child.‡ Some unfortunates, deprived of assistance, have been known to creep on all fours, and seize their food with the lips, like the lower animals. Unless in the very worst cases, however, whenever the body is supported, sitting or reclining, the tremors gradually subside, and cease soon altogether, and they do not return until excited in consequence of some voluntary movement or mental emotion. During sleep, they remain in entire abeyance. The patient is thus allowed time for

* Phil. Trans. i. p. 21, 1665.
‡ De Haen's description is graphic. Case 2: "Deaurator, 25 annorum, horrendo artaum omnium, maxime superiorum... vexatus... ita ut nihil laboris ultra percire, ut nec comedere, bibere, solus, nec loquens amplius intelligi potuerit. Nutrientus, vestiendus et infantis instar, alvum urinamque positurus, adjuvandus erat; dolorum ceterum immamus." It is satisfactory to add, "Virtute electēa trium septimanarum spatio adhibita, perfectissimē convuluit, ita ut ipsi, sive in motu, sive in loquelâ, ne vel minimum quidem desit."—l. c.
repose and recovery. But in the most advanced cases, the subsultus takes place even when the body is reposing, so that the involuntary shaking of the head on the pillow has prevented sleep.* In the tremulous parts, the muscular strength is diminished (paresis), but there is no interruption to the conduction of the stimulus of volition (paralysis). The sensibility is not impaired.

Concomitant Symptoms.—The condition of the other functions, accompanying the disorders of the nervous system just described, indicates the presence of the mercurial cachexia. At the beginning this is slight and unimportant. The skin exhibits a sallow, brown, or earthy tint; it is dry and sometimes rather warm; the expression is sometimes animated, at other times languid; there is little or no emaciation, which, indeed, does not appear till the disease is of long standing. The digestive functions are unimpaired; there is no colic, the abdomen is soft and of ordinary volume, and the urinary and alvine excretions are natural. But as the tremors become more severe, the appetite diminishes, and it ultimately ceases altogether; the tongue becomes white and pasty, but without bad taste, and gas accumulates in the intestines. The respiratory organs are natural, till dyspnoea and asthma arise, from the respiratory nerves being involved in the tremors. The pulse is usually at first strong and slow, as in metallic colic, but it may afterwards become small and weak; sometimes it is accelerated.

But sooner or later signs of general mercurialism usually make their appearance, especially salivation, loose teeth, inflamed and ulcerated gums, aphthæ, fetid breath and sweat, swelling of the parotids, and a pustular eruption over the body. These symptoms occur early, and are particularly obstinate in workmen who take their food in the workshops or mines, and who are not careful to use ablutions, and change their clothes and shoes. Attacks of excited circulation (erythmus) are frequent in the early stages; and in the later, anæmia, emaciation, and great debility. If we except the cachectic symptoms just described, complications are rare in the course of mercurial tremors. The colic, which is sometimes observed, depends upon lead which is mixed with the mercury, or has been used along with it.

3d Stage. Mercurial Tremors, with Affection of the Brain.—The tremors are not of themselves dangerous to life, but in the advanced stage they are often accompanied by serious cerebral disorders, as headache, loss of memory, loss of consciousness, sleeplessness, delirium, epilepsy. These symptoms would soon end fatally were it not that generally their gravity compels the sufferer to desist from his employment; and by this fortunate interruption, recovery usually takes place even from this dangerous condition. Indeed, the disease when subjected to treatment is rarely fatal.† Some inveterate cases prove incurable, or are succeeded by motor paralysis, but it is only in those instances where the noxious exposure is obstinately persisted in, not-

* De Haen, loc. cit. case 7.
withstanding repeated attacks of increasing severity, that death finally takes place, accompanied by symptoms of profound mercurial cachexia, and especially extreme marasmus and exhaustion.

But although mercurial tremor by itself is not directly fatal, and is a curable disease when submitted to proper treatment, yet, under the circumstances in which workmen were placed till within a recent date, the effects of the mercurial poison, taken as a whole, were most disastrous, and the mortality in certain employments was excessive. In Paris, in 1821, it is stated that the looking-glass manufacturers could not remain at the trade above eight or twelve years. When necessity compelled them to persevere too long, their faces became pale, with an expression of intoxication, their intelligence and memory gradually failed, they fell into a kind of idiocy, and after lingering in this state for some years, they died of consumption, or were struck with apoplexy.*

In 1847, Dr. Sanderet reports that the trade of water-gilding at Besançon, where it was extensively carried on, was most injurious to health,† the mortality among the workmen being enormous, and due chiefly to phthisis. Fortunately these trades, conducted under better hygienic conditions, or by means of new processes, are either entirely innocuous or are much less injurious at the present day.

The condition of the quicksilver mines was, in ancient times, most dangerous.§ At a comparatively recent date, when Jussieu visited Almaden, in 1719, he found that the free miners, who adopted proper precautions, preserved their health and lived like other men, but the convicts and slaves who took no care, suffered severely, and fell victims to disease. In 1848-9, there were no slaves nor convicts in those mines; but it was observed that the native miners, who knew the risks and avoided them, were little affected, while the poor labourers from a distance, careless and dissipated, experienced the most disastrous effects. The average number of workmen was 3,911; of these forty-eight were “calambristes” (in the 2d stage of mercurial tremors), half of which number died within the year, and the other half remained unfit for work in the mines. Besides this, there were two deaths from accidents, three mutilations, and thirty-nine injuries more or less serious. And although many workmen do not fall victims to the mercurial poison, none of them entirely escape its action.§

At Idria, although the hygienic conditions of the place are in other respects highly favourable, it is stated that the whole population is subjected to the influence of mercury, not the workmen at the mines only. The annual mortality is 120 out of 4,500 inhabitants. The workmen ex-

§ Tardieu, loc. cit. and Roussel. In the enclosure called Brutrones, where the furnaces are situated, the animals which are allowed to graze there are liable to Mercurial Tremors. Ed. Month. Med. Jour. Retrospect for 1848, p. 255.
posed directly to the action of the metal suffer severely. In 1856, 122 out of 516 were seriously affected.* Information is wanting in regard to the quicksilver miners in California and Australia.

Course and Prognosis.—Mercurial Tremor is essentially a chronic and protracted disease. It runs a uniform course. Once begun, if the exposure is persevered in, the symptoms gradually get worse; the tremors become more intense, are accompanied by spasms clonic and tonic, and spread over the whole body. But if the patient be removed from the exciting cause, exposed to fresh air, and placed under suitable treatment, amelioration soon begins, and, after a few weeks or months, perfect steadiness may be restored. The prognosis, therefore, is generally favourable, provided the patient can avoid the contact with mercury. The prospect of cure, and the time required for it, will depend on the severity of the symptoms, and especially on their duration previous to treatment, on the age of the patient, the presence of serious cerebral symptoms, and the degree of mercurial cachexia which may accompany the tremors. The affection is most frequent probably in middle life (thirty to forty); it is more severe in old people. If taken at an early stage, twenty days may effect a cure, but in a confirmed case, usually from two to seven months, sometimes a year or more, are required. When the tremors are spasmodic and generalised, the cure is tedious and imperfect, some tremor of the hands nearly always remaining permanently. The upper extremities, which are the parts earliest and most severely affected, resist cure the longest. It is seldom that the tremors are persistent and irremediable, and, as already stated, fatal results only ensue in consequence of general cachexia or phthisis or apoplexy, the effects of an unhealthy constitution, or of unpardonable neglect, or of obstinate persistence in exposure to the poison.

After a first seizure relapses are frequent, and usually of increasing severity. If the patient, in spite of due care, is still subject to attacks, he ought to change his employment. Some constitutions, peculiarly sensitive to the poison, are unfit for any trade requiring the use of mercury.

Diagnosis.—The symptoms and the cause distinguish Mercurial Tremor readily from other diseases. It could only be confounded, 1st, with chorea, or St. Vitus’ dance, which it resembles in the jerking nature of the movements; but it differs by the presence of tremors; 2d, with idiopathic paralysis agitans, with which it is identical as regards the character of the irregular movements (viz. tremors and jerking), but it is distinguished from it by the exciting cause (mercury), and by the concomitant symptoms of mercurial poisoning. In addition, the speech (tongue and jaws) are much sooner, more invariably, and more characteristically affected in the mercurial disease than in idiopathic shaking palsy. The loss of memory and consciousness,

and other cerebral symptoms also, are peculiar to the mercurial disease. On the other hand, the irresistible tendency to walk or run forwards, which marks the paralysis agitans festinans, is not met with in the Mercurial Tremors; the only disturbance of equilibrium in the latter is that which results from debility, tremors, and spasmodic jactitation.* 3d. It is not likely, with ordinary care, to be mistaken for delirium tremens, or alcoholism.

PATHOLOGY AND MORBID ANATOMY.—The disease being rarely fatal, the information in regard to the morbid anatomy is scanty. In a recent case,† Dr. Alfred Taylor found the brain and spinal cord, the muscles, lungs, heart, liver, and kidneys, in appearance quite healthy. On chemical examination of the brain, liver, and kidney, minute globules of metallic mercury were obtained, in largest proportion from the kidney. The spinal cord and medulla oblongata are doubtless the seat of the principal morbid action, just as in idiopathic paralysis agitans. The molecules of mercury entering probably into combination with the nervous substance, seem both to irritate, and partially to paralyse the nervous centres of motion, while they leave the apparatus of sensation intact.‡ The opinion which some authors entertain, that the morbid lesion has its seat in the muscles and not in the nerve centres, is insufficient to account for the spasmodic and variable nature of the phenomena, and is inconsistent with the cerebral symptoms which ultimately become developed.

The treatment is twofold, preventive and curative.

Prevention is accomplished, 1st, by limiting the exposure to a short period at considerable intervals, or by adopting various contrivances which remove the mercury from contact with the operator. In the time of Pliny§ the workmen protected their faces with masks of loose bladder skin, sufficiently transparent to admit of being seen through. Masks of glass were afterwards substituted. Sponges over the mouth, and various kinds of respirators, have also been proposed. But the chief improvement has taken place in recent times by the better construction and ventilation of the workshops, and by the introduction of flues and chimneys, which carry off the mercurial vapours by a powerful draught out of the apartment, while the workman is further protected by a glass sash interposed between his face and the stove where the mercurial vapours are disengaged. To D'Arcet's ‖ draught chimney for this purpose the French Academy of Sciences, in 1816,

‡ Jussieu's idea of the pathalogy is curious. The tremors, he says, are "les tristes effets du séjour du sang dans les vaisseaux du cerveau, dévenus variqueux par le poids de quelques particules mercurielles, qui y ont séjourné." Loc. cit. p. 360.
§ Hist. Nat. xxxiii. 40.
awarded the prize founded by M. Ravrio, who had made his fortune as a manufacturer of gilt bronzes, and was anxious to obtain some means for protecting workmen from the risks of the employment. Merat bears testimony to the efficacy of D’Areet’s chimney in warding off the tremors, to some extent. Similar flues and stoves have been used in this country;* but none of these inventions have proved successful in entirely preventing the disease. 2d. On the part of the workmen, regular habits, personal cleanliness, change of clothes, frequent ablutions, and the practice of never eating in the mine or workshop, or with unwashed hands, are essential. Intemperance invariably predisposes to or aggravates the disease. Melsens observed that workmen who used much salt with their food are less liable to suffer from Mercurial Tremors, and he also recommended the iodide of potassium as a powerful preservative. Of late years in this country Mercurial Tremor has greatly diminished in frequency, and under proper hygienic rules would probably cease altogether, at least in its more aggravated forms. Water-gilding, the most dangerous kind of mercurial trade, has been now almost altogether superseded by electro-plating, which is completely innocuous. Looking-glass silvering, when conducted in large, well-ventilated apartments, with means for preventing the diffusion of the metallic dust, is also quite safe, if the workmen are employed only at intervals, and are careful and temperate. But when these conditions are not attended to, and especially if the men are kept too continuously at work, slight tremors soon make their appearance, and severe cases occasionally happen.† According to Dr. Whitley’s report,‡ the number of persons affected in England and Wales appears to be small, and the cases, for the most part, slight. The same statement may be applied to Scotland and Ireland. The condition of the quicksilver mines is probably still one of considerable danger to health and life. But full and accurate information is wanting in regard to the amount of sickness and mortality among the miners, and the means used for their protection.

The Curative treatment consists, first, in complete removal of the patient from his noxious employment; next, in change of dress, ablation, exposure to a free atmosphere of moderate temperature, and the administration of a nutritious tonic diet. The objects of treatment then are, 1st, to eliminate the mercury from the system by the secreting organs. Sudorifics§ have been much used for this purpose: acetate of ammonia, Dover’s powder, guaiac, sarsaparilla, sassafras, &c.

† See recent cases, Scott Orr in Glasg. Med. Jour. i. 37, May 1866, and Mapother, loc. cit. Also Taylor, loc. cit.
‡ Sixth Report of Med. Officer of Privy Council for 1863, p. 22 ; and 1864, p. 358.
§ Jussieu remarks (1719) that at the mines of Almaden the medical treatment differed from the usual practice then in vogue of purging and bleeding, and consisted simply in exposing the patients to the free air, and administering absorbents, as harts horn, ivory, or crab’s-eyes; and what is singular (he adds) the treatment succeeds mostly always in temperate subjects and those who abstain from wine, while those who indulge perish without resource. Loc. cit.
Sulphur has been regarded by some as specific; warm and vapour baths, or sulphurous baths, &c. are always employed. Neufchâtel had a reputation for the successful treatment of water-gilders’ palsy, chiefly by means of vapour baths. Diuretics have become favourite remedies, and especially the iodide of potassium, since Melsens brought evidence to show that this salt has the power of redissolving the mercury contained in the tissues and eliminating it by the urine, in which its presence may be detected chemically. The caution must be observed not to give the iodide so largely as to disengage an excess of mercury at once within the body. Various other diuretics, common salt, bitartrate of potash, &c. may be employed. Purgatives are also useful. 2d. Another indication is to soothe and strengthen the nervous system, by means of antispasmodics, narcotics, tonics, and stimulants. Steel and quinine, singly or in combination, are especially serviceable. Opium is useful. Nitrate of silver has also been recommended. Stimulants, particularly alcohol, wine, &c. exert a powerful immediate effect in arresting the tremors; hence workmen are apt to resort to them to steady their hands; but when the immediate effect is over, they aggravate the tremors. The most beneficial stimulants are electricity and galvanism, which have afforded very satisfactory results. De Haen’s cases were cured, some of them rapidly, with electricity as the only remedy applied.

2. Lead Tremors; Tremor Saturninus; Paralysis Agitans Saturnina.

Merat denied that any other metal than mercury could give rise to tremors, and, with few exceptions, other writers appear to be of the same opinion. In regard to artisans using lead, this view is probably correct; but the case is different with miners exposed to the vapours of the metal. Brockmann, in particular, from his experience in the Harz Mountains, has described a species of lead tremors, which affects the miners there, and which is almost identical with the mercurial shaking palsy, consisting, like it, of oscillating spasmodic contractions of the muscles, and consequent tremulous motion in various parts of the body. His account includes two forms, the local (partialis) and the general (universalis), both the result of an affection of the nervous centres by lead.

* Sanderet, Ann. d’Hygiène, 1847.
METALLIC TREMOR.

215

Symptoms. 1st. Tremor Saturninus partialis.—As a rule, the upper extremities are alone affected. The arms and hands are in continual vibration, more or less, greatest when any powerful effort is made or during emotion. With this there is often associated a peculiar nervous tremor of the lips (musc. orbic. oris) and angle of the mouth (levator anguli oris), like that observed when a shy sensitive person opens his lips. The local tremor usually follows violent and persistent attacks of lead colic, especially in highly nervous subjects, or in those exhausted by previous disease. It disappears mostly in a few days, but is apt to return when the exciting causes are renewed. Under very unfavourable circumstances, however, it may increase and extend into the general form of the affection.

2d. Tremor Saturninus universalis.—In this the tremors are not confined to the arms, but appear in the legs and muscles of the head and trunk. The patient presents a peculiar and pitiful aspect. When at rest, his back is bent like an old man’s, his head is bowed, and the chin falls upon the breast; in walking the legs are rotated tremulously as in paralysis agitans. In advanced cases the jaws, and indeed all the muscles of the head and body, are the seat of the uncontrollable tremors which characterize the disease.

Causes.—The general tremor never results except from deeply-rooted lead-poisoning. It is preceded by repeated outbreaks of the severer forms of lead disease, and progresses hand in hand with the lead cachexia. All the causes of the cachexia predispose to it, and the tendency is increased by an excitable nervous constitution, together with lax fibre, and weak muscular system. Age has no appreciable influence. The saturation of the system with lead is the only exciting cause of the disease.

The course of the general disease is chronic and very protracted. Months or even years elapse before permanent improvement takes place. Often a radical cure is impossible. Frequently, also, the tremor becomes associated with some form of anaesthesia, or ends in complete paralysis.

The Prognosis is consequently almost always unfavourable. Only when the disease is partial, and follows a violent colic, or an acute attack of convulsions, can a speedy favourable issue be anticipated. Under all other circumstances, lead tremor is a most serious affection, and is apt to be the precursor of more sudden and dangerous disorders, such as paralysis or cerebral disease.

Pathology and Morbid Anatomy.—No specific lesion has yet been pointed out in the brain or spinal cord. The affected muscles have been found altered, but this is of subordinate importance. The pathology is, doubtless, analogous to that of mercurial tremor, and idiopathic paralysis agitans.
The Diagnosis is sufficiently determined by the symptoms of the lead cachexia, which accompany the tremors, and by the absence of any source of mercurial poisoning.

The Treatment must be directed to neutralise the lead poison, and to strengthen the nervous centres, which are the chief seat of the disease. The energetic employment of sulphur baths, cold water douches to the spine, and the internal use of nervine tonics, nux vomica or strychnia, valerian, quinine, &c. are the appropriate means. Sudorifics, sarsaparilla, &c. have also been used, and Melsens recommends the iodide of potassium on the same grounds as in the case of mercury. Brockmann states that he never concludes the treatment without the persevering use of baths of aromatic herbs, and the cold plunge bath, as well as the internal administration of chalybeates. In obstinate cases electricity and galvanism must be resorted to, but frequently without much success. The most essential part of the treatment consists in the removal of the patient from his unhealthy employment, and placing him in free pure air, with a nutritious animal diet, and a moderate allowance of good wine and beer.

In poisoning with arsenic, zinc, and bismuth, tremors frequently occur, but they form only part of a general group of symptoms, and do not constitute a disease requiring particular description, as in the case of mercury and lead.
CONVULSIONS.

By J. Hughilings Jackson, M.D.

It cannot be kept too much in mind that a Convulsion is a symptom, not a disease. Yet it is usually the most striking individual symptom of the series in which it occurs; it is, indeed, sometimes the only one about which we have much definite knowledge. In other words, although we always believe a Convulsion to be symptomatic, we know very little, in many cases, about the real condition of the system in which it forms one of the symptoms; and this, too, even after post-mortem examination. Just as a single word conveys no proposition, so the phenomenon Convulsion can have no complete meaning by itself.

Convulsions occur in association with obvious organic changes in the nervous system of the most varied kinds, such as cerebral haemorrhage, intracranial tumours, and softening of the brain. They follow injuries to the head, either immediately or remotely, for they are due either to the direct effects of the accident, or to the secondary effects which, in time, the principal lesion may produce. They occur in a healthy but parturient woman after severe losses of blood, and in an unsound man because his diseased kidneys do not allow the waste of the tissues to pass from the blood, and thus the body poisons itself. They come on as indirect results of cachexia, like syphilis: Some believe that Convulsions may be the results of mere passing disturbances in parts of the body remote from the brain, such as may be provoked in the nervous system by the irritation of the coming through of a tooth, or by worms in the digestive canal. Finally, there are a large number of convulsive seizures which, for want of knowledge—even of the approximative knowledge we have of such causes of fits as are given above—we are obliged, to dismiss to supposed definite groups of clinical symptoms, with the title of epilepsy or epileptiform.

This is enough to show the complexity of the subject; but when we consider further how the symptom occurs at all ages, and in many diseases, and that—if we may speak so abstractedly—there are all sorts of varieties of it in parts of the body affected by spasm, in degrees of severity and times of occurrence, we see clearly enough, that our knowledge of diseases of the nervous system from the point of Convulsions is not only small, but uncertain. I have, therefore
taken particular pains to avoid treating Convulsion as if it were a
disease.

Under the most varied circumstances of internal disease, the
paroxysms—the outward symptoms—may be quite alike. It is most
important to bear this in mind. Although from what we see of the
severity of the attacks, from observing the way in which they set in,
from noting the regions affected by spasm, and especially from a con-
sideration of the state in which the patient is left by the seizure, we
learn many things to show how much, and sometimes perhaps even
where, the nervous system is suffering; yet, from these outward
symptoms alone, we rarely, if ever, learn much that is certain of the
intimate change in nerve tissue on which they directly depend. A
diagnosis of what is actually happening to the nervous system may
often be approached by a consideration of the circumstances with
which the Convulsion occurs, but cannot be gained from the most
minute consideration of the symptom itself. The more widely we
work the less we think of the prominent symptom, and the more likely
are we to know the whole of our patient's disease.

In every symptom—sign of disorder of function—we have to ascer-
tain, when we can, (1) the organ affected, and (2) the changes in its
tissues which cause or permit (3) the disorder of function we witness or
hear described. In some cases we can thus complete our knowledge, as
in hemiplegia from plugging of the middle cerebral artery. There is
(3) paralysis, chiefly of the limbs, from (2) softening of the nerve
tissue of (1) the corpus striatum. But in many cases of Convulsions,
as in so-called idiopathic epilepsy, whilst we know (3) the disorder of
function, we know little as to (1) the organ affected, and nothing at
all of (2) the minute changes on which the disorder of function
directly depends. And even in those cases where fits occur with
obvious local damage, such as cerebral hemorrhage, or tumours of the
brain, we do not know the real position or nature of the diffused
changes in nerve tissue which immediately give rise to, or permit, the
spasm of muscles and other symptoms of the paroxysm.

It is easy to see the danger of attempting a classification of the
varieties of this symptom, and, scientifically, Convulsions should be
considered with special diseases. But there is a practical convenience
in studying this symptom distinctly, and its distinct consideration will
not be hurtful if we use it as a point around which to group, with some-
thing of method, our positive knowledge, and, if such a phrase may be
permitted, our positive ignorance also, for present action and future
research.

I repeat, a knowledge of the paroxysm, of its times of occurrence,
must never be taken as the whole of a case, even when it may be the
whole of our knowledge of it. In ancient times it was said that fits
depended on the anger of the gods. More recently such metaphysical
explanations as "irritation" have been adopted, but I suppose the
time has come when we get loose from such terms, and look at disease
as a departure from what we can learn of healthy states of tissues,
CONVULSIONS.

219

organs, and functions. Whilst we do this as well as we can, we must declare where it cannot be done, and may use terms like "irritation" not for knowledge, but to mark the place where knowledge is wanted.

Whatever else happens, it is at all events clear that in every convulsive attack nerve tissue suffers, and the practical point when we are called to a man in a fit is to learn, if not why, at least how this is suffering. Although we have few precise examinations of the state of nerve tissue in patients who have died of any sort of Convulsions, I have, for my part, no doubt that all clinical evidence points to this one general conclusion; that nerve tissue is enfeebled in Convulsions. Whether it be itself primarily in fault, or whether it suffers from want of blood, is poisoned by bad blood, or torn by cerebral haemorrhage, there can, I think, be little doubt that it is enfeebled. I merely allude to these general views, part of the teaching of my colleague Dr. Radcliffe, in order that the reader may more easily understand any apparent peculiarities of doctrine which may arise out of my adoption of them. The question, however, of the particular state or states of the nervous system in convulsive attacks will be discussed elsewhere. What I shall chiefly attempt is to show what meaning convulsive attacks have under various circumstances, e.g. as emergencies, and especially how they differ in meaning.

As the best way to perform my task, I will try to show how we should investigate and what we should attempt to accomplish when we are called to a person who is in a fit, or who has just had one. This way of handling the subject will enable me to say little on those convulsive seizures generally called epileptic or epileptiform, which are, as it were, naturalized, and which have become almost as much part of the organism as those reflex motor processes, such as sneezing or respiration, which are native to it.

It will be convenient to sacrifice some exactness to convenience, in dividing the subject into, (1) fits in infants and young children; (2) fits in children above seven years of age, and in older persons. The point of division will appear to be a very arbitrary one, but it is adopted after much consideration. I think it will prevent undue recapitulation, and I shall dwell on questions of age in different parts of the article.

CONVULSIONS IN CHILDREN.—Now, of course, convulsive attacks in young children must differ from one another just as convulsive attacks differ from one another in adults. There is nothing pathologically different in the Convulsions of adults and the Convulsions of children. I say pathologically—for there are doubtless some physiological peculiarities in the abnormal states of muscles in children, due to disease attacking the nervous system whilst being quickly developed. And these considerations are, I believe, of importance in showing the different way in which muscular groups are affected in children and adults from disease of the highest motor centres. It seems to me that the peculiarities of spasm of the hand—the well-known drawing in
of the thumb, for instance—does not attend one form of Convulsion rather than others, but that it occurs because the centre for the limbs is not so far developed in children as it is in adults. The sudden occurrence of paralysis of limited regions of muscles, as in infantile paralysis, seems to show either that the different functional centres are not knit together so thoroughly as they are in adults, or that some centre of nutrition for groups of muscles is especially selected by disease.

What I have said refers to the paroxysms, and not to conditions of the nervous system which give rise to them—to the outward signs of disorder of function, and not to the local pathological changes on which this disorder depends.

Much slighter causes will, it is believed, produce fits in children than in adults. Our spinal system, at least those parts of it of which the actions are involuntary, is more nearly perfect at birth: the brain, the motor and sensory centres for the limbs, and all the muscles we use voluntary require education. The life of the infant’s brain is vegetal rather than animal, and so is at first the life of its voluntary muscles. The actual physical development of nervous organs by growth and junction of cells and fibres, is not improbably a factor in the formation of mind out of brain. The infant can have but a rudimentary delirium, as its mind is but slightly developed. To use the language of West, “In a large proportion of cases of Convulsion in the infant, Convulsion answers to delirium in the adult.” Trousseau says that there are children who have Convulsions as easily as some have delirium, or even dreams. So much for the process of development, which gives rise to what is sometimes called the “excitability” of the child’s nervous system. Disease finds the nervous system in early life in active change, although in a healthy progressive one.

Then in children we rarely see—I never saw—convulsive attacks due to such causes as cerebral hemorrhage, except perhaps when fits occur soon after birth, and when the labour has been difficult. Moreover, the child’s tissues and excretory organs are, as a rule, more generally healthy than those of the adult, and thus, except from acute changes in the kidney, uræmic Convulsions less often occur. The child comes less in the way of blows, and is less likely to suffer from syphilis. Or, to speak generally, there are more cases in which no cause in the nervous system is discoverable, or none inferrible in the blood from disorder of other organs. Or more generally still, our ignorance of the immediate causes of children’s Convulsions is more profound than our ignorance of their causes in adults. Especially, it is believed, the cases are more frequent in which a healthy, or nearly healthy, nervous system gives way to some slight external irritation. Hence the use of the words “eclampsia” and “essential,” in speaking of the Convulsions of infancy. I believe these words are applied without good grounds. They might pass if they were used as temporary marks for a class of fits in children which occur we do not know why, and depend on supposed changes which we have never discovered. But then this
CONVULSIONS.

class would not differ from the so-called idiopathic epilepsy of adults, except in the scarcely fundamental, although very important, circumstances of age, time, and period of duration of liability. There is a great unanimity in authors as to the complete agreement of the phenomena of the paroxysms of epilepsy with those of convulsive attacks of young children, and it is at least premature to say that convulsive attacks at two periods of life differ as to their immediate causes, when we know nothing certain of the immediate causes of fits at any age. To get clear ideas we must first work at Convulsions of all sorts, from the slightest occasional spasms to the severest general seizures, and as signs of the most various pathological changes, and at all ages, as departures from health, and we may possibly then separate rationally what now can only be separated empirically.

Convulsions may occur at any age, and this remark applies to any kind of convulsive movements; but the tendency to Convulsions gradually decreases with increasing years. The following quotation from West shows this:—"In proportion as the brain increases in size, and its structure acquires perfection, and its higher functions become displayed, Convulsions grow less and less frequent, until from the 10th to the 15th year they cause less than 3 per cent., and above 15 less than 1 per cent., of the deaths from diseases of the nervous system. The first line in the accompanying table," Dr. West adds, in a footnote, "shows the proportion per cent. of deaths from diseases of the nervous system at different ages, to the deaths from all causes at the same age in the metropolis; and the second line the proportion borne by deaths from Convulsions, to deaths from diseases of the nervous system in general—

Let us suppose we are called to a child in a fit. We should consider, 1st. The paroxysm; and,

2dly. The circumstances which enable us to give the symptom a place within our general knowledge of disease.

The first is the Physiology of the muscular disturbance, the signs of loss of consciousness, &c.; the second, the Clinical History of the patient who presents the symptoms. I beg the reader to bear this distinction in mind, as it explains the order of description I follow. Much of our medical knowledge is physiology rather than pathology. The distinction betwixt the two may be arbitrary, yet it is convenient, and I hold that the two aspects of disease ought to be considered distinctly, I do not say separately, so far as they can be. The first leads us to the study of the muscular disturbance and other outward
symptoms, the second to the investigation of the nature of the internal changes on which the outward symptoms depend. The first is the study of phenomena, the second of causes, or of the circumstances which attend the phenomena.

1. THE PAROXYSM.—We must carefully note when we can the sort of Convulsion. The attacks may be slight or violent, partial or general; there may be one, few, or many; they may come on singly at distant intervals, or in batches so as to constitute the status epilepticus. The child may die of asphyxia in the first, or of exhaustion after a series; they may cease after one attack or after a series, or they may continue to adult age and beyond it.

Although there is no doubt a similar significance in the various signs of temporary muscular disorder—from abnormal motions of one limb through wider seizures up to general Convulsions—it is important to distinguish the different sorts of muscular spasms for a complete diagnosis and prognosis. Any muscular region may be convulsed. Often half of the body suffers alone, or there may be spasm of scarcely more than the hand or the foot, or of the side of the face, and in these partial fits there need be no loss of consciousness. We read of cases in which one muscle, as the biceps, is the sole seat of spasm. These partial seizures are worthy of our most careful attention, as they sometimes precede the more severe attacks which are followed by mental defect, by palsy, or by death.

The most striking variety of Convulsion is called "laryngismus stridulus," because in it the vocal cords are affected, and because a noise results from the narrowing of the glottis. There are no good scientific reasons for considering this kind of Convulsion separately, any more than there are for the separate consideration of those Convulsions which are unilateral. Rilliet and Barthez speak of laryngismus as Internal Convulsion, and most authors consider it with general Convulsions. In laryngismus, we have another series of muscles concerted in occasional spasm, and, as the group is a very important one, this internal Convulsion requires more special attention than other particular varieties. It is Convulsion affecting the muscles of respiration. It is, however, not correct to speak of it as a thoracic disease, although the phenomena are chiefly those of spasm of the diaphragm, and of the muscles of the chest and abdomen—the more obtrusive phenomenon from narrowing of the glottis not being the most important one. The fact, that so partial a Convulsion should occur, is significant, as I think, of imperfect union of different sections of the nervous system in the young. Not unfrequently, however, this form of local Convulsion runs into a more general one. Dr. West compares attacks of laryngismus to hysterical attacks, and remarks that both occur when processes of development are active. Out of thirty-seven cases of laryngismus, thirty-one, he tells us, occurred between the ages of six months and two years.

The most striking feature in this variety of Convulsion is the noise
CONVULSIONS.

made by the narrowing of the glottis, and hence the name of false or spasmodic croup. It is to be remarked, that the crowing noise is generally at first occasional, and produces little inconvenience, and very often excites no alarm in the child's friends. The next thing may be either a paroxysm, in which the costal muscles and the diaphragm are involved, and respiration much impeded, or the noise may become almost continuous in the child's ordinary respiratory movements, and the full attack may supervene in the midst of this warning.

It frequently begins insidiously, but there is great difference in this respect. The crowing noise is most frequently observed when the child awakes from sleep, and is often noticed for the first time in the night. The Convulsion may be, it is believed, at first little more than spasm of the laryngeal muscles, but at length the whole muscular system of respiration gets involved. Although we generally say spasm of the muscles of the larynx, I think it is as likely that these muscles are paralysed temporarily or continuously. Certainly paralysis of both vocal cords in adults produces a noise very like the one we hear in laryngismus. If we are called to a child on account of this noise, we should carefully look for other and obvious symptoms of muscular disorder, as clenching of the thumb and toes—carpo-pedal contractions—strabismus, and irregular movements of the facial muscles. These symptoms, which sometimes precede the severe attack, also accompany it, or, with the others, are occasionally merged in general Convulsions. They remain, too, in the intervals. They show clearly that the affinities of the disorder are primarily nervous, and only secondarily respiratory. The severe attack is paroxysmal, and while the paroxysm is on, respiration is much impeded—in the tonic stage, being indeed quite suspended, as in the first stage of complete Convulsion in adults. The first thing is the sudden fixing of the respiratory muscles, and the sign that this stage of danger is passing is a crowing or whistling noise made by air entering the now narrowed glottic aperture. In the intervals, if the attacks be not frequent, the child may be fairly alert. If they are frequent (and they may occur thirty times a day), the child may be almost comatose. Of course it is possible, although this is a rare occurrence, that the child may die in an attack, just as now and then an adult may die in an epileptic attack. As a rule, however, the child gets rid of these symptoms.

Without disregarding the value of particular convulsive seizures, due to spasm of certain definite groups of muscles which have specially important duties, we must, as regards treatment, consider the more general question of the state of the child's health or nervous system, which permits spasm of muscles anywhere. It is believed that this respiratory spasm is particularly caused by reflex irritation. It certainly occurs most, as Dr. Jenner has pointed out, in rickety children. This kind of Convulsion will, however, be mentioned no more by name, for the causes which give rise to it are essentially those which cause other varieties of concerted spasm, and the treat-
ment depends upon what we can learn of general and local states of health, and not (or very little) upon phenomena like spasm of muscles.

Any abnormal muscular action shows that there is something wrong in the nervous system, although this something may be a slight disturbance such as flatus in the intestinal canal may bring about. But when any twitching occurs on one side of the face, or in one limb, or in both limbs of one side, even if so slight a cause seem to excite it, we should fear the nervous system itself is far from sound to give way to so little. But there are often symptoms before those of disordered muscular action—although I must say that there are many cases in which a violent fit is itself the first thing wrong we can hear of—such as peevishness, want of sleep, and sleepiness. Undue irritability is in all diseases an evil sign of a feeble nervous system, and in young people it is, I think, a worse sign than failure of memory. But this—which, like the other two symptoms, shows that the child's nervous system is suffering—cannot of course be taken as evidence that the illness is one in which the symptom Convulsion will be the sole, or even the most striking event, any more than shivering or heat of skin shows that the patient is going to have a cough. In the child, as in the adult, want of sleep is associated with drowsiness. Adult patients will sometimes say what very young children are not likely to tell us, that they always feel sleepy and never sleep soundly. Children who are about to have Convulsions will sleep with their eyes partly open, and their mouths will twitch; they will start, grind their teeth, and in the day, be dull, heavy and peevish. It is, however, when the symptoms become either more decidedly local, or more generally severe, or when they occur during waking, especially if now and then a vacant look shows some loss of consciousness, however slight or short it may be, that our fear begins to point to coming severer disease with Convulsions. I may here quote as a summary what Churchill says of fits in dentition:—"I have repeatedly observed," he says, "a sort of gradation from simple irritation and restlessness to starting, surprise, wildness of look, partial or local convulsive movements, and, lastly, general Convulsions." The stupor which follows the fit is held to be the effect of the fit, and is due, possibly, to the want of properly aerated blood, or is part of what, for the want of closer knowledge, we may call with Trousseau, "cerebral surprise." Of this I shall speak again shortly.

The varieties in range and in degree of Convulsions are quite equalled by the varieties of times at which they recur. The duration of the single Convulsion is never more than two or three minutes. But the Convulsions may recur so rapidly as to make a series seem almost one continuous fit lasting for hours. Then a shorter or longer series or single fits may recur for days or for weeks.

Those convulsive attacks which are called essential or eclamptic may come on at frequent intervals for several days. In this way, however, they have no particular claim to a special name, as the epileptic fits of adults will occur in series, and be associated with
CONVULSIONS.

what is called the status epilepticus. Thus one of my epileptic patients had three hundred fits in his last illness.

This rapid succession of attacks has especially to do with the condition in which the child is left by them. If a child has one attack, no striking symptoms beyond a little weariness after such violent and sudden exertion usually follow. And if the intervals be long enough, he may after several fits seem to be in very good health. When they are frequent, however, he becomes more and more drowsy, and may become utterly exhausted, or be left profoundly comatose, and thus die either of general exhaustion of body or of exhaustion of brain. But children may get through a long succession of such attacks with life, and sometimes, it is believed, may even be well, and may keep well. They certainly frequently seem well for a time, but they certainly also sometimes become epileptic when older. This leads me to the sequelæ of Convulsions, on which, however, unless the sequelæ be nearly continuous, we have too little precise information. It is not very difficult to ascertain from the friends of a young epileptic whether he had Convulsions in infancy or not; but we have no facts on record to show what proportion keep well after having had them. I shall return to this point, for here I speak only of the more striking immediate sequelæ.

The chief sequelæ may, with great looseness, be arranged as (1) Paralysis; (2) Amaurosis; (3) Defects of Speech and Disorders of Mind; (4) Squinting. There are, of course, other defects; loss of smell, loss of hearing, and unsteadiness of gait. These, however, are less common, or have different significance, being more accidental than the other defects I have named.

Now, children are subject to two kinds of paralysis, one of which almost deserves the name of Essential, and is well enough recognised when called Infantile Palsy. The other, which will occur at any age, namely, Hemiplegia, is the form of paralysis which most frequently follows Convulsions. Convulsions may, however, attend the outset of infantile paralysis, as they will attend any sort of ill health in the child.

Hemiplegia is not a very uncommon sequela of Convulsions in a child, and it often follows certain convulsive attacks in adults. In adults it most frequently, probably always, follows those Convulsions in which one side of the body is chiefly affected by spasm. Hence it is most important, as a step towards ascertaining what will happen to the child, to see if one side of the body is alone convulsed, or suffers much more than the other. But we must be careful to bear in mind that again, as in the adult, our knowledge of the relation of Convulsion to palsy has not been reduced to rules, so that we cannot safely predict what will happen; we can only say that when fits limited, or nearly limited, to one side are very frequent, paralysis is likely to remain; but it comes on after one Convulsion, and sometimes, of course, without even one, if we accept the accounts we receive. When a child is found hemiplegic, we cannot be sure the paralysis did not
follow a fit unobserved in the night. Paralysis, I say, may remain; as doubtless betwixt the single attacks of this kind there is usually more or less palsy of the muscles convulsed, but their partial and temporary state may not be seen through the general stupor; and slight weakness may pass off when the Convulsions have ceased to occur. The child’s friends are often long in discovering loss of power in a limb, and it is not easy for us to demonstrate it when the stupor is great. We should, I repeat, always look for hemiplegia when the Convulsions are unilateral. And when it is discovered, it is not easy to say how long it will last. A child may be hemiplegic the whole of its life after one fit of Convulsion in infancy, or the palsy which is found after many, may only exist a few days. I know of no rules to decide on this question of time. When, however, rigidity sets in, we should fear that the paralysed limbs will never get well; and when the muscles have wasted, or perhaps when they, and even the bones, have ceased to grow, at the rate of the rest of the body, we see that the system has accepted the facts of the loss of their function. They have but a vegetative life, and that an imperfect one. Then, again, a hemiplegic child, especially when the palsy is incomplete in degree, is very liable to suffer fits of Convulsion, or partial spasm, the spasms generally affecting solely or chiefly the paralysed limbs. And not rarely the arm and the leg—most strikingly seen in the hand and the foot—or one side are the seats of occasional contractures, above the more or less continued rigidity.

Much has been said as to the immediate causes of the sequelæ of Convulsions in children. The turning point chiefly is this. Are they the results of the primary changes causing the fit, or of the secondary changes its disturbance induces? I consider their causes, after speaking of the first of the sequelæ, viz. hemiplegia, as that most definite one of the series, and the points at issue are clearer when stated with reference to it. Indeed, I believe that hemiplegia is the most important symptom for study in our attempts to find out what children’s convulsions, so often apparently causeless, really mean.

The generally held opinion is, that the fits are caused by functional disorder of the brain, and that any morbid appearances seen after death are due to the changes the paroxysm induces. I believe such local symptoms as hemiplegia show local changes, and I have little doubt that one focus of disease is often the cause both of the hemiplegic convulsion and of the hemiplegic paralysis. I do not mean that there is discernible disease in the brain in either; and indeed in young children, even after permanent hemiplegic paralysis, I have found nothing abnormal except in one case, in which the thalamus opticus was a little smaller than its fellow. But, so far as I know, microscopical observations on such matters have been few. In adults, there can be no question that one focus of discoverable organic disease is sometimes the cause of both a Convulsion and the hemiplegia that follows it.

In unilateral epileptiform seizures in adults, and in the paralysis which precedes or attends them, or remains when they are over, there
is not unfrequently discernible disease of the opposite hemisphere, but sometimes nothing wrong is discovered. Yet, whilst we see nothing, no one believes there is nothing to be seen, were our methods of looking more highly developed. In the total absence of any demonstrative evidence as to the direct causes of many of the cases of unilateral Convulsion and unilateral palsy in children, I would suggest as a basis for inquiry, that the plugging of very small vessels may give rise to, or permit, these symptoms, as I think it probably does sometimes in adults.*

Amaurosis will be considered in another part of this volume. With loss of speech, we may take in mental defects. I say take in, for, although language is a part of mind, we usually speak of its defects and of mental disorders as separate things. After attacks of Convulsions children are liable to lose their speech, and this without any obvious loss of power in the articulatory muscles, at least so far as we can tell by the share they take in eating and swallowing. They may be able to utter only one word or one syllable. This loss may be temporary, or it may be permanent. In most of the cases I have seen where the loss is permanent, the children become spiteful, vicious, and they have nearly always uncontrollable tempers. They are like brutes rather than like young human beings. Children may be left after Convulsion in the same general condition without loss of speech. These are the saddest cases, I think, in the whole range of our practice, for I do not speak of fits in idiots, but of idiocy following fits. In some cases there is gradual improvement. There are many varieties, from some vulgar coarseness of mind to a total absence of decency. In many cases a false sentiment induces parents to let their child's enfeebled mind grow as it lists, rather than put the child to the annoyance of vigilant discipline. And they ask us for drugs! Then in older children, the defect of speech may occur with little alteration of mind beyond slight eccentricity of temper. The defect of speech is not, I believe, the direct result of Convulsion, but is another result of the disease in the brain, be it what it may, which gives rise to, or permits, the attacks. It is indeed a rare sequel of Convulsions, and will attend a simple attack of hemiplegia—i.e. simple in this sense, that it is unaccompanied by Convulsion, or other evident symptoms. I may just observe that the association of defects of speech with symptoms pointing to disease of the left hemisphere is not so striking as it is in adults, but it will be found that defects of speech are more likely to occur with Convulsion and paralysis of the right than of the left side of the body. Then it is obvious that our study of an act like talking—the result of the particular education of certain wide

* Since writing this sentence, I have made an autopsy on the body of a young woman, 22 years of age, who had been hemiplegic of the left side after one series of fits since the age of about three years, and subject to frequent convulsions from the age of five or six. The right cerebral hemisphere was much smaller than the left, and the left arm and leg were smaller than the right arm and leg. I found, however, no disease beyond what the unilateral atrophy implies. I have to thank my friend Mr. Norton for permission to see this patient. Q 2
anatomical possibilities—will be much helped by a consideration of cases of damage of the right or the left side of the brain before either is educated, or during the process of education. Squinting has long been considered a common symptom of affection of the nervous system in childhood. But Helmholtz has shown that the most frequent cause of strabismus is a congenital defect in the eyeballs. It is found in those whose eyes are hypermetropic. Of course, a child may have strabismus, as an adult may, from paralysis of one or more of the muscles moving the globe. It is held, however, generally, that strabismus, when a nervous symptom, is a result of spasm of muscles. Yet neither paralysis nor spasm of one muscle—for instance of one internal or of one external rectus—will properly account for the common form of strabismus. If it be not due to hypermetropia, the existence of which it would be impossible to demonstrate in very young children without using the ophthalmoscope, it might be supposed to be due to disease of some central part, where the arrangement of fibres follows not the geographical supply of muscles from nerve trunks, but a physiological arrangement according to the use of various muscles in consent for particular movements. The principle seems to be the same in other nervous symptoms in children, as in essential paralysis and in contraction of the hand and the foot in infancy; to these I have already alluded. I cannot but think such affections point to disease attacking parts of the system which are not fully developed, or the muscles depending on which have not been brought long into coordinate action.

It need scarcely be said that cases are not considered here in which there are found such causes for the defect of speech as deafness at an early age. Here the occurrence of defect of speech is due simply to the fact that the child cannot by usual means be taught to make words. Besides, deafness—I exclude cases of organic disease of the ears—is not a common sequela of Convulsions, of any kind, at any age.

And here, when speaking of the local disease which causes these so-called complications, and which is grave enough sometimes to produce permanent palsy, I must allude to what we know of the morbid anatomy of children's convulsions, although this scarcely comes within the scope of my paper. It would be more correct to speak of what we do not know, since, admitting that there must be some change from health in the nervous system itself, which change causes the symptoms, as a rule nothing is found which is not found in children who have never had fits. Wilks, speaking of diseases of children, says: "We meet with a large number of cases where the post-mortem appearances are absolutely nothing; and where, indeed, we could scarcely expect to find it otherwise. We allude especially to cases of Convulsions in children where no morbid changes are discovered; and when we consider that a child may have several convulsive attacks and speedily recover, which only a degree more severe shall prove fatal, it is clear that no very great change could occur in an organ which would have perfectly recovered itself had the fit been only one degree less in
severity." Whilst it is true that nothing has yet been discovered, Dr. Wilks does not affirm that minute changes do not exist. Apparent recovery is no certain sign that the impairment of structure which has once permitted the fits does not remain, and will not allow them again when at some future time the system is hard pressed by violent emotions, by general failure of bodily power, or by sudden ill-health. Apparent recovery, however, would be a sign that no wide breaking-up of structure had happened. Now there are found at examination after death from Convulsions, differences in the quantities of serum and blood in the head, but these differences are quite as likely to be results of the fits as their causes. For my part, I think effusion of serum and congestion of the brain have but little to do in producing severe cerebral symptoms of any kind. Of course those cases are not in question, in which, possibly from obstruction to the vein of Galen, as by tumour of the vermis process of the cerebellum, there is immense effusion into the cerebral ventricles. Then the child may suffer fits from blows and from their effects, and the brain may be the seat of tumour or of abscess as in the adult, but as a rule nothing is found when children die in fits which can be considered as a special cause of them, nor is anything usually discovered when they die hemiplegic. Then it may be said that it would be simply impossible here to consider fits from such causes as cerebral abscess or tumours, or even their sequelae, such as paralysis of one or more cranial nerves. These last-named sequelae are rare under three years of age, and are obviously accidental accompaniments of Convulsion, and depend on the chance position of organic disease within the cranium.

This consideration of causes of damage leads us from the study of the muscular disturbance, &c.—the physiology—to the question of the circumstances under which fits may occur.

2. CLINICAL HISTORY.—We have spoken of the fits which children have, and now we speak of the different circumstances which lead to or occur with fits in individual children. We say circumstances, for, as we have just seen, we know nothing or very little of the immediate causes on which the fits really depend, i.e. of the pathological changes. This is the most utilitarian part of the subject, as it brings us nearer to a knowledge of the things to be done. It is far more important for treatment to seek this approximative evidence towards showing how the nervous system is suffering, than to study the convulsive attacks by which it outwardly shows its distress. For, strictly speaking, rational treatment of such a symptom is impossible. In short, whenever there is abnormal muscular action, whether it be a general Convulsion or a continuous contraction of the muscles of one limb, or an occasional jerk of the side of the face, it is clear that the nervous system is suffering; but it may be suffering little or much from all sorts of indirect causes, so that such symptoms have most varied meanings. To arrive at their value as warnings of particular
evils, we must give them as wide relations as possible with symptoms which show particular states of general health or ill-health, the age of the patient, &c. To talk generally of a rational treatment of Convulsions may be to talk with an appearance of decision and definiteness, but such talk is really vague and indefinite. It is like trying to fix the meaning for a word without knowing much of the sentence of which it forms part. As we learn nothing complete from a word by itself, so we learn nothing complete from the symptom Convulsion—nothing for rational treatment. Moreover, we do not, after the keenest search post mortem, get to know what the immediate temporary or permanent condition of the nervous system is, nor even, in many cases, what the causes—in any sense of the word cause—are; and therefore, although we can treat fits empirically, we cannot be said to treat Convulsions rationally. We have too often in medicine but empirical expedients of more or less value.

The following arrangement may perhaps be a convenient one for grouping cases. When called to a child on account of convulsive attack, we may find—

1. That the child is suffering from some slight and temporary thing, such as an overloaded stomach, the irritation of worms, or the irritation of teeth.

2. That the child is beginning to be generally ill, as, for instance, to have some exanthem or acute cerebral disorder.

3. That the fit is part of some chronic condition of general ill-health.

4. That the Convulsion is one of a series of symptoms, the result of coarse organic disease of the brain or of its membranes of a chronic kind, such as a tumour or abscess.

5. That the fits are of a series which, for want of better knowledge, we are obliged to call epileptic or epileptiform.

I cannot consider fits which occur in the course of acute diseases, nor do I speak of fits as a manner of dying. I speak chiefly of emergencies. Of course it is not pretended that the above arrangement is a classification. It is to guide our thoughts in investigating what a convulsive attack may possibly mean, and not to fetter us with preconceived notions to fit individual cases. For we shall find that many a case will refuse to be placed altogether under one of the headings. A classification of Convulsions is impossible; we have to adopt superficial arrangements like the above. I shall consider cases but generally with reference to each of these headings.

There are three chief points which enable us to decide to which of the five sets a convulsive seizure has most affinities. The points are, the age of the patient, the general health, and the way in which the fit comes on, whether suddenly or gradually; in the midst of apparently good general health, or with obvious ill-health. Of these, the state of health is the thing most important.

We may be told that the child was perfectly well until a Convulsion suddenly happened, and no doubt this is so, i.e. to all appearance, in some cases, although, in many, slight symptoms will have
been overlooked. Let us see what slight symptoms may lead up to that apparent good health or that obvious ill-health, with both of which Convulsions may happen.

Premontory Symptoms.—The premonitory symptoms may be considered as of two kinds, although of course the distinct consideration of each set must not lead to the separate consideration of either. One of these refers to what may be called the signs of physiological disturbances of function of the nervous system; whether these be local, as the slight twitchings of muscles—which show as certainly as a full Convulsion that the nervous system has been invaded or disturbed—or whether they be more general, as peevishness, want of sleep, and drowsiness. The chief of these symptoms have already been spoken of as far as is warrantable in an article on Convulsions, and it has been particularly pointed out that they are not to be considered as signs of approaching convulsive attacks alone; but that along with others they show how the child is going to be ill—they point to Convulsion as likely to be a striking symptom of the threatening illness. The longer these warnings have lasted, the more it would seem that the nervous system itself is affected—although perhaps at first secondarily to changes elsewhere—and that by a fault in its own intimate structure it had given rise to or permitted the fits. But if the warning symptoms were of the second class, of which I now come to speak, and especially if they were of shorter duration, the more one would think that the fit was a sign that the nervous system suffered with the rest of the body, and as the most excitable part of it. The second class of warning symptoms, perhaps occurring with those of the first, would be, such as increase of temperature, pain in the head, constipation, and vomiting. This brings us to the examination we should make of the patient after the above inquiries. We should strip the child, and examine carefully to see if, after all, the fit might not occur with overlooked or unheeded disease, such as bronchitis. In these investigations we may find almost anything, from, for instance, a few rales in the chest to a full pleural cavity. And it cannot be too much insisted on that the child's chest should be examined as a matter of course, whether there are special chest symptoms or not. But on Convulsions occurring in the course of acute disease I must not dwell here, and I speak only incidentally of those at the outset which may be the first symptoms to strike the attention of the patient's friends. It may be here remarked, however, that of course a Convulsion, or several, occurring in general diseases, does not necessarily mean that some particular diseased changes have occurred in the head, but quite as likely that the nervous system gives way as a part of one system suffering as a whole; it is but a prominent sign of a general failure. Yet a fit may, as in general tubercular disease, be the first symptom to show that there is actual disease in the head itself.

If we found the patient to be in general good health, so far as we could tell, we should try to find out if there were no such temporary cause for the fit, as over-eating, or fright, and we should search for
evidence of local irritations, such as the coming through of a tooth, or worms may produce, not forgetting such things as pins. I cannot think, for my part, that over-eating, the irritation of worms, &c., or any such local disturbances, are likely to bring on a fit in a child whose nervous system is really healthy. And when we find, after getting rid of such causes, that the fits cease, and the child gets into apparent good health, we should, I submit, bear in mind that a feeble, or we may call it an "excitable," nervous system has to be reared, and may again fail when it is next tried, although in a very different way. But if from the child's age, and other considerations, these local causes were not probable, and especially if the child had had slight seizures before, we should fear, although we could not be certain, that the attack would be followed by others, which, for want of more knowledge, might be called essential, or, as some would call them, epileptic. When technical terms are allowed to govern our thoughts and our acts, it is very important how we name a series of symptoms. One thing is perfectly certain, that epileptic fits in adults not rarely date from Convulsions in infancy. The connexion is shown now and then by straggling fits at intervals of months or years, or by uninterrupted continuity of attacks at fairly regular periods. I have no facts, and I know of none on record, to show how many infants keep well after getting through severe Convulsions, but of this I am certain—that attacks in infancy, from one which attracted little attention, thought to be "only the teeth," to a whole batch, are followed by epileptic fits near the age of seven, fourteen, or twenty. I may at least safely affirm, that after the first fit in the most apparently healthy child, we cannot make a certain prediction as to the child's future. If we venture to say the child will most likely get well, and keep well, we can never say safely that it is certain to do so. When the child has had many attacks, and especially attacks in series, we may infer from the fits having occurred at wide intervals, as of several days, weeks, or months, and from the patient being left in ordinary health after each fit (this especially when the child is above three years of age), that they will recur, or will reappear later in life. In reference to this it is important to ask if the child's near relatives have had nervous symptoms.

Every medical man can relate instances of fits, or of other symptoms of cerebral disease, in different members of one family. I have now under my care a girl eleven years of age, who has had fits from the age of six months. Her sister, three years of age, has had them from the age of one week; another sister, aged ten, from the age of four years; and a fourth, also a girl, aged eight, from the age of six years. Instances so striking are rare, and, for my part, I have less belief in the hereditariness of particular nervous diseases than most practitioners have. It is, I cannot but think, more important to ascertain whether the nervous system of either of the parents has suffered in any way, and even then the mere facts that they have had particular cerebral symptoms, such as hemiplegia or convulsive attacks, can have but a partial influence on our inferences. A child is not likely to
directly inherit a symptom like Convulsion, but may inherit a feeble nervous system, or perhaps feeble nervous tissue, with a constitution to match, and thus may indirectly inherit a symptom. More generally it is rather a question of inheriting tendencies to disease of certain tissues which may fail in many parts of the body, than tendencies to damages of organs, or to disorders of functions. And I may here especially say, that in cases of Convulsions it is more important for practical purposes to know if the child be born of phthisical parents, if it present symptoms of inherited taint, than if its father or mother had fits or paralysis. The fact that the father had hemiplegia from rupture of a cerebral blood-vessel, or that the mother had fits from a tumour growing from the dura mater, would not lead us to think a fit in their child was the result of hereditary fault in the nervous system. For the paralysis and the Convulsion were due to disease, not of nervous tissue, but of blood-vessels, and to tumours growing out of commoner tissue than the nervous. I by no means wish to speak dogmatically on this point, remembering that the young of guinea-pigs rendered epileptic by injury to the spinal cord are subject to fits (Brown-Séquard). The question is not a simple one, for it is said that of different tubercular families, some families are liable to tuberculous disease of the brain, and others to tuberculosis of the lungs. Yet tubercle in children very rarely indeed, scarcely ever, affects one organ only.

To return to the consideration of the possibly epileptic nature of the fits in a child we are called on to treat. Information as to the loss of consciousness is believed to be important; but it is not always easy in children to get precise information about it. A very young child has not much mind to lose. Arguing from analogy, I should not think a convulsive attack, even without loss of consciousness, in a child, unlikely to recur and be persistent, whether we are to call the fit epileptic, eclamptic, or essential. I do not think it profitable to discuss whether the fit is eclamptic or epileptic, and I have little faith that the facts as to loss of consciousness, limitation of the spasm, &c., will help us to predict whether the fits will continue to recur. In short, I do not believe one can in any case, at any age, be quite certain, when a person has had a fit, slight or severe, partial or general, one, two, or many, that the nervous system is not in that permanent state which will cause or permit convulsive attacks afterwards, and this, too, after apparent recovery. I would say this—begging the reader to observe that I do not say the converse—of cases in which a fit may have disappeared when a tooth has been helped through the gum. The nervous system, which has failed in this physiological crisis, will be likely to fail later in other struggles of life. In Convulsions, secondary to scarlet fever, we should have less to fear, when the

* I think Herbert Spencer's views on Heredity are the most satisfactory. We may understand, I submit, a transmission of Physiological Units, but not of damages to organs, nor of disorders of particular function. (See Herbert Spencer's Principles of Biology.)
immediate danger to life was over; but "genuine" epilepsy sometimes undoubtedly dates from convulsive attacks, not only those following in convalescence from, but from those occurring in the acute stage of, scarlet fever. These attacks are, I believe, generally one-sided.

Nor do I think it of scientific importance, when such complications as loss of speech or hemiplegia follow, to force our knowledge to such a conclusion as that they are the result of eclampsia or epilepsy. The important thing is to find out what state of what part of the brain produced the whole series of symptoms. We shall never arrive at this sort of knowledge if we let the too free use of such words as eclamptic, essential, and epileptic, by settling the whole matter, prevent our setting out on the journey. These words may, however, stand not for knowledge, but to mark where knowledge is wanted. It is, however, of extreme importance to describe the sort of Convulsion we witness, and the circumstances under which it occurs.

Let us now suppose the child to be obviously out of health; he might be so in two ways. (1.) He might present the symptoms of a temporary acute illness. There might be heat of skin, raised fontanelle, drowsiness, with fretfulness on being disturbed. Here we should fear that some acute illness, as smallpox or scarlet fever, was beginning, of which the Convulsion was the first prominent mark. It scarcely comes in my way to do more in this paper than urge the recognition of these rarer possibilities in the crowd of more probable causes. We should in all doubtful cases examine the urine. The presence of blood in the urine might show us whether the fits were or were not the result of masked scarlet fever. And more generally we require more observations on the condition of the urine in convulsive seizures soon after the attacks. Sir J. Simpson thinks a condition of which albuminuria is one of the signs, may give rise to fits in infants, and he found albumen in the urine of a child three days old, who suffered from Convulsions.

Then heat of skin and drowsiness may be thought to point to defect in the circulation from causes which primarily affect the head itself. This symptom, if it is to guide us in treatment, should be accurately estimated by the thermometer. A considerable increase of temperature should, and would, carry our thoughts away from the fit, and we should make investigations for many acute diseases. The history of scarlet fever in other members of the family would be a most important guide, and we must never fail to make inquiries for it, however suddenly the fit may have come on, in the most robust child. Dr. West mentions a case, no doubt scarlatinal, in which Convulsions, succeeded by coma, destroyed in a single day a healthy boy two years of age.

(2.) The child might be ill in a more chronic way. If we found the patient emaciated, or if he had diarrhoea, or dyspepsia, we should be ready to hope that the fit was but the sign that the nervous system was temporarily suffering with the rest of the body,
and we might fairly hope that it would cease to suffer when the child had been brought back to its usual health. Convulsions not unfrequently occur in infants who are imperfectly fed. Or the mother's milk may not suit the child, and, in these cases, there is often dyspepsia and diarrhœa, a big belly, with thinness of other parts. In these cases the Convulsion may be ascribed to cutting the teeth, or, especially when there is diarrhœa, to the irritation of the intestinal canal. These causes may have something to do in provoking the fit, but they cannot, I think, be solely to blame for it. Yet there can be no doubt as to the propriety of helping a tooth through if the gum be tense, swollen, or red; but to do this as a matter of routine is not held to be good practice—I say held to be, for I know that many practitioners, who have paid much attention to children's diseases, very rarely lance the gums. If a fit occurs after a meal, we may properly give an emetic. For my part I have, as I have said, but slight belief in such irritations being causes of fits, but I will now only deprecate exclusive attention to these supposed sources of external irritation. If fits do sometimes cease when a vermifuge brings away worms, or when the gums are lanced, we know that in either case they often continue when the system is freed from such cares, or at least when we have done all we can to get rid of them. With young practitioners, such causes are, I think, held to explain the fit so thoroughly that they may keep in the background the evidence the child's general state will afford.

As we shall see, we have too often to rely on empirical expedients. We are, to say the least, unauthorized to ascribe children's illnesses to the teeth, unless we have considered all other possible causes. And even when there are no other obvious causes we must not always infer relations between teething and the Convulsions. It is very important to bear in mind that there are numerous cases in which we can make out nothing as to the cause of the fit; and it hinders scientific progress to determine to conclude, simply because we are goaded to act. We must remember that there is something occurring in the child's system wider for thought than the fact that a tooth is working its way through a gum. The coming through of a tooth must be thought of as an outward mark of a certain constitutional progress, as the occurrence of menstruation is, later in life. It is far better to acknowledge that we cannot find out what causes a fit than to put it down to an orthodox cause in the want of a more real one. The healthy signs of developmental changes have not been enough correlated, and thus I think we exaggerate the effect of the most striking event of them. Then fright is followed by Convulsions, as by other signs of nervous disorder, such as choreal movements. Very likely fright is often but an exciting cause, yet an overwhelming terror may cause most serious symptoms in young children who are believed to be healthy.

Again, the presence of diarrhœa should not lead us to routine efforts at clearing out the bowels to get rid of undigested irritating matters. The careful dieting of the child is of very much more
moment. A child is at once overworked and underfed when it has to take into its stomach large masses of food it cannot digest or assimilate. It would indeed be a fatal mistake to consider the Convulsion in a child who is thin and who has diarrhoea as a sign of congested brain. It might be a sign of stagnation of blood in the head, but not of a process with any activity about it requiring antiphlogistic treatment. We do not know what the intracranial changes are which cause fits, and we have no evidence that active cerebral congestion occurs before the attacks. We have plenty of proof, from disease and experiments on animals, that Convulsions will follow anaemia, and clinical evidence that they occur in feeble children and in the course of exhausting diseases. It is, to speak in the most general terms, a fatal mistake to consider the most violent and dramatic Disorders of Function of the Nervous System to be, in themselves, the signs that there is anything like inflammation going on in the head. When Convulsions are frequent and severe it is intelligible, that some might very properly, on Markham's principle, apply leeches to relieve the congestion of the head, but not to reduce an inflammatory process. Shivering, heat of skin, would be better symptoms of rapid tissue changes than the most violent fit. I say again that repeated Convulsions are not the signs which should make us deplete, apply blisters, or give purgatives largely. Treatment on this hypothesis is admittedly a most fatal mistake in those cases where the fit is but the cry of starvation, as it undoubtedly is in many cases of diarrhoea, and in cases of wrong feeding. We may, it is true, put an end to the fits by depletory measures, for we may so far reduce life that function cannot exhibit itself even in a disorderly manner. But to treat the Convulsions that occur in a rickety, pot-bellied child as a rebellious assertion of vigour, is like quelling a bread riot by cannon and bayonets. And this relation of defective nutrition to disorder of function leads us to consider fits in batches; for it is when fits occur frequently, and are attended by insensibility, that we may be misled. A child may have a fit once a day, once a week, or have one or more at regular intervals; but now and then, just as occurs in adults, they may come on in such rapid succession, that the child lies in a condition, sometimes frequently broken by fits, varying from stupor to coma. The fits may repeat themselves rapidly for hours, so that many Convulsions seem like a single continuous seizure. But here again we must never consider the fits or the coma, however extreme, as signs that their cause in the brain is anything active. No one would consider the status epilepticus in an adult to be a sign of inflammation of the brain, and we ought not to think its corresponding state in the child to signify it.

Prognosis.—The prognosis of a symptom with so uncertain a meaning must, of course, be very uncertain, and much has been already said on prognosis. Here may be excluded from present consideration the attacks which precede or occur in the course of acute disease. The writers in separate articles will speak of the evil omen of such seizures.
CONVULSIONS. 237

When a child has got over a fit, and appears to be in good health again, the question as to the cause of the fits, with a view to forecast the child's future, becomes again urgent. If there is clear evidence of some source of irritation, and we have got rid of it, we may hope the child will get well, and perhaps keep well; but I have already spoken of the uncertainty of our hopes in this respect. I have no more to say here except to remark that the longer the intervals betwixt the attacks, the more likely are they to become naturalized in the system, and then to be called epileptic. And I have already said all I can say of the likelihood, or rather of the possibility, of defect of speech, idiocy, or paralysis remaining after Convulsions. To speak separately of prognosis, I could do little more than repeat what I have said from other points of view.

By far the most important thing is to know if the child is likely to get through a particular series of acute Convulsions with life. In the first place, a single attack may be fatal, but this is a rare event. Wilks relates two striking instances of rapid death with Convulsions. One was a small, delicate child, six weeks old, who was seized suddenly with diarrhoea and Convulsions, and died in a few hours. The other patient was a child four years old, strong and healthy, who died soon after being brought to the hospital. In neither case was anything wrong found with the brain; but in the child four years old the stomach was distended with food. Such cases, however, are rare, and when they occur our doubts are rapidly ended. The consideration of less acute seizures is more important. We can only deal in generalities. The more frequent or violent the seizures, the more profound the coma; and the worse the state of health in which the fits began, the more likely is the child to succumb. We must remember too, that, although very rarely, a child so long subject to fits that the parents have despaired of medical aid, and have made up their minds that nothing more can be done, may although in good general health, for aught we can tell, die in a severe attack after eating its dinner.* To study the ways in which fits are likely to bring about death is most important, and these will be mentioned with the treatment to which I now come.

Treatment.—It would not be correct, as I have remarked, to speak of any purely rational treatment of a single symptom, which means things very different. Our treatment is nearly altogether empirical. I, of course, exclude altogether from present consideration cases in which Convulsion occurs in such diseases as scarlet fever, meningitis, &c. Even an empirical treatment of Convulsion would not be justifiable in these instances. I have no doubt whatever that in time we shall cease

* I speak of a case I recently saw with Dr. Anthony Roberts. A child two years and two months old had had fits from the age of two months. After a seven weeks' interval, the child died in one. We found nothing whatever wrong beyond a very slight congestion of the lungs, and a large quantity of ill-cooked, undigested food in the stomach—none in the larynx, or trachea, or bronchi.
to consider any sort or degree of Convulsion as in any way a separate thing for diagnosis, prognosis, or treatment. Our thoughts on treatment would go hand in hand with our investigations, and of course principles of treatment apply to Convulsions of all sorts, from rolling of the eyes to complete seizures.

If we find the child in a fit, we should see that every part of its dress is loosened, that it has a plentiful supply of pure air, and we should direct that it be laid down, and be kept quiet.

If we find that the fit came on after eating, we should give an emetic of ipecacuanha. If a gum were swollen and tense, we might properly use the lancet. We should inquire after the state of the child's bowels; if they were constipated, we should give a purgative. But none of these things must be done as a matter of routine. The presence of diarrhoea, especially, with tenesmus and expulsion of nothing but mucus, may show that there is irritating matter in the intestinal canal, and it is then proper to give a dose of castor oil. This must be, however, only to make a starting point for careful dieting. The presence of abdominal pain and constipation in robust children may lead to the suspicion of retained feces. Diarrhoea, which is—paradoxical as it may seem at first glance—sometimes a sign of constipation, would not prevent the moderate administration of purgatives or enemata. For a child at the breast, an enema of an ounce of warm water or of thin gruel may be administered, at one year, two ounces. Very likely the diarrhoea is due to wrong feeding, and to diet the child would then be the most important thing to attend to. When the motions are very frequent, and if the child be thin and weak, we may try to check the diarrhoea by astringents, if proper dieting does not arrest it.

Warm baths are frequently used, and, when there is no great heat of skin, and no thoracic complication, the child may be put in a bath with the temperature of $95^\circ$ to $100^\circ$ Fahr. for from five to ten minutes. Under any circumstances the feet and legs may be immersed in hot water. Then mustard plasters—a mixture of mustard and flour—may be applied to the calves of the legs for ten or fifteen minutes.

When we have done all that immediate investigation prompts; when we have attended to the bowels, lanced the gums, ordered proper food, the Convulsions may persist, and may even increase in number, in spite of all our care, and we thus are urged to do something more.

It is then that the sort of Convulsion has its chief importance. There is in attacks of Convulsion a tendency to (1) death by exhaustion, from the frequency of the fits and want of sleep; (2) death from asphyxia, suddenly, from prolonged fixing of the chest walls, and gradually from slow congestion of the lungs. The latter is often rather a way of dying than a cause of death. Adults die from convulsive seizures in each of these two ways.

If the child were much exhausted by frequent fits, or if it were weak from the first; if it were thin, if it had long had diarrhoea, I
CONVULSIONS.

239

should look most carefully to its support; I should prescribe beef-tea or juice of meat in abundance. Nor should I hesitate to give stimulants. The symptoms that would guide me in most cases on this point would be the great frequency of short Convulsions, or constant startings, or other abnormal muscular actions. I hold that the object in treatment of disordered function of the brain is to produce sleep, and to accomplish this we should, I think, give support liberally; and, if this fail, stimulants freely. I have already spoken of the importance of recognising that disorder of function does not depend on tissue changes extreme enough to be classed as inflammatory. If the beef-tea or juice of meat were vomited, I should give milk with a little ice, and inject the tea or the juice.

Affusion with cold water has been advised, but this I should by no means adopt. Of course I speak of fits in which there is no general fever, and no sign of inflammation of the membranes. A thin, delicate child I should keep warm.

Then as to special drugs. Antispasmodics have been given, but I think the best antispasmodics are nutrients and stimulants when these can be taken and digested. It may be desirable to give an enema of assafetida, e. g. 20 to 30 minims of the tincture in an ounce of warm milk. A mixture containing hyoscyamus, two or three drops for the age of six weeks, may be given with peppermint water. The great point, however, is, I repeat, to get the child to sleep; and to do this, it is, I think, justifiable, simpler nutrients failing, to give stimulants freely. I should, however, be most wishful to give as much nutriment and as little stimulant as possible. Nor, of course, should I give wine because a child had a fit, but only when the child was feeble to begin with, or was exhausted by the frequency of the attacks, wearied too from imperfect sleep, and perhaps starving, because the friends had not given nutriment before we were called. Supposing nutrients and stimulants were taken and retained, and failed to stop the Convulsions and to procure sleep, I should then venture to give narcotics. In no case should I prescribe narcotics except when I had ascertained that the child had previously taken nutrients and stimulants, or unless the child was fairly vigorous to start with. In no case, at any age, would I give opiates when there was great excitement with little vigour. It is as hurtful to give opium at this extreme, as in the condition of brain which occurs with general febrile states, and which condition is supposed to be due to congestion. Nor would I give a narcotic more than once in twelve hours, and then I should give a decided dose, e.g. a quarter of a grain of Dover’s powder under the age of three months; half a grain to a year, and a grain to a year and a half. Chloroform has been used by Sir James Simpson, and, when the above ascending series of remedies has failed, this might be tried. Dr. West says: “In cases where deple-tion is inadmissible, where the Convulsions are not obviously due to organic disease of the brain, while they are both severe in their character and are returning with frequency, the inhalation of chloro-
form sometimes altogether arrests them." It is also, he says, of service in Convulsions of a more chronic kind. He tells us, however, that its effects are evanescent; he adds, that he has never seen mischief from its use. "It requires the constant presence in the house of some one competent to administer it."

Now I come to speak of the cases where the severity of the individual fits threatens death by asphyxia; or when in frequent fits with insensibility, from the state of the breathing, we fear the lungs are very much congested. Frequency of breathing in insensibility is always an unfavourable sign, the more so if it be irregular. Fits threatening death by asphyxia often occur in robust children; bleeding is sometimes advised for them. It is a remedy which has been urged by many writers, but does not seem to me likely to be of use in altering the condition on which the fits depend; but I have never tried it in any form, by leeches or otherwise. For I have no faith whatever that Convulsions depend on any increase of nutritive changes that we can arrest by taking blood out of the system. As it seems to me, the mass of evidence goes to show that spasm is a sign of enfeeblement of nervous matter. In some cases, as I have remarked, Convulsions occur in robust children, and here the proof that the symptom is a sign of enfeeblement of part of the nervous centres is not evident. There is in children's convulsions no certain evidence as to the pathological condition of nervous organs. It is, however, often evident enough in robust adults, as when epileptiform seizures follow on blows, and on breaking up of the brain by mechanical injury. It would, however, I think be good practice to relieve the venous system when the circulation is impeded by congestion of the lungs. Indeed, I think we neglect to bleed as often as we ought to do, on the principle Markham has laid down. I should be entirely guided by evidence from the colour of the lips and the state of respiration, and not by the heat of the skin or by shivering. However, difficulty of the respiration so great as these signs imply, would mark the advance of a fatal issue, and our treatment could only, I fear, be expected to delay it: when I did deplete, it would be by leeches only.

So far I have spoken on the supposition that the fits are frequent, and are running a rapid course, and are tending towards death by exhaustion or by asphyxia; but if the fits come on once every day, every other day, or once a week, and if from inability to discover what they really did mean,—i.e. if unassociated with debility, irritation of teeth, &c., we were obliged to call them epileptic or essential,—I should adopt the same treatment as for epilepsy in the adult, supposing of course all general indications fulfilled: I should give bromide of potassium, a quarter of a grain under six weeks, half a grain under three months, a grain above that age, and a grain additional for every year. Indeed the bromide is a most useful drug in chronic Convulsions from any cause, and in most cases—excepting temporary and acute states like uræmia—I should prescribe it when other remedies failed, whatever was the state of the child. Of course, the bromide is
CONVULSIONS.

241

a remedy for certain unknown conditions of nerve tissue, and not for Convulsions only; but it is probably a remedy for those slighter conditions of nerve tissue which cause or permit spasm of muscle, delirium, &c.

Convulsions in People Above Seven Years of Age.—In the consideration of Convulsions in children above seven years of age and in adults, I shall again treat Convulsion as an emergency, and try to show what meanings the symptom may have, not so much scientifically as for prognosis and immediate action. I must say, to begin with, that even in so narrow an inquiry the symptom has still a very vague meaning. The known circumstances of Convulsions, the morbid changes discovered in the nervous system after death, are, however, more numerous than those found in a child. I know of no satisfactory way of handling so loose a subject, except by considering from what clinical points the symptom Convulsion should be considered, and what we should do when we are called to some one in a fit. And, as we generally reach the patient when the fit is quite over, we must speak also of the coma that follows. Let us glance first at some of the various circumstances under which a fit may occur. The fit may be (1) one of ordinary epilepsy or an epileptiform seizure; (2) the convulsion may be due to uremia, (3) to cerebral hemorrhage; (4) it may occur after severe injury to the head, (5) or follow immediately rupture of cerebral aneurism; (6) it may be a symptom of intracranial disease, of disease so organic as tumors.

This classification is scientifically absurd, but it is convenient clinically. The different things are put together, because there is no means of distinguishing the paroxysm and coma—the things we see—brought about from one of these causes, from the paroxysm and coma due to some other, even when we are present when the patient is in a fit or immediately after, and generally we are not. Indeed, the difficulty of writing on one symptom is very great. I beg the reader to bear in mind that this paper does not pretend to consider the whole subject of Convulsion, but only the relation Convulsion has to immediate professional action.

Before speaking of particular varieties of Convulsions, I will allude to the significance of the size of the pupils. In severe convulsive attacks of all sorts the pupil is usually, not always, widely dilated in the paroxysm. The condition of the pupil is not a symptom of much value in helping us to find out, the nature or seat of the internal changes on which the outward phenomena depend. Indeed, for my part, I attach scarcely any importance to alterations in the size of pupils, unless the alterations be extreme. For this reason I shall say little or nothing of the symptom in this connexion.

It is very important to ask if the fit came on whilst eating, as there can be no question that choking is a cause of death in that rare event "death in an epileptic fit." Dr. Lalor has written a valuable monograph on this point, and I could myself relate a case in which I

VOL. II.
fear, even at the autopsy, this, the most probable cause of the patient's death, was overlooked.

I have, of course, nothing to say about epilepsy except on its diagnosis from Convulsion due to what I may call more fatal causes. Nor need I trouble the reader by telling him how to make a diagnosis when he can get a full and clear history of previous fits of epilepsy; but often when we are called to a patient in his first fit, or when we have no history of his case, we are in a grave difficulty. Let us see how the question stands as regards cerebral haemorrhage, giving, for the sake of stability, an arbitrary value to the term "epilepsy," or epileptiform seizure, making it include severe convulsive attacks with insensibility, which are liable to recur at intervals, usually without danger to life.

There is nothing in the paroxysm itself to tell us whether the Convulsion be due to cerebral haemorrhage or not. In both the tongue may be bitten; in both the attack may affect one side of the body only or chiefly; in both there may be hemiplegia after the attack: both may be followed by coma; in both consciousness may be restored after a fit, and in both the fit may recur at short intervals, e.g. two or three minutes or a quarter of or half an hour. Moreover, both may occur in people so young as twenty, although it is true that cerebral haemorrhage is rare under forty, while epilepsy is common in young people. Now for points of difference. The coma following a Convulsion in cerebral haemorrhage is generally more profound than that after an epileptic attack, and there is oftener stertor. The one-sidedness of the Convulsion, probably not in the severest Convulsions, is very common in epilepsy, and occurs more rarely after haemorrhage into the hemisphere. I speak, I had better say, of a first attack, and not of Convulsions following several days after effusion of blood in the brain. In epilepsy, when one-sided, the fit frequently begins by spasm of one hand or foot of that side, so as to constitute a warning. I do not know that so definite a warning of this kind ever precedes fits from severe cerebral haemorrhage. The one-sided paralysis occurs both in epilepsy and in Convulsion from cerebral haemorrhage, but is rarer after epileptiform fits, and more rapidly disappears. But then it sometimes continues for years or for life.

The reader will now observe, that the diagnosis betwixt epilepsy and cerebral haemorrhage, if it be made from the circumstances of the paroxysm and postparoxysmal condition, is a question of degrees of the same circumstances. The presence of albumen in the urine would help us to distinguish, and to this I shall allude later. But although a diagnosis frequently cannot be made from the phenomena we witness or hear of, we may often infer the true cause from such circumstances as the age of the patient, the place where he is found, &c. This is not, in a practical point of view, a distinction without a difference.

Some time ago, I was told that a man past middle age had died near my house in his first fit of epilepsy. I have good medical
authority that the attack was a regular epileptic fit. However much convulsive seizures may resemble the most striking of our described types of epilepsy, the paroxysm tells us nothing certain about the important wrong in the nervous system which is producing it. I predicted cerebral haemorrhage, and a clot was found in the brain at the autopsy. I should not now give so confident an opinion; I gave it because the most likely thing to cause death in a first fit in a man of middle age is cerebral haemorrhage. If this is to be called a diagnosis, any one would be right nine times out of ten, if, shutting his eyes to all other evidence, he diagnosed cerebral haemorrhage in every death of a man of middle age in a fit. But he would, as I shall shortly show, now and then make a painful mistake. It is, I think, beyond question the most difficult of all difficult diagnostic problems for a practitioner who has seen much, and who has his wits about him, to give a decided opinion as to what a first severe fit means, and to what it will lead. Any one who has found by large experience on what various possibilities of internal change the outward phenomenon, Convulsion, may depend, becomes cautious; and appears to the inexperienced to be "undecided." It is the symptom that is undecided. I should be wasting paper and printer's ink by merely putting together words about what a Convulsion generally means at different ages. I suppose I do the reader more service by making prominent the difficulties of diagnosis. And I ought to say that many of the events I relate are rare, but they are things which have actually happened in the experience of one person. We must, I speak earnestly on this matter, bear in mind that in not a few cases of convulsive seizures we cannot get to know the state of internal change on which the fit depends, and we cannot tell what further is likely to happen to the patient. Moreover, every pathologist knows that, after examinations of those who have died in a fit, we are often no wiser as to the causes of the seizures.

I am aware that some speak of epilepsy as a cause of cerebral haemorrhage, i.e. I suppose the column of blood being obstructed at the lungs, rupture of certain of the cerebral veins is believed to follow mechanically. This may be so, but I do not think it is. However, the questions whether cerebral haemorrhage produces epilepsy, or a fit of epilepsy cerebral haemorrhage, do not come prominently into consideration in the narrow way in which I must treat of one symptom.

Whilst I say that effusion of blood in the brain sometimes produces Convulsions, I say also that fatal Convulsions, of apparently the same sort, occur without any discoverable changes in the brain at all. And of course even large bleeding into one side of the brain may produce nothing but palsy and insensibility.

Yet, as I have said, although we are called to a patient in a fit, we generally see him when the fit is over; when he is quite sensible, partly so, or in coma, or even when dead; and thus the diagnosis is rather, what does quick recovery, or coma, or death after a severe
Convulsion, mean? This will again be referred to in the article on Cerebral Haemorrhage.

When the stupor has cleared away we may become easier in our minds as to the opinions we form. We should ask the patient or his friends if he has had any premonitory symptoms. But we know that both apoplexy and epilepsy are preceded by premonitory symptoms. The warnings of apoplexy are more vague and inconstant. As a rule, those of epilepsy keep to one character, and consist of local spasms and twitchings, unilateral numbness, or cramp, and of attacks of temporary vertigo, which vertigo differs from the more continuous muddled giddiness of patients who may have had little cerebral haemorrhages, and who are liable to have great ones. Slight attacks of cerebral haemorrhage leave unilateral numbness too, and frequently, slight thickness of speech and defect of sight. There are such general differences to help us, and if we heard that several of the latter sort of defects had come on suddenly without repetition, even if we found no albumen in the urine, the balance would incline to the diagnosis of cerebral haemorrhage. Then I have myself no hesitation in saying that the ophthalmoscope will often enable us to make a correct diagnosis. By finding the recognised signs of Bright’s disease of the retina and retinal haemorrhage, I felt warranted in excluding uræmia and epilepsy as causes of a unilateral seizure, with tongue-biting, followed by hemiplegia, in a woman twenty years of age, and in diagnosing cerebral haemorrhage, a large clot was found post mortem.

I will pursue the subject by relating, as a supplement to the above remarks, particular cases of Convulsion. And as we frequently do not cease to have to do with such cases when the patient is dead, I shall now speak also of the medico-legal aspect of the occurrence of death in a fit.

We cannot be at all sure, if a patient has had fits for months or years, that death will not occur in the next one. This, however, is an improbable possibility. If we find that a patient, especially a young patient, has unusual coma after even one fit, we should bear in mind, rare as such an event is, that the patient may be suffering, not from “cerebral surprise,” but from haemorrhage due to rupture of cerebral aneurism. Drs. Ogle and Murchison have drawn especial attention to the occurrence of epilepsy with aneurisms of the arteries of the brain. Facts as to the particular nature of the paroxysm to which cerebral aneurisms give rise have not yet been recorded. I think the probability of rupture of an aneurism would be great if, in a young person, there had been persistent partial hemiplegia, with occasional spasms of groups of the enfeebled muscles; but this is speculative. Death from rupture of cerebral aneurism occurs, however, in people past middle age, as the following instances show. These cases strikingly show how uncertain our knowledge is of the causes of Convulsions.

A year ago I made an autopsy, with Mr. Conolly, of Aldersgate Street, on a woman, about forty years of age, who had died in a few
minutes—four, her husband said—in a fit, believed to be like what she had had at frequent intervals for several years. We found rupture of an aneurism of the left middle cerebral artery. But a cerebral aneurism may only begin to give trouble shortly before it causes death. The other day I made a post mortem examination, with my friend Mr. Widdas, of the body of a man fifty-six years of age, who had been a patient under the care of Mr. Richardson, of Whitechapel. This patient’s cerebral ventricles we found full of blood, which had come from a rent in an aneurism, in the middle line of the hinder part of the circle of Willis, just at the divergence of the posterior cerebral arteries. This patient had had symptoms of vague import, but of increasing ill omen—of which symptoms three convulsive attacks were part, death occurring in the last—for one week only. Again, a cerebral aneurism may exist, and its rupture may kill a patient who has no previous fits. A woman, fifty years of age, died in a fit, from rupture of an aneurism of one middle cerebral artery, having had no known premonitory symptoms for more than half an hour before her death, and these were very vague. This patient I saw with Mr. Steggal.

Next, it must be very carefully kept in mind that, although nearly complete loss of consciousness between the fits, as a rule, points to epilepsy, restoration to sensibility sometimes happens when there is intracranial haemorrhage; and this, too, when there is no paralysis, i.e. no local paralysis, after the fit. This was well exemplified—I speak from notes supplied me by Dr. Woodman—in the case of a young patient under care of Mr. Gayton. A man twenty-four years of age died, rather suddenly, twelve hours after a fit of Convulsions. Although this man had recovered so as to take broth, and to answer questions correctly, his cerebral ventricles were found at the autopsy full of blood.

To consider this and other cases I relate, as cases of Convulsions only, is of course absurd; but this way of considering them is the only one in which they could be considered before the autopsy. To have diagnosed the true cause of the fit in Mr. Gayton's patient, at the time of his recovery from the coma, would have been, I submit, impossible in the present state of our knowledge; for the patient had had fair health, as far as was known, except for one fit in infancy; and the last fact would have misled, if it had had any influence at all on the diagnosis.

Even if we could exclude haemorrhage, we certainly cannot be sure that a series of fits (when the paroxysms resemble those of ordinary epilepsy), with perfect recovery between each attack, will not end fatally. A man, about fifty years of age, under the care of Dr. Anthony Roberts, of Lamb's Conduit Street, died after a fit—the third in an hour—although between the seizures he had quite recovered his consciousness, and, after the second attack, had said that he believed he had been poisoned. Now, in this patient’s body nothing whatever was found which could be called abnormal, and
an analysis discovered no poison. It was afterwards learned that the patient had had one fit before. In this case the man died in a fit; but why he had it, and why he died in it, is quite unknown. A little while before I saw this patient, I was called to a young, healthy-looking woman, who died in a fit, when at her work. It would be more correct to say, that she was found dead, after being missed for a short time; and, as she had been subject to fits for eighteen months, it was reasonably inferred that she died in one. I thought—and shortly before this occurred I had been right in giving this opinion in a case much like the one I am relating—that she had died of rupture of cerebral aneurism; but no sort of disease was found at the autopsy. Here, again, death occurred in an "epileptic fit." I saw, with Dr. Anthony Roberts, a woman, who was dead when I arrived at her house. She had just died in a general Convulsion, which Dr. Roberts had witnessed. She had eaten one of some mussels which she had prepared for her supper, and had taken a little beer. Soon after, she went downstairs to a friend, and said she felt "so ill" she should "go mad." A little brandy was got for her, but it gave no relief. She was carried upstairs, and then had a fit, and died in it, having been known to be ill only about twenty minutes altogether. This fit, her husband told me, was the only one she had ever had. We found nothing whatever wrong in this patient's body at the autopsy.

To say that these patients "died of epilepsy" is allowable, if this classification lead us to a consideration of the value of severe Convulsions in inducing death, or of dying causing fits, and is not rather permitted to stifle the uneasy questions that arise in our minds, when, after sudden Convulsions, ending quickly in death, nothing whatever is found to account for them. And while I would carefully estimate the amounts of serum and blood in the brain in every case, as I would any other positive facts, I should prefer not to dispose of the difficulties of the subject by attributing death after a fit to effusion of serum, or to congestion; for I do not think either of these conditions is likely to be a cause of Convulsion, or of death. It really is very important to bear in mind that we know little of even the remote causes of any sort of Convulsions; and in some cases we know nothing whatever, even when, after death, we have thoroughly searched every part of the body. The diagnosis of the cause of the Convulsions in the patient whose case I have related, was more than difficult. It was impossible, even after a careful post mortem examination, I should tell a coroner's jury that I had not discovered the cause of death, if I saw no more than congestion or effusion of serum; but I could say the patient died in a fit, and in a way which is well recognised, and which is usually unattended by suspicious circumstances.

I will now consider Convulsions from the point of uræmia, or rather clinically from cases in which albumen is found in the urine. Of course, uræmia does not uniformly include Convulsion. Convulsion is but an incident, in a series of which "quiet stupor" (Addison) may be one extreme, and profound coma the other. When a fit comes on
in a patient under our care for kidney-disease—as in a child, with dropsy or scarlet fever—these symptoms give us, as regards diagnosis, little trouble. But, in the following considerations, I suppose it is the patient’s first fit we see, or that we get no certain account of his former condition.

In all cases of Convulsions, we should examine the urine; but the presence of albumen would not enable us to say that the Convulsion was due to uræmia, nor its absence render it safe for us to conclude that it was not owing to kidney-disease. I will suppose, however, that we found albumen. In a young patient, blood and albumen in the urine would lead to inquiries for scarlet fever, however suddenly he might be taken ill. But the difficulty is chiefly with adults who are seized with Convulsions suddenly in the midst of apparent good health.

We must not attach too much importance to the presence of albumen in the urine. To conclude that Convulsions occurring in a person who had albuminous urine are uræmic would be clumsy, for cerebral hemorrhage often occurs in those who have granular kidney. Now, I know no means of distinguishing with certainty the Convulsions of uræmia and epilepsy from those of cerebral hemorrhage. Something, however, may be learned by considering (1) the state of the limbs when the Convulsion is over, and (2) the degree and nature of the Convulsion. The absence of paralysis would lead us to infer that the Convulsion was most probably either epileptiform or uræmic—in other words, that it was due to some central, or to some general cause. But as I shall have to mention in my other article, it is hard to say if there is any palsy at all when a clot in the pons paralyses both sides of the body. Suppose, however, we find the patient is comatose after the fit, and paralysed on one side of his body as to the limbs. If we find albumen in the urine, we may venture to exclude epilepsy—although of course disease of the kidney is not preventive of ordinary epilepsy—and we should think the patient had had an attack of cerebral hemorrhage. But unless the patient had recovered a good deal, we could not certainly tell whether the paralysis occurred after the fit, or was due to old cerebral disease. This brings me to speak of the sort of Convulsions. If the Convulsions were limited to one side, or nearly limited, or if they affected one side first, we should think they would doubtless be followed by hemiplegia, and would, if there were albumen in the urine, most likely point to a clot in the opposite side of the brain. We know, however, that paralysed limbs are subject to spasm, and patients with diseased kidneys, who have had hemiplegia from cerebral hemorrhage, are liable to convulsive attacks, and, in the cases I have seen, the paralysed side, i.e. as regards the limbs, has been the one that has most suffered, or that side has been affected alone. And it is important to bear in mind that patients hemiplegic from clot with diseased kidneys are liable to convulsive attacks, single or in batches, limited, or nearly limited, to the side of the body paralysed, and that these seizures do not necessarily, nor I
believe even usually, indicate fresh effusions of blood. Moreover, in such cases, even when the seizure is very severe, it must not make us conclude that it points to an immediately fatal issue.

The age of the patient is an important circumstance, but undue weight is, I think, attached to this point. It is impossible to be certain that—there being albumen in the urine—a young man or young woman who is seized with Convulsion during apparent good health, e.g. when at work, is not suffering from cerebral haemorrhage. We must estimate a patient's age by tissue changes, and not by the number of times he has been carried round the sun. This can be done by feeling his arteries, and by examining his eyes and his urine. Such examinations are by far more important than noting the sort of Convulsions; yet even they can give us no certain evidence. But I certainly think that convulsive attacks, followed by hemiplegia, in a young person must generally be put down to cerebral haemorrhage, if the patient has signs of general degeneration, such as rigid arteries, hypertrophy of the heart, and albuminous urine; above all, if he have retinal degeneration. We should learn something from the depth of the coma, but I am convinced that from this, soon after the fit, we learn nothing certain to show whether the Convulsion be due to cerebral hemorrhage, to uræmia, or to ordinary epilepsy. On the other hand, when the fits occur in batches, and the patient recovers betwixt them, we cannot be at all sure from this circumstance that they are epileptiform merely. Mr. Gayton's case, p. 245, shows this. I saw lately a patient who had had nine Convulsions one day, six fits during the following week, and who died in a Convulsion a fortnight later. This patient had been, I was told on good authority, quite sensible betwixt the attacks. He was, however, wandering when he came to the hospital. There was no albumen found in his urine. After death we discovered nothing wrong in the patient's brain, but his kidneys were small and very granular.

Dr. Roberts of Manchester remarks that in uræmic Convulsions in exceptional circumstances, the consciousness is not lost in the seizure itself. If we knew when the fit came on, we might, if there were any aura, incline to the belief that the fit was epileptiform. But, to quote Dr. Roberts again, "The incidents of the seizures [Convulsions in uræmia and epilepsy] are often identical even to the existence of an aura." Dr. Roberts adds, "As a rule, uræmic fits want the turgid purplish countenance and asphyxical character of true epilepsy—the face in uræmia being nearly always pale, and the breathing easy."

Another point of great importance in this connexion is as to the administration of poison. The question of opium poisoning, although very important as regards uræmia, will be far more satisfactorily considered with apoplexy of the pons Varolii. Dr. Richardson has related an excellent illustration of the simulation of uræmia by belladonna poisoning. In such instances the pupils will be widely dilated. Now, in all cases in which the pupils, except in the Convulsion itself, were widely dilated so as to reduce the irides to mere rims, I should
suspect poisoning by belladonna; I know of no circumstances, except belladonna poisoning, under which such extreme persistent dilatation of both pupils occurs. However, belladonna poisoning rarely produces Convulsions, but rather a kind of delirium, in which spectral illusions are created rapidly, and with some degree of coherence.

It may here be remarked that opium should be given with great caution—I would not myself give it at all—where there is believed to be granular disease of the kidney, as a slight dose might produce a poisonous effect. The sudden occurrence of extreme sleepiness, or of Convulsion after taking a dose of medicine, very naturally leads a patient or his friends to think there has been some mistake by the chemist, but these symptoms would lead the doctor to an examination of the patient's urine, and to a full consideration of the possibility of uremia. Except from such uncertain circumstances as the usually more gradual onset of drowsiness from uremia, and the circumstantial evidence that the patient has taken a dose of medicine, I could give no positive opinion as to whether the Convulsion or coma was hastened or produced by opium or not. To the condition of the pupils I attach but little importance here, or in most cases of Convulsion or coma. I believe the pupil is contracted in many cases of profound uremia, and indeed in all sleep-like conditions.

When, however, to omit poisoning, the patient came to himself, we should get from him an account of his previous paralysis, if he had had any, or of his previous general condition, if he had been ill before, to determine whether the fit was uremic or not. Or we may now, for the sake of illustration, suppose we have from the first a history from the patient's friends. If he had had headache, vomiting, and drowsiness; if he had had unusual dimness of sight, we should incline to the diagnosis of uremia. If he had had sudden local symptoms, such as decided unilateral numbness; if he had had sudden defect of sight, epistaxis, or sudden giddiness, and especially if there had been any defect of speech, or drawing of the face, as well perhaps as the more general symptoms, we should incline to the diagnosis of cerebral hemorrhage. But with granular disease of the kidney, both these series of events are likely to happen and to precede either uremia or cerebral hemorrhage. In many cases we must remain in doubt. Besides these difficulties, it cannot be too much kept in mind that in extreme granular disease of the kidney there is not always albumen in the urine. The absence of albumen does not then negative uremia, for it does not negative extreme kidney disease. It is needless to add that very great care should be taken in testing, and, as I think, Heller's test is the best for determining the presence of albumen when there is but a minute quantity in the urine. But the opportunities for testing the urine at all are not often afforded when we are called to a man in a fit; and, if we have to boil the urine in a spoon over a candle, we must remain in doubt when the change is not very conspicuous. When we have had the patient under our care for some time, we may determine these
points; we may find casts when albumen is temporarily absent, but then, for other reasons, the diagnosis will have become more easy. Perhaps there is actual suppression of urine. Then as to dropsy, there is rarely any considerable edema in patients with granular kidney who suffer cerebral haemorrhage, or who pass into a state of uremic coma.

Of the diagnosis of injuries to the head, I shall speak again in an article on Apoplexy. I have now only to urge, that when unusually profound coma follows a fit, even in an epileptic, we should consider the possibility of injury during the fall, even when the patient has not fallen from a height. A little while ago I made an autopsy on a man who had been for some time subject to fits, and who was seen to fall in one so as to strike his head violently. He died a few days after, and, at the autopsy, rupture of one middle meningeal artery was found, and this had allowed enormous effusion of blood.

Again, a Convulsion may be the first striking warning of disease of the brain so organic as tumours. For instance, a year ago I made a post mortem examination of a boy who died of intracranial cancer. This boy’s illness began by fits, and these were, for several months, the only symptoms to attract attention to organic disease of the brain. A sudden and violent epileptiform attack is, I hold, more frequently the first striking symptom of gross organic disease than is supposed. The fits will especially be found, or the history of them, in those cases in which the patient is blind from optic neuritis. Indeed, when called to a patient whose most striking symptom is Convulsion, we must consider carefully the condition of his sight, and such symptoms as vomiting and headache. I have known a fit, occurring suddenly in the midst of apparent health, followed by a few days of supposed recovery, to be the first symptom of a series ending in death. At the autopsy, a large tumour was found in the right cerebral hemisphere. Of fits occurring in the established course of those changes with which cerebral tumours are sometimes associated, it is needless to speak from my present standpoint.

In conclusion, let me say that I hope I have at least succeeded in illustrating the first sentence of this article. There is, indeed, no possibility of getting to know what a Convulsion means, unless the symptom be framed in a large general knowledge. And when, at the bedside of a convulsed patient, we have done all that the present state of scientific medicine enables us to do, we are often in doubt. As I have said, Convulsion is like a word in a sentence; taken alone, like a word cut out of a sentence, it has no intelligible meaning to us. To know what it means we have to study, so to speak, the etymology of many other symptoms, and, more than this, we have to bring to our studies a knowledge of the grammar of disease generally.
EPILEPSY.

By J. Russell Reynolds, M.D. F.R.C.P.

Definition.—Epilepsy is a chronic disease of which the characteristic symptom is a sudden trouble or loss of consciousness, this change being occasional and temporary, sometimes unattended by any evident muscular contraction, sometimes accompanied by partial spasm, and sometimes by general convulsion.

The two elements probably present in every case of Epilepsy are diminution of intelligence and excess of muscular contraction; and these two elements may exist in almost every variety of combination, and be developed to any degree of intensity. The latter element is not always seen to exist; there may be no spasm of the facial muscles, not the slightest change in the expression of countenance; or the face may become dull in aspect, or pale in colour, but consciousness is, for the moment, in absolute abeyance. There are reasons for thinking, as will be shown hereafter, that this loss of consciousness depends upon spasm affecting the vessels of the pia mater, but such spasm is hidden from our eyes. The former element, loss of consciousness, is that which is essential to our idea of Epilepsy: without its occurrence, no convulsion, however severe, should be regarded as epileptic; when it does occur, as a paroxysmal event, and with a chronic history, the case is one of Epilepsy, although no other symptom may be present.

There are two classes of errors into which authors have fallen with regard to the use of the word Epilepsy. The older mistake was to apply the term to every case in which there were convulsions, appearing in a certain form, called "epileptic," "epileptoid," or "epileptiform;" the modern error is to use the word to denote a paroxysmal—i.e. occasional and sudden—loss or diminution not only of consciousness, but of any function of any organ; or, indeed, sometimes to denote anything, or any condition, which occurs in a paroxysmal manner. The former led to the association, under one name, of diseases differing so widely from each other as tumour of the brain, Bright's disease of the kidney, intestinal entozoa, lead poisoning, and almost every form of malady: the latter might lead to the placing in one common group, and calling by one common name, such diseases as amaurosis, from dyspepsia, stammering, deafness, paralysis, or asthma. The former tendency led to the production of such words as renal epilepsy, symptomatic and sympathetic epilepsy, toxæmic epilepsy, and the
like: the latter has conducd to the coinage of such terms as epilepsy of the retina, acoustic epilepsy, and so forth.

There is, I think, a radical and very mischievous mistake in both of these modes of using words; the error is similar in the two, as far as regards its principle, but it differs in the detail of its development. The older authors exaggerated the importance of the form of a group of symptoms,—conversion,—occurring in a number of organs, and common to many widely different diseases: the modern have exalted into undue prominence the pathological significance of one element out of this group of symptoms,—viz. arrest of function,—which single element may occur in many diverse organs of the body. By such a word as "renal epilepsy" was meant a disease, resembling Epilepsy, but dependent upon, not an unhealthy condition of the nervous centres, but on an irritation of the kidney, or an altered blood-state which kidney-disease might have determined: by such words as "retinal epilepsy," something very different is intended, viz. a malady confined to the retina, in which a change takes place, supposed to be analogous to that occurring in the brain in Epilepsy. In the one Epilepsy merely means convulsion; in the other it merely means arrest of function; and the objection I entertain to such use of terms is based upon the fact that, however widely different individual cases of Epilepsy may be, they do yet belong to a group which has a definite clinical history, and which has had it for some hundreds of years. If good reason can be shown for getting rid of the word "epilepsy," I should rejoice to lose it from our nosology; but so long as the word is retained at all it should have a definite and intelligible meaning. Renal asthma would be a term as pathologically correct as "renal epilepsy:" dyspnoea of the fingers as justifiable as the expression "epilepsy of the retina."

**SYNONYMS.**—No useful end would be served by enumerating all the names by which this disease has been described, inasmuch as many of them have fallen into complete disuse. The most important are the following:—

Epilepsy (English); l'Épilepsie (French); Fallsucht (German); Mal Caduco (Italian); Epileptica passio, Morbus sacer, M. comitialis (Latin); 'Επιλῆψια, 'Επιλήψις (Greek).

**NATURAL HISTORY. 1. GENERAL PREVALENCE OF THE DISEASE.**—
Epilepsy is spoken of as a very common affection. Niemeyer states that in every thousand individuals there are to be found six epileptics.* Such statement cannot, I think, be true with regard to Epilepsy in this country; for among 1820 invalids, whose cases were recorded by myself as out-patients of the Westminster Hospital, there were only seven epileptics; and but thirty-four whose diseases could, by any possibility, be confounded with Epilepsy. It must be observed further that Niemeyer is speaking of individuals generally, and that the results

* Niemeyer, Handbuch der speciellen Pathologie, p. 637.
of my own examination at the Westminster Hospital are obtained from a small class of individuals, viz. those who are ill.

The proportion of true Epilepsy to other diseases of the nervous system has been found to be about 7 per cent.

2. CAUSES OF EPILEPSY. (a) Predisposing Causes.—Hereditary taint has been found to exist in rather less than one-third of those cases which have fallen under my care, and have been carefully examined on this point. It is not intended by this statement to affirm that true Epilepsy has existed in the parents of one-third of the cases; but that some disease of the nervous system, more or less closely allied to that under consideration, has been present in either the parents, the grand-parents, the aunts, uncles, brothers, or sisters; that there has been a family proclivity to nervous disorder, in one case showing itself by idiocy, in another by mania, in a third by convulsions, and so forth. I have found only 12 per cent. of epileptics giving a distinct history of Epilepsy in other members of their families; a number which is very near to that stated by Dr. Sieveking, and not far removed from that given by M. Delasauve.

It has been said that the disease is more frequently transmitted on the fathers' than on the mothers' side,* but the reverse of this proposition has been found to obtain in cases examined by myself.

Of 130 epileptics I found 80, or 61·06 per cent. who asserted the entire absence from their families of any predisposition to nervous disease; and 8 individuals, or 6·10 per cent. who were in some uncertainty as to the health of important relatives. These patients were derived from all classes of society; and I have no means of determining the question, on a scale sufficiently large to be satisfactory, whether Epilepsy is more commonly found to be hereditary in the upper, the middle, or the lower classes. Several elements of doubt enter into the solution of this question, the most important of which is the greater difficulty that is encountered in obtaining accurately the facts which belong to the latter. Hospital patients often know but little of their antecedent or even collateral relations. Among the upper classes there is not rarely a studious concealment of what are regarded as prejudicial family conditions. The middle classes are not only more accurate than the former, but more free than the latter; and, judging from what I have gathered from them, as they shade off on either side,—above them and below,—I should be of opinion that hereditary taint is more frequently discoverable in the better conditions of life than in the poorer. It is not intended that there are absolutely a larger number of hereditary epileptics among the former than the latter; but that of an equal number of epileptics in the two extremes of society, a larger proportion will furnish evidence of hereditary taint among the rich, than among those who are in want. This is probably due to the fact that the latter class are exposed more frequently and

more severely than are the former to the most active determining causes of the disease, viz. anxiety, alarm, and want.

Sex.—Little that is of value can be shown with regard to the influence of sex as a predisposing cause of Epilepsy. Practically, the two sexes appear to be about equally affected; and the different statements that have been made by various authors,—some of whom represent the male sex, others the female sex, as the more liable to the disease,—may probably be accounted for by other circumstances than that supposed, viz. a special sexual predisposition. The relative number of female epileptics who are out-patients of Hospitals, may be determined by the hours at which the physicians make their visits, or by other conditions which have to do with the social position of the applicants, and which may render it easy, difficult, or almost impossible for either the one or the other sex to attend.

Similar degrees of fallacy, although different in kind, may influence the results obtained from private practice. The facts of a physician's age, and single or married condition, for example, might exert an influence upon the relative numbers of his male and female patients too great to be counterbalanced by proclivity to Epilepsy inherent in either sex.

Again, the statistics gathered from asylums are liable to disturbing causes so far as aetiology is concerned. In proportion to the amount of disease a larger number of males than females find their way into public asylums. The reason for this is obvious, viz. that men are prevented from doing their special work in the world by an amount of disease which need not deter women from performing their domestic duties. Yet further, the statistics furnished on this point by some authors are complicated by limitations as to age, and by the fact of, more or less clearly pronounced, insanity of mind.

Little, then, that is definite can be stated on the influence of sex, as a predisponent to Epilepsy; and it seems to me to be the wisest course at present to leave the question open for further investigation.

Age.—The influence of age in the production of Epilepsy is strongly marked. This is shown in the following short table of cases collected by myself:

<table>
<thead>
<tr>
<th>Age at commencement</th>
<th>Males</th>
<th>Females</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Under 10 years</td>
<td>10</td>

<td><strong>70</strong></td>
<td><strong>172</strong></td>
</tr>
</tbody>
</table>

The most important fact to be recognised in the above summary is the great frequency with which Epilepsy commences between 10 and 20 years of age; i.e. at a period of life embracing the processes of the second dentition and of the establishment of puberty; and, without going much further into detail, it may be stated in addition, that by far the larger number of the group showed their first symptoms of
the disease between the ages of thirteen and seventeen years, inclusive. Further, that there is a comparative immunity from attack between twenty-five and thirty-five, the greater proportion of cases forming the third group having been seized by the disease at or about the age of forty.*

When there is a marked hereditary taint as a predisposing cause of Epilepsy, the disease is found to develop itself somewhat earlier than under other circumstances. The difference, however, is not so great as that which is to be observed in regard of some other maladies which are held to be hereditary. The difference may be fairly represented in the following table:—

Commencing under age 15 . . . 83·33 hereditary 46·15 non-hereditary.
above , . . 16·66 , , 53·82 ,

It has appeared, further, that when Epilepsy is hereditary it shows itself at an earlier age among girls than among boys.

(b) Accidental or Exciting Causes.—Patients and their friends often exhibit a very great anxiety to refer the outbreak of Epilepsy to some external condition, which they may speak of as its cause; and, in doing so, they occasionally attach undue importance to trivial circumstances. There is a natural reluctance to admit the presence of constitutional, or hereditary taint; and an eagerness to find excuses for the poor sufferer, in the fact of his having been exposed to some extraordinary disturbance from without. In this way we may, in some measure, account for the wideness of the range of conditions to which the production of Epilepsy has been referred. It is so difficult to conceive that a disease having such strongly-marked features as those of the epileptic paroxysm, can lurk in an apparently healthy frame—that all the essential conditions of so terrible a malady may be present and yet give no sign—that many find an explanation of the outburst in some externally disturbing cause which they can appreciate, and ignore the operation of those internal conditions, which had hitherto escaped their notice, or had been regarded from a different point of view.

It is important to classify the causes to which Epilepsy has been referred, and I have done so by distributing them into four groups; placing in the first, those which operated through the mind or the emotions, such as fright, grief, worry, and the like; in the second, those which acted through the reflective centre, such as eccentric irritations; in the third those which produced their effect through changes in the general health, such as those which may be occasioned by pregnancy, by acute specific or other diseases; and in the fourth, those which may be regarded as acting physically, such as insolation, mechanical

* For further information on these points the reader is referred to Hasse, in Virchow's Handbuch, 1ster Abth. 4ter Bd. p. 264; Reynolds, on Epilepsy, p. 126; Leuret, Archiv. Gén. de Méd. 4me. Série, 1843, t. ii.; Sieveking, Med.-Chir. Trans. vol. xl. p. 158; Herpin, Du Pronostic, &c. p. 332. It is, however, to be remembered that in the case of some of the authors referred to care has not been taken to separate Epilepsy from other convulsive diseases.
injury, and the like. It is difficult to determine into which category of causation some cases should be placed; as for example those in which the fits have been referred to either falls, or blows, inasmuch as it is possible that such accidents may have operated through the mind by alarm or fear, rather than through the body by the merely physical process of concussion or laceration. I have placed such cases into those groups to which they had been assigned by the patients or their friends at the time that the disease began.

The following table exhibits the relative frequency of the several kinds of causes to which I have referred:

<table>
<thead>
<tr>
<th>Nature of cause</th>
<th>Number of cases</th>

</tbody>
</table>

Besides these sixty-three cases, I have the records of sixty-one cases in which no cause could be assigned; the patients or their friends either asserting their absolute inability to make any reasonable conjecture on the matter, or hazarding some explanation which was utterly nonsensical. It is important to know that of these sixty-one, there were forty-three individuals who, after examination and cross-examination, and suggestion, could give neither to themselves nor to me any clue to the solution of the mystery. Of 124 cases, therefore, sixty-three, rather more than the half, supposed that they could explain the causation of their malady; forty-three, or thirty-four per cent. asserted their utter inability to do so; while twenty-nine, or twenty-three per cent. referred their attacks to mental or emotional disturbance.

The frequency with which mental or emotional disturbance has been shown to be the cause of Epilepsy is such that it requires some further notice. The most common conditions that I have witnessed are those of continued anxiety, and prolonged rather than intense alarm. I have in a very few instances found that an over-strain of the mental powers has been followed by Epilepsy, but in almost every one of these cases there has been considerable anxiety as well, and it, I believe, has been the more efficient factor of the malady. Women and girls have much more frequently than have either men or boys referred their attacks to emotional disturbances; the proportion being thirty-six per cent. of females, and thirteen per cent. of males. The period at which the first attack has occurred after an individual has received some great mental shock varies widely; the fit may take place at the moment of alarm, or it may follow after an interval of hours, days, or weeks.

With regard to eccentric irritations it must be remembered that in the list given above cases of "convulsions" are not enumerated. Both the first and the second dentition, and even the cutting of the
"wisdom teeth," may be attended by convulsions, which in the large majority of cases disappear as soon as the source of annoyance has been removed. In a few rare cases, however, the processes referred to have appeared to cause genuine Epilepsy, and it is to these rare cases that reference is made. It is curious to know that in not more than half of the cases of Epilepsy can it be ascertained that "fits" have occurred during infancy; and it is a still more interesting fact that epileptic women appear to exhibit no high degree of proclivity to puerperal convulsions. Dr. Tyler Smith states that puerperal convulsions occurred only twice in fifty-three deliveries of fifteen epileptic women;* and so far as my own experience extends, it is exceedingly rare, and indeed almost unknown, for epileptic women to suffer from their attacks during, or immediately after labour.

Among the second group of causes, appears one to which, I believe, far too great an amount of importance has been attached, viz. excessive venery, or masturbation. It is very common to hear suspicions expressed upon this point; much more common, I think, than to hear any such statement of facts as should prove that Epilepsy and masturbation have any special character or frequency of relation to one another. The one is a tolerably prevalent disease, the other a very widely distributed vice. There are multitudes of epileptics with regard to whom no such suspicion could ever be entertained; and there are, it is to be feared, much larger multitudes of masturbators who have never become epileptic. When, therefore, we find the two elements combined in the same individual, it is necessary to observe some caution in our attempt to interpret their relations. It is, I believe, sufficiently well proved to be regarded as a fact that the vice referred to is liable to induce various disturbances in the health, and that the major part of these are brought about by, and are exhibited in, the altered functions of the nervous system; but what it appears to me is yet wanting in proof is the special relationship of Epilepsy to this particular wickedness, or weakness. Again and again it has occurred to me to see cases of vague, and various nervous derangements which might be fairly inferred to be the result of masturbation; but it has in only an exceedingly small number of cases of Epilepsy been possible for me to establish the existence of such relation.

There can, I think, be no doubt whatever as to the existence of an intimate association between various forms of nervous malady and either various abnormal conditions of the sexual organs, or unnatural circumstances attending upon their exercise; but, as yet, the nature of that association is, I believe, and as undoubtedly, unexplained. Sometimes physical excess, and sometimes the reverse; now, great emotional involvement, and now the entire absence of all sympathy; at one time exuberant enjoyment, and at another disappointment, or disgust, are conditions met with in epileptics, and in all forms of many sorts of disease; but, so far as I know, neither one of those conditions

is more frequent than another in the history of epileptics. I have
known cases in which morbid libidinousness occurred in epileptics, but
only long after the development of the disease; and, on the other
hand, I have met with cases where the sexual propensity had become
diminished, or even extinct, after the occurrence of the attacks, and
this without any previous excess in its gratification.

In endeavouring to determine this question, which is of considerable
aetiological interest, it would be undesirable to omit notice of the
striking effects which have been observed to follow the administration
of bromide of potassium in cases of Epilepsy. It cannot be doubted
that this medicine is highly valuable in diminishing the numbers of
attacks; * and the only point of interest to us now is to ascertain
whether its modus operandi is such that it either countenances or dis-
countenances the prevalent belief with regard to the aetiological
question under consideration. When this medicine was first intro-
duced by Sir Charles Locock,† it was recommended as being of especial
service in those cases of Epilepsy in women in which the attacks occurred
only during the menstrual period; and since that time it has been very
generally received that bromide of potassium possesses strong antaphro-
disiac properties, and that its utility in Epilepsy is to be accounted
for by its special action upon the generative organs. From the very
first I saw reason to doubt this mode of explanation,‡ and much
enlarged experience has, from my own mind, removed all doubt whatever
upon the point, and produced a settled conviction that bromide of
potassium, when given in such doses as to be of service in Epilepsy—
viz. from 10 to 40 grains either three or four times daily—exerts no
recognisable influence upon either the sexual propensity or power. It
is not asserted that doses might not be given so large as to exert such
influence, but that where decidedly remedial effects have been pro-
duced in Epilepsy, their production has not been attended by any
change in the generative functions. Dr. Duckworth Williams§ says,
"I have tried it (KBr.) in every variety of uterine affection that has
come within my reach, including nymphomania, satyriasis, menorrhagia,
amenorrhea, dysmenorrhea, &c. &c., but without perceiving the least
benefit accrue." Dr. Williams mentions cases in which the patients,
in spite of their taking the medicine, "persisted in their bad habits,
and their sensuality became if possible more confirmed." (p. 17); and
his experience on this matter is in entire accordance with the results
of my own observations. We cannot, therefore, support the prevalent
creed in regard of one mode in which Epilepsy is produced by facts
gathered from the treatment of that disease by bromide of potassium.

To what degree the view to which I refer is supported by the
recently published observations of Mr. Baker Brown,‖ must depend

* See p. 280 on Treatment, and also Dr. S. W. Duckworth Williams' Paper "On the
Efficacy of the Bromide of Potassium in Epilepsy and certain Psychical Affections."
‡ See Author, on Epilepsy, p. 332.
§ Loc. cit. p. 16.
‖ On certain Forms of Insanity, Epilepsy, Catalepsy, and Hysteria in Females.
partly upon the therapeutic results of his mode of treatment, and partly upon the interpretation which must be given to the alleged facts. On the former point the evidence is unsatisfactory, being gathered from a small, and too exclusive selection of cases; * on the latter point some misconception is possible. Considered etiologically, we want to know the proportion of cases in which the particular cause to which Mr. Brown refers had been in operation, but upon this point we are not furnished with any evidence whatever; inasmuch as in all the cases he records not only was irritation of the pudendal nerves believed to exist, but a certain kind of operation was performed. It would, I think, be pushing much too far the inference to be drawn from Mr. Brown's little book, to assert that his opinion is that every case of Epilepsy is produced in the manner described. What we want to know is the number of cases of Epilepsy in which Mr. Brown entertained no such suspicion, and still further, the number of cases in which having entertained it, and acted upon it, the result was unsatisfactory. As to the interpretation of the facts that are stated, there is this to be borne in mind, that so far as I can understand Mr. Brown's theory it is not that in such cases there have been, of necessity, immodest wishes, excessive sensuality, or irregular practices, but that there has been a morbid condition of irritability of a certain nerve, and that this has been taken away by the removal of the peripheral termination of the nerve. Referring for future consideration the question of the therapeutic propriety or desirability of the operation of clitoridectomy, † all that it is necessary to say now is that—in the absence of any definite statement of Mr. Brown upon the question of proportion as described above—my own experience would lead me to believe that the cause he refers to is of very rare and very exceptional occurrence.

In another work ‡ I took some pains to show how extremely rare it was to meet with a case of Epilepsy in which no causative conditions could be discovered. Although in one person we might find no predisposing cause, and in another no exciting cause, in only one-eighth of the cases was there an absence of both. In seven-eighths, either one, two, three, or more causative conditions of disturbance were present and were recognised.

The proportion, therefore, of cases of Epilepsy in which the causation of the disease is placed beyond explanation by our present knowledge of pathology, is not greater than that which we meet with in many other chronic diseases, and is far less than that which is admitted to exist in several. There is some mystery in the causation of almost all diseases; I do not think that it is greater in the case of Epilepsy than in that of many others with regard to which we think ourselves on easy terms with the science of pathology.

3. Symptoms.—It will be convenient to consider those which occur

* See Treatment, p. 253.
† See p. 283.
‡ Author, on Epilepsy, p. 261.
in, and constitute a paroxysm of Epilepsy, separately from such as may be observed during the intervals of attack. We have, therefore, to describe first:—

The Paroxysmal Symptoms, or features of the attack. In the most characteristic cases of Epilepsy there is an entire loss of consciousness in conjunction with a peculiar series of involuntary muscular movements; but, on the one side of these typical cases, we see epileptics in whom the loss of consciousness is alone obvious, and, on the other, individuals exhibiting certain highly-marked spasmodic phenomena, and only very slight or even imperceptible obscuration of the mind. It is necessary, therefore, to classify cases, in order to render description possible, and it is proposed to do so by dividing them into four groups, which may be thus distinguished. First, those in which there is loss of consciousness without evident spasm; second, those in which such loss of consciousness is accompanied by local spasmodic movement; third, those in which it is attended by general tonic and clonic convulsion, following a particular order; and fourth, those in which general or partial convulsion occurs without complete loss of consciousness. The first and second forms may be termed "epilepsia mitior," or "le petit mal;" the third form "epilepsia gravior," or "le haut mal;" and the fourth "epilepsia abortiva," or irregular Epilepsy.

(a) Epilepsia Mitior, or "Le Petit Mal," without evident Spasm.—All that occurs, and can be positively attested in cases of this description, is a sudden, temporary, but absolute arrest of both perception and volition. The individual so attacked loses consciousness, for two, three, or more seconds; and may after that or a longer period resume his sentence or employment, perfectly unaware that anything abnormal has happened.

Sometimes there is slight loss of balance—the patient, if standing or walking, leans to one side, or staggers, but does not fall; sometimes there is pallor of the countenance followed by slight flushing; sometimes the latter without the former; sometimes there is slight dilatation of the pupil, and an absence of the expression of "looking at anything;" sometimes an irregularity and faltering of the pulse; but often, as I can testify from repeated observations, there is not any one of the physical changes I have mentioned; the patient's mind becomes a blank for a few seconds, and that is all that can be observed.

These seizures are often regarded as "fainting," and are described by patients under various terms, such as "blanks," "forgets," "faints," "sensations," "absences," "darknesses," &c. &c.

Occasionally these slight attacks are preceded by vertigo; the patient thinks that he shall fall, and so lies down to avoid doing so; sometimes he staggers and grasps an object for support; but much more commonly, he simply ceases to perform any act requiring volition—he stops speaking or writing; but the automatic movements of standing, or sitting, and the secondarily automatic movements of riding, walking, or holding an object, are maintained.
Sometimes the attack is followed, for a few seconds or for a longer period, by an obscured state of intelligence; the patient speaks in reply to what is asked of him, but in half an hour afterwards is found to have entirely forgotten what was said to him or by him. In more rare cases the mind is dull, or altered from its habitual condition for a period of some hours, the patient being low-spirited, or suspicious, and apparently labouring under some delusion which he afterwards forgets. In this condition he may be listless; or he may do some odd things which he cannot afterwards account for, or even recollect.

(b) Epilepsia Mitior with evident Spasm.—This is more common than the preceding, which it resembles exactly so far as the mental condition is concerned. The extent and locality of the spasm differ widely in different cases, and also in the same individual at different times. There may be only slight strabismus, or drawing of the mouth, partial turning of the head to one side, or some movement as of swallowing or attempts at getting something from the mouth; or, on the other hand, there may be slight, momentary rigidity of the whole body. Sometimes the patient fixes his chest walls, and appears to "hold his breath;" sometimes he does some curious thing, such as stoop down to peep under a sofa, lie down and pull off his cravat, jump from his chair and walk quickly half-way across a room; but in any or all of these apparent attempts to do something he is suddenly arrested by the loss of consciousness, which is often absolute. It has never occurred to me to find an epileptic who could tell me why he did these things, or who could even remember that he had done them.

As to the locality of the muscles affected, it would appear that those of "expression" and of respiration are by far the most frequently involved. There is no evidence to show that either "trachelismus" * or "laryngismus," or "phlebismus" occur with anything like such frequency as to make them of any value in the interpretation of the epileptic paroxysm; although it is quite clear that the former may exist to such a degree as to occasion duskiness of the face.

The spasm in "le petit mal" is never violent; and it is only of short duration. It is tonic in its character, and painless to the patient, and the vascular changes which may be observed are of the same variable degree and kind as those enumerated in the previous section. Patients sometimes have warning sensations of these attacks, and I have known more than one instance in which there was a highly marked and most painful "aura epileptica."†

The most common combination and degree of symptoms may be thus described,—a feeling of giddiness, faintness, or discomfort; slight twisting of the neck, with anxious, lachrymose expression of the face, dilatation of the pupils, and pallor; accompanied, or quickly followed, by entire loss of consciousness, which lasts for two or three seconds; the patient "becoming himself again" after making a few sighing sounds, but feeling faint and bewildered, and often perspiring freely.

† See p. 263.
(c) Epilepsia Gravior, or "Le Haut Mal." This, the ordinary form of Epilepsy, is in the vast majority of cases characterised by complete loss of consciousness, and a peculiar combination and series of spasmodic movements. In very rare instances we have the latter element without the former; the more common and much larger group shall be described first, and it will be convenient to enumerate separately the premonitory symptoms, those of the attack, and the immediate sequelae, or after-symptoms.

Premonitory symptoms are sometimes absent altogether; in certain cases they are of regular occurrence, being in the same individual invariable in character, while in another set of cases they are sometimes absent and sometimes present, and are more or less variable in their features. Their duration may be almost momentary, it may extend to several minutes, or, but very rarely, to hours, or even days. When of long duration, the prodromata are diminished in speciality and in intensity; and consist, so far as I have seen, in some mental change, or in some alteration of the general appearance. Thus, there may be an exaggeration of any habitual condition of the mind or spirits; the patient becoming, to an unusual degree, depressed, morose, or taciturn; or, on the other hand, lively, irritable, and excited. I have known several instances in which an undue flow of spirits, and an emphatic frivolity and expression of "feeling remarkably well," have almost invariably preceded the epileptic paroxysms. Such sensations have occurred in those patients whose attacks were not of very frequent repetition. It is very difficult to describe those changes in general appearance, or in "the looks" of a man, which friends recognise as premonitory of an attack. Generally, I believe, they depend upon an alteration in the colour of the skin, and some want of fineness in the outline of the features. The face becomes less red, more yellow, and somewhat dusky in tint, and there is a certain puffiness which, without altering in kind, diminishes in force its habitual expression. It is said, "he seems quite himself, but he does not look so; he is sharp enough, but looks stupid; and we know that an attack is coming on." There is no œdema, but there is a partial obliteration of the lines which make up "expression."

Those symptoms which immediately precede the seizures are widely different in character, variability, intensity, and duration. They may occur in the mind, the sensations, the muscular system, or the general bodily condition.

The mental prodromata are of many kinds; in some cases there is a distinct idea, never spontaneously presenting itself at any other period, and one which in its character and bearing is perfectly remembered afterwards; while in others there is a vague notion, recognised to be the warning of an attack, but of such indistinct character that only the fact of having entertained it is remembered. One gentleman told me that just as an attack was coming on he always thought, "This is what I had foreseen, I knew it would come on here, I ought to have avoided it by remaining away;" and this,
although there had not been the remotest suspicion beforehand that an attack was imminent, or that the circumstances about to be entered upon would be likely to induce it. Much more common is a vague feeling of fear, which is horrible enough, but happily of only short duration.

Sensorial changes are by no means uncommon, and they are of every kind, description, and indescribability. By far the most common is a “painful feeling,” sometimes said to be “most painful,” or “horribly painful and distressing,” but which, yet, the patient says—when minutely questioned—is not “pain,” in the ordinary sense of the word. It would seem to be some condition of sensation which is intensely distressing, but which is unlike what we mean by smarting, burning, aching, &c. &c. Patients sometimes say that “it is in the head,” and yet it is “not head-ache;” that it is in the epigastrium, and yet is not “stomach-ache.” In some cases the sensation is always in either the head, the epigastrium, or lower thoracic region, the lower abdominal region, or the limbs. These are stated in the order of frequency, as they have occurred to me. In a large number of individuals, however, the sensation—which is sufficiently distinct and consistent for them to know that an attack is coming—is so vague that they cannot assert whether it is in the head, chest, abdomen, or limbs. Sometimes there are hallucinations of the special senses; one patient told me that he always heard “an infernal noise, something like that outside a booth at a country fair;” another that he had “a vision of a hideous donkey.” It would be waste of space to enumerate further these prodromata.

Premonitory symptoms may occur in the form of tremor, twitching, tonic spasm, or co-ordinated movements, such as turning round, running some distance, &c.; or they may appear as partial paralysis of one or more limbs. The latter is stated to be more common in old people.*

The term epileptic “aura” has been sometimes used, very vaguely, to describe any premonitory symptom of which the patient could give an account; but, when more strictly limited in its meaning, it has been used to express a sensation of blowing, or of something analogous thereto, which, commencing in the periphery, passed upwards to the head, the patient becoming insensible when it had reached this point. Passing over for the present the pathological interest attaching to the interpretation of the so-called aura, it may be now stated broadly that anything characteristic of Epilepsy, in the second or limited sense of the word “aura,” is rare, but that when such premonitory symptom does occur, it varies in character in different individuals; in one class there is a pain in the limbs, which “runs up them towards the head;” in another there are some twitching movements, and “the leg draws up,” or “the arm becomes contracted;” and in a third there is some vague uneasiness about the hypogastric, or epigastric regions, which “goes up through the chest.”

* Tissot, Traité de l’Épilepsie; Œuvres, tom. vii. p. 131.
One peculiarity attaching to these symptoms is the facility with which they may sometimes be removed, and the attack averted. Pain may be stopped by rubbing, or by the pressure of the hand, or of a ligature; contractions may be undone by forcible extension of the limb; and the uneasiness in the abdomen may be removed by a cordial draught.* The duration of the aura is very variable, viz. from a few seconds to several minutes; sometimes the feelings "come, and go again," for hours, being arrested many times in the manners I have mentioned, but at last, as the patients say, "slipping by," and being followed by the fit.

There are, further, premonitory symptoms in the vascular system, and in the secreting organs, such as altertations in the colour of the face, or of the fingers, a redness or duskiness of the lips, a blue colour of the gums, an excessive salivation, a change in the nature of secretions; † but these are of rare occurrence, and of such variable character that the mere fact of their existence is all that need be stated here.

The relative frequency of the different classes of premonitory symptoms, so far as I have been able to ascertain, may be represented thus:—

Mental and emotional . 11·1 per cent.
Sensational . . . . 19·8 "
Motorial . . . . 8·6 "
Vascular and Secretory . 3·7 "

Prodromata were declared, positively, to be absent in 40·7 per cent., whereas information was "doubtful" in regard of 16·0 per cent. The most common precursory sensation was vertigo; there was little difference to be observed between the relative liability of the two sexes to any one form of "warning."

Actual Symptoms of the Attack.—For the purposes of description it is desirable to divide the epileptic paroxysms into three stages.

In the first stage of the attack there are the following phenomena, which occur—not successively, as they are necessarily represented in writing, but—simultaneously, or with only slightly varying order:—

Loss of consciousness, i.e. of perception and volition.
Tonic contraction of the muscles throughout the body, with some excess of power on one side, or in one direction.
Impeded, or arrested respiration; with or without a crying noise.
Pallor, redness, or duskiness of face; either the one or the other, often the one succeeding the other in the order they are mentioned.
Dilatation of the pupils of the eyes.
Natural, weak, or imperceptible radial pulses, with throbbing carotids and distending veins.
This stage lasts from two or three to thirty or forty seconds.

* See cases recorded by Author, op. cit. p. 92.
The loss of consciousness is usually sudden and complete; the patient falls down, or is—as it were—"thrown down" in a moment, with or without warning; but even when the warning occurs, so that he may change his position, or call attention to his wants, habitually the passage from consciousness to unconsciousness is abrupt, and the loss absolute. Sensation is, at the same time, in abeyance; although some reflex acts may be excited.

The tonic spasm of the muscles is peculiar; the patient usually appears to be straining round towards one side, as if striving to look over and behind one of his shoulders. The eyeballs, the head, the arms, and the trunk, turn and twist round, so as to give the impression I have mentioned. There is universal strain, but not actual equilibrium. Every limb is rigid, every muscle is at work; but some one set of muscles in each limb proves slightly stronger than its opposing set; and the limbs pass slowly, in a stiffened manner, and sometimes with slight jerking movements, from the positions that they occupied before the attack commenced. The head, neck, and trunk share in a similar movement, and its direction is usually uniform in the individual epileptic.

Respiration is arrested, the patient appearing just like a man forcibly "holding his breath;" and in nearly half of the cases which have fallen under my own observation, the stoppage of the breathing has been so complete that no sound whatever has escaped from the mouth. In a certain number of individuals the respiration proceeds without actual interruption, but its movements are diminished in force; whereas in a very small number there is no change whatever.

In an uncertain proportion of cases there is the "epileptic cry," a peculiar and hideous sound, of which there are two distinct varieties. Some individuals utter a yell at the very commencement of the attack, and just before there is the peculiar holding of the breath I have described. Others do not "cry," but emit a groaning sound, which is, as it were, squeezed out of them by the quasi-tonic contraction of the muscles of the chest. There is, in fact, in regard of respiratory movement, a condition analogous to that observed in the limbs and trunk; viz. that of strain, but of imperfect equilibrium. As in the limbs there is a stiffened movement, from the fact that one set of muscles overcomes its opponents, so in the chest, sometimes a slow expiration, sometimes an inspiration is performed, and with either of these there may be a groaning sound. Usually there is but one sound—either a yell or a smothered groan; there is no repetition of either the one or the other.*

Pallor of the face is observed immediately before, and at the very onset of the attack in many; it is not present in all; and it occurs more certainly, and more notably, in females than in males. In other instances the face remains absolutely unchanged in regard of colour,

* I state this as the result of special attention to this point, as in a singular case, occurring many years ago, the question of the possible number of "cries" an epileptic might make assumed some importance in a medico-legal inquiry.
whereas in a larger number there is suffusion of a florid, dull red, or dusky hue.

Dilatation of the pupil occurs, and so far as I have seen, invariably, at the onset of attack. In one case, however, I witnessed a momentary contraction before dilatation commenced.

The pulse, as felt at the wrist, is usually small, and is sometimes quite imperceptible; but in several cases that I have observed there has been no change whatever in either the force or rapidity of its beats. When it has been imperceptible, there has been highly marked tonic spasm of the limbs; and often at the same time the heart may be seen, felt, and heard to be acting, and that even forcibly, and there is obvious throbbing of the carotid arteries.

In the second stage of the attack there are the following symptoms:—

Persistent unconsciousness.
Clonic convulsion.
Laborious breathing, with gurgling, foaming, and the like.
Darkness of face and body generally, with cold, and often profuse sweating.

Oscillation of the pupils.
Throbbing, laboured pulse, and palpitation of heart.

This second stage may last from a few seconds to five or ten minutes, its features gradually passing into those of the third stage. The transition from the first to the second stage is abrupt, and is determined by, what may be termed, the “letting go” of the breath which had been “held” before.

Clonic spasms are, more or less, universal; often they are more highly marked on one side of the body than on the other. The jaws are clamped together, the tongue is bitten, the limbs are thrown about, the bladder, rectum, and vesiculae seminales may be evacuated; there are rumbling noises in the intestines, hiccup, and vomiting. The eyeballs are rolled outwards, and in every direction but that which is natural, and the aspect is as hideous as can be conceived.

Respiration is violently and convulsively performed; the diaphragm may be felt through the abdominal walls; the chest heaves; the alae nasi are forcibly dilated; and the patient is in the condition of one who has made a most violent effort, and is now “out of breath.” Mucus is heard rattling in the trachea, and is often blown out of the mouth, bloody from the bitten tongue, or cheek. There is obviously great excess of secretion, and much of the distress of the sufferer appears due to his want of power to get rid of it.

Duskeness, or lividity of the surface appears to increase, and it reaches its maximum just as the clonic spasms begin to abate in their severity, and the second stage passes into the third. The sweating is often excessive, and in some cases has been observed to have a peculiarly foetid odour.

The pupils vary from contraction to dilatation, and back again, not, however, becoming so widely dilated as they were at the onset.
of the seizure; and they are, to some extent, influenced by exposure to light.

The veins are greatly distended, especially those of the throat; the heart beats tumultuously; friends of patients say, "it seems as if it would beat through the chest;" the carotids throb, and the arterial pulsation everywhere is violent, and the vessels are full.

In the third stage, there are many of the phenomena of the second, out of which it is gradually developed,—that which marks its arrival being the partial return of sensation, consciousness, and voluntary power.

The movements now witnessed are not wholly meaningless; the patient makes an attempt to change his position, or to do something; his efforts often, however, being frustrated by some violent spasm; he "looks" at those around him, with a bewildered, suspicious, or sad expression; still there is "expression;" and he may make some attempt to speak; the respiration becomes less unruly, he can clear his throat; the pupils are contracted, but he can see; the conjunctivæ are injected, and there are often petechiae on the forehead, the temples, behind the ears, and in the eyelids; the pulse is variable; there is a jaded, exhausted state, and the patient seems tired, and disposed to sleep.

This third stage may last from a few seconds to ten minutes, when the "after-stage" of stupor sets in. Often there is a confused mental condition, with occasional involuntary movements, lasting for several hours: often the patient recovers rapidly, and goes on with what he was doing before the attack occurred. There is, indeed, almost every degree of severity in the seizure; sometimes all the symptoms I have mentioned being passed through in a far shorter time than it takes to describe them; sometimes each stage being prolonged, and the patient passing gradually into a condition of stupor, from which he awakes, even after many hours, jaded and "beaten," and from which it takes several days for him to recover.

Vomiting often follows the attacks in many individuals; in some it is a constant sequence. Large quantities of pale urine are secreted in the majority of cases; both the urinary water and the amount of urea are increased; and deposits of uric acid and of urates may be discovered. I have, however, failed to find either sugar or albumen in the urine of those epileptics who were not affected by either diabetes or Bright's disease.

The after symptoms of an epileptic paroxysm vary widely in character, severity, and duration. There is usually lassitude and stupor. It is difficult to rouse the patient, and, if awaked, he is often peevish and irritable, and sometimes suspicious. The sleep is usually tranquil, but occasionally disturbed, as if by dreams. There is commonly stertor, coming and going, guttural in tone, and unlike the noise made by mucus, rattling in the trachea, during the second stage. The muscular condition is that of relaxation, occasionally interrupted, for a moment, by clonic spasm, or fibrillar contraction.
This stupor may last, if the attack has occurred in the evening, throughout the night, passing insensibly into ordinary sleep. But when the seizure has taken place in the day-time, its average duration has been one hour. It has not appeared to me to bear any constant relation to the severity of the attack as measured by the violence of convulsion. It is often absent in lunatics who are subject to epilepsy.*

(d) Epilepsia Abortiva, or Epilepsia Gravior without complete Loss of Consciousness.—It is for the sake of practical convenience, rather than because it is strictly speaking pathologically correct, that the class of cases now to be described are mentioned in this place. Names, as employed in the science of medicine, are useful modes of recognition, and not exhaustive descriptions of the maladies they denote. We must give names to the diseases we describe; we must define what we denote by the names we use; yet, in so doing, we draw besides the necessary, some artificial lines; and it is occasionally the least of many evils to overstep them.

The attacks to be described are almost excluded by our definition of Epilepsy, yet they so closely resemble that disease in all their own features, that they find a more fitting place in this portion of a System of Medicine than they could find elsewhere. They are closely related pathologically, and we find in their position here an example of the general principle of terminology employed in this work, and no departure from its spirit.

Abortive attacks of Epilepsy have been described by Dr. Prichard (Treatise on Diseases of the Nervous System, p. 91); M. Doussin Dubreuil (De l'Epilepsie en général, p. 16); Schr. van der Kolk (Pathology of the Medulla Oblongata, Syd. Soc. Transl., p. 211); Maisonneuve (Recherches et Observations sur l'Epilepsie, p. 22); Dr. Radcliffe (Epilepsy and other Convulsive Affections, p. 164); Herpin (Du Pronostic et du Traitement de l'Epilepsie, p. 429); and M. Brown-Séquard has detailed the occurrence of similar phenomena in animals (Journal de Physiologie, tom. i. p. 474). Several cases of seizures of an abortive character have fallen under my own observation; and what is to be said about them will occupy but little space. There has been sudden tonic spasm of the face, neck, and chest, accompanied by arrest of respiration, and followed by clonic convulsion, having the general form of an ordinary epileptic paroxysm; and yet there has been either no interference with consciousness, or only such slight obscuration as to be at first completely denied by the patient. Such paroxysms may occur, at intervals, for many years; they may take place in those who are subject to ordinary epileptic attacks; or they may exist in connexion with other signs of disease in the nervous centres.

The interparoxysmal symptoms of Epilepsy may be divided into

* Dr. Bucknill, Asylum Journal, for October 1855.
those pertaining to the nervous system, and those not so related. The
"nervous" phenomena exist in regard of mind, sensation, and mo-
tility, and they are of varying intensity, prevalence, and kind. The
most important are those which belong to the mental history, and
they will be considered first.

(a) Mental Condition of Epileptics.—A prevalent belief is that
some form or degree of mental deterioration is necessarily associated
with Epilepsy. The result of inquiry upon this point is to show that
there is no such "necessary" relation. The general belief is, however,
to be accounted for partly by the strong impression which some
notable cases of mental failure have made upon the minds of those
who witnessed and recorded them,—such strong impression being
followed by an undue inference,—and partly by the fact of the words
Epilepsy and epileptic having been made to include every form of
disease of brain, spinal cord, or other organs, which might be asso-
ciated with fits, and also every variety of that multiformal derang-
ment, which we call "insanity of mind." It is desirable, again, to
assert that this article refers only to such cases as constitute Epilepsy
proper; and that the statistics upon which my results are based, can
only with a double injustice be compared with those derivable from
lunatic asylums. A patient may be epileptic and a lunatic; he may
be epileptic and asthmatic; but there are some epileptics whose minds
are as healthy as their lungs; and, so far as the natural history of
Epilepsy generally is concerned, it is a mistake to derive it from
complicated cases.

The mode in which I have endeavoured to answer the question,—
what is the actual mental condition of epileptics during the intervals of
their attacks?—has been the following:—I have divided epileptics
into four classes: in the first there are placed those in whom, neither
by the patients themselves, by their friends, nor by myself, could
there be detected any deviation from mental health; such individuals
had "nothing the matter with them," but exhibited for their station
in life and educational advantages, the full average amount of intel-
lectual vigour and cultivation. The second class consists of those
who presented that slight defect of memory which is limited to the
occurrence of recent and trifling events, the memory for those long
since past being intact; and in those who formed this group, such
impairment of memory was the only departure from mental health.
In the third class are those cases which present, in addition to the
loss of memory described, some diminution of the power of appre-
hension. Such patients are dull in acquiring new ideas, and often
receive incorrect or imperfect and confused notions of what is brought
before them. The fourth class includes those who, in addition to the
failures exhibited by the preceding groups, are habitually confused,
and unable to follow out any train of thought; people who seem to
think little, but to be in a vacant, wandering state of mind, often
idle, stupid, and indifferent, and sometimes almost or completely
demented.
Having determined upon this principle of arrangement, it is comparatively easy to answer many questions of interest with regard to epileptics, and to state the answers to such questions in numerical terms. This I have done in another work; * and all that it is thought desirable to do now is to give some of these results,—and with them others based upon a wider range of facts,—without burdening the reader with a number of statistical details.

In rather more than one-third of all the cases which I have examined there has been perfect (i.e. average) mental integrity; in a little less than two-thirds, there has been some intellectual deterioration, but this has existed to a high degree in only a very small proportion. Women have been found to suffer more frequently and more severely than men; and the commonest form of failure is that of defective memory; this faculty being diminished, especially in regard to recent and trifling events.

It is of much interest to know the conditions which determine mental failure in the epileptic, and thus to avoid certain errors which are prevalent upon the subject. The results of inquiry upon this point may be stated in the following propositions:—

Hereditary taint is without influence.

The age at which Epilepsy commences exerts a certain amount of influence, and to this effect:—that the disease when appearing late in life is more commonly associated with mental failure than it is under the opposite condition; and that the chances of mental failure are less when the attacks commence before the arrival at puberty than they are when Epilepsy is developed after that epoch. Late rather than early Epilepsy is a predisponent to intellectual failure, and this whether we divide the cases at the tenth, sixteenth, or twentieth years, and whether we consider the two sexes together, or each sex separately.

The duration of Epilepsy is, per se, without influence upon the mental condition of the epileptic.

The amount of mental deterioration is not in direct proportion—but in inverse ratio—to that of muscular disturbance, as shown by the presence of tremor, or spasm, either clonic or tonic.

The state of the "general health" does not account for that of the mind; the former may be good, and the latter bad, and vice versá; and, contrary to what would be expected, such relation is more usual than the co-existence of marked failure or integrity in both directions.

The number of attacks does not determine either the degree, or the existence of intellectual change.

Frequency of recurrence of the seizures is, however, associated with mental change; but in such manner as to show that it is not the sole condition of such result, and that it is not even a necessary condition.

The severity of the convulsive paroxysm is without apparent influence, when such severity is judged of by the duration of subsequent coma. The form of the attack appears, however, to exert a considerable

* Auct. op. cit.
influence. Neither seizures of "le haut mal," nor those of "le petit mal," necessarily induce the change of which we are speaking; but the mental deterioration of epileptics is much more clearly associated with the minor than with the severer seizures.

The nature of the exciting cause, viz. its existence in the psychical or the material elements of life, appears to be without influence in the determination of mental change.

(b) Sensorial Condition of Epileptics.—Headache and vertigo are the two forms of disturbance the most frequently complained of by epileptics. They exist, however, to a high degree, in only a small number of the cases; and when they do exist have no special character, which renders them of value in either diagnosis or prognosis. The vertigo of epileptics is commonly of such kind that the patient rarely imagines that surrounding objects are in motion, but rather that he is, himself, turning round; he feels as if he were doing so, and is unsteady in standing, or in his attempts to walk.

The pupils are more commonly below than below the average size; the special senses exhibit neither constant, prevalent, nor characteristic change.

(c) Condition of the Motorial System in Epileptics.—Some patients exhibit a tremulous state of the muscles; some, either with or without tremor, are affected by clonic spasm; others present tonic spasm, or cramp; whereas many are quite free from either of these forms of altered motility. In the majority of cases there is some kind of disturbance; but in the greater number of this majority the amount of such disturbance is slight.

The patient often says that he is "nervous," meaning by this that his hand is unsteady, or that the body is tremulous, or that he feels as if they were so.

It is often denied that any jerking of the muscles ever occurs; but the physician may frequently discover that such denial is incorrect. The amount of clonic spasm may be, therefore, very slight: it may, on the other hand, be very considerable, assuming one or both of two general forms. There may be, more or less constant and considerable, choreiform movement; and this may be observed not only when the patient is awake, but when he is asleep, and often with exaggerated force in the latter condition. There may be violent spasmodic shakings of the limbs, or of the trunk; occurring at irregular intervals, but exhibiting an especial frequency of occurrence just as the patient falls asleep. Such jactitations have proved excessively annoying in several cases, and have been so troublesome as to entail much ulterior distress from the loss of sleep that they have occasioned. Sometimes the jerk of muscles is so sudden and so violent that the patient is thrown out of bed; or, if standing, is thrown down.

Cramp, or tonic contraction, is comparatively rare, and has apparently only an accidental relation to the disease.

(d) Condition of the General Health.—There are no changes in the "general health" of epileptics to be observed with such sufficient
frequency or speciality that they deserve to be reckoned among the characteristic features of the disease. Epilepsy may exist in every condition of the general health; but among those who have been primarily poor, or who have become so, owing to their disease, a low state of vitality is encountered. A similarly depraved condition may be found where the circumstances have been different; but such state is, by no means, necessarily present. Epileptics may be found in robust, as well as in feeble health; but it is important to know the relative frequency of the one and of the other condition.

Patients have been examined by myself in regard to their nutrition, temperature, and strength, and the general results of such inquiry are those stated above. But, further, cases have been divided into four groups, viz.: into 1st, those exhibiting, in every particular, good health; the limbs being well nourished, of normal temperature, and of natural strength;—individuals capable of enduring both exposure and fatigue as well as any others of their age, sex, and social condition. 2d, those in whom some failure in one of the above particulars was noted. 3d, those in whom a double deterioration was observed; and 4th, those in whom there was deficiency in all three particulars. The result of such inquiry has been to show that more than one-half of the cases belonged to the first group; less than one-third to the second; less than one-tenth to the third; and little more than one-hundredth to the fourth. The most frequent change has been defective temperature, the least frequent impaired nutrition. The pulse has exhibited no special feature, either in frequency, force, or fulness.

There is, according to my experience, an entire absence of any specific change in epileptics, so far as regards their functions of digestion, respiration, circulation, and secretion.

If, as the result of this mode of inquiry, we regard epileptics as a whole, and put together all the results that have been obtained, we come to this important conclusion, that in a certain number (12 per cent.) there is nothing, absolutely nothing, abnormal to be discovered during the intervals of attack; that in nearly two-thirds of the cases some failure may be observed either in mind, motility, or general health; and that in less than one-third there is marked alteration.

It is then obvious that Epilepsy is a disease characterised only by its paroxysmal symptoms, and having, in the present state of science, no special features by which it may be recognised during the intervals of attack.

4. Relations between the Symptoms of Epilepsy.—(a) Forms of Attack.—The severer seizure, Epilepsia gravior, is nearly twice as common as the milder, Epilepsia mitior; and the former is much more frequently found by itself than is the latter. Hereditary taint seems to exert an influence in predisposing to the severer form of attack. The milder attacks, however, do not appear to take the place of the more severe, but to be found with especial frequency in those cases which exhibit a rapid recurrence of the latter, i.e. of Epilepsia gravior.
The form of attack does not appear to be determined solely, or even notably, by the age at which the disease commences; but when Epilepsy is developed early in life, there is an increased proclivity to the attack in its milder form. Duration of the malady does not determine its form of seizure.

(b) Frequency of Attacks.—In about one-seventh of the cases that I have examined, the seizures have exhibited a mode of recurrence which has been termed “serial;” that is to say, that the patients suffer from two, three, or more attacks in one day, and then pass through a period of freedom lasting from one to several weeks; and this mode of recurrence is more frequent in the female than in the male sex. The series, groups, or—as they are often termed—“bouts” of the fits, usually occupy one day only, and they are often limited to a period of twelve hours.

It is rare, very rare, to find an accurate periodicity in Epilepsy; but it is exceedingly common to observe that the recurrence of attacks has some kind of relation to time, as marked by its natural division into days, and periods of seven days, or multiples of seven days. Thus a large number of epileptics have their seizures every day, every two weeks, three weeks, and four weeks; while only a much smaller number suffer at such irregular intervals as cannot be thus expressed. An almost identical number of patients state that they have attacks at each of the periods mentioned; not meaning by that to say that there was always either perfect periodicity, or recurrence “to the day,” but that, as a rule, every fortnight, three weeks, month, or day, there had been an attack.

There are four times as many epileptics who suffer from their seizures more frequently than once a month than there are of those whose attacks recur at longer intervals. The return of attacks at monthly periods is rather more common in the male sex than in the female; and it is very rare to find the seizures limited to the time of the menstrual discharge. It is frequently noticed that they are more common during menstruation; but, on the other hand, many women whose attacks recur at monthly intervals exhibit no marked proclivity to their recurrence while the catamenia are present. A high rate of frequency is more common among women than among men.

The number of attacks in a given time ranges between very wide limits—from two to two thousand in a year; but half the cases are found to have a rate of recurrence ranging from one attack in fourteen to one in thirty days.

Great frequency of attack is not constantly associated with signs of motor disturbance, such as tremor, clonic spasm, and the like.

Again a high rate of frequency is not determined by an enfeebled state of the bodily health; but, on the contrary, is observed in those whose general physical condition is up to the standard of health, whereas a low rate of frequency is found in those whose organic powers have undergone marked deterioration.

An early commencement of Epilepsy is commonly, but not neces-
A SYSTEM OF MEDICINE.

sarily, associated with a high rate of frequency in the attacks. As the disease continues it exhibits a tendency to increase in the frequency of its paroxysms; but duration is not the sole condition determining this result.

(c) **Morbid Motorial Phenomena** are not found exclusively in those who exhibit an impaired state of the general health, but the one kind of derangement—marked by tremor, or clonic spasm—is commonly found in combination with the other, viz. diminution of temperature, or nutrition, or strength.

The prolongation of Epilepsy is not necessarily associated with impairment of the physical condition; but a high degree of the latter is often found in conjunction with a protracted duration of the disease.

(d) **Consequences of Epilepsy.**—If Epilepsy were found to entail, of necessity, any definite changes in the health of its subject, in regard of either mind, motility, or general condition, we should expect to find that such changes bore a definite and direct relation to the time during which the disease had existed. On this point, however, the result of a careful examination leads to the conclusion that duration is, *per se*, without effect, and that the demonstrable "consequences" are nil.*

5. **Complications of Epilepsy.**—These may exist in any organ of the body, but they have no such definite character except when they are presented by the nervous system as to require any special comment in this place. The most important is:—

**Epileptic Mania.**—This complication occurs in about one-tenth of the cases, if we reckon all those degrees of such disturbance as may warrant the application of such name. Having occurred once in a particular individual, it is likely to appear again, and this is especially the case when several attacks have followed in rapid succession.

The delirium is commonly but not universally furious and dangerous; it is sometimes ecstatic in form, sometimes dull and melancholic. It may appear in the form of preternatural gaiety before the attacks, or in the intervals of their recurrence; it may break out as violent excitement just as the patient is emerging from the second stage of the paroxysm. Sometimes the mania has preceded the convulsions, but this order of events is, comparatively speaking, rare. Epileptics occasionally have some premonition of their maniacal state;—an indescribable feeling which leads them to place themselves under restraint before the occurrence of the outbreak. More commonly, however, there is no such warning, and the physician fails to discover any special reason for the attack.

**Meningitis** in an acute, sthenic form, may follow epileptic paroxysms; but when it has done so, it has, in the majority of cases, been determined by some accidental injury inflicted by a blow or fall, which the patient has experienced in one of his attacks.

**Apoplexy** is so rare a sequence of Epilepsy that it is mentioned simply for the purpose of stating this fact, because it—apoplexy—is

* *Auct. op. cit. p. 199, et seq.*
one of the dangers often quite unnecessarily dreaded by both epileptics and their friends.

*Idiotcy* may be complicated by Epilepsy; but when the two conditions are found together, or are stated to co-exist, the truth appears to be this, that the idiotcy has been congenital, and that the idiot has been “subject to fits.” Abundant facts and reasons have been already furnished for the purpose of proving that the mode of regarding Epilepsy proper which would show that idiotcy is one of its frequent complications is fallacious, inasmuch as it widens the meaning of the word Epilepsy beyond what is pathologically correct, or practically desirable.

*Convulsions,* such as those attending upon dentition or parturition, exhibit no special frequency of occurrence in epileptics.

*Paralysis* is so rare an event that it may be regarded as having—like meningitis—an accidental, rather than essential, relationship to the disease in question.

*Cyanosis* is often accompanied by fits, and these have sometimes assumed an epileptic character; but cyanosis is so rare a malady that its mere mention is sufficient.

**Pathology.**—Anatomical investigation has hitherto failed to give any explanation of Epilepsy; every kind of lesion has been discovered in every organ of the body; and, on the other hand, every organ and part of organ has been found in perfect health. The observations of Wenzel,* those of MM. Bouchet and Cazauvielh, † and the later researches of Dr. Schroeder Van der Kolk ‡ have shown the existence of disease in the pituitary body, in the white substance of the brain, and in the medulla oblongata; but the changes that each of these authors has described have been found to be inconstant, and some of them quite exceptional. We must, therefore, admit the disease to be what is termed “functional,” using that word in the sense strictly defined in the first volume of this work.§ It is believed that “nutrition” is changed, but that its alterations are too fine for detection by our present modes of examination.

Bearing in mind all the facts of Epilepsy, and proceeding to their interpretation by the aid of physiology, we arrive at the following conclusions:|| —

1st. That the seat of primary derangement is the medulla oblongata, and upper portion of the spinal cord.

2d. That the derangement consists in an increased and perverted readiness of action in these organs; the result of such action being the induction of “spasm” in the contractile fibres of the vessels supplying

|| The reader is referred to the Author’s Treatise on Epilepsy, chapter Pathology, for a full exposition of the views here stated propositionally, and also for complete reference to the different authorities quoted in support of each proposition.
the brain, and in those of the muscles of the face, pharynx, larynx, respiratory apparatus, and limbs generally.

By contraction of the vessels, the brain is deprived of blood, and consciousness is arrested; the face is, or may be, deprived of blood, and there is pallor; by contraction of the muscles which have been mentioned, there is arrest of respiration, the chest walls are fixed, and the other phenomena of the first stage of the attack are brought about.

3d. That the arrest of breathing leads to the special convulsions of asphyxia, and that the amount of these is in direct proportion to the perfection, and continuance of the asphyxia.

4th. That the subsequent phenomena are those of poisoned blood; i.e. of blood poisoned by the retention of carbonic acid, and altered by the absence of a due amount of oxygen.

5th. That the primary nutrition-change which is the starting-point of Epilepsy may exist alone, and Epilepsy be an idiopathic disease, i.e. \( \text{a morbus per se.} \)

6th. That this change may be transmitted hereditarily.

7th. That it may be induced by conditions acting upon the nervous centres directly, such as mechanical injuries, overwork, insolation, emotional disturbances, excessive venery, &c.

8th. That the nutrition-change of Epilepsy may be a part of some general metamorphosis, such as that present in the several cachexiae, rheumatism, gout, syphilis, scrofula, and the like.

9th. That it may be induced by some unknown circumstances determining a relative excess of change in the medulla, during the general excess and perversion of organic change occurring at the periods of puberty, of pregnancy, and of dentition.

10th. That it may be due to diseased action extending from contiguous portions of the nervous centres, or their appendages.

11th. That the so-called epileptic aura is a condition of sensation or of motion dependent upon some change in the central nervous system; and is, like the paroxysm, a peripheral expression of the disease, and not its cause.

**Diagnosis.**—Bearing in mind all the features of this disease as they have been described and limited in the foregoing pages, it will be comparatively easy to distinguish Epilepsy from every other malady.

The disease may be *simulated*, and when such is the case the fraud may be detected by the "over-acting" of the pretender, and longer duration of the paroxysm; by the choice of locality for the purposes of display; by the absence of those changes in colour which have been described; and last, but most certainly, by the absence of dilatation of the pupil.

*Syneopal Attacks* often resemble closely those of "le petit mal;" and the latter may be mistaken for the former. There is, perhaps, a much closer analogy between them than is sometimes supposed. For practical purposes of prognosis and of treatment, the distinction will
turn upon these points of difference; in Epilepsy loss of consciousness is sudden, absolute, and often without any sense of "faintness;" recovery is rapid, and there is no recollection of the attack.

Hysteria, when convulsive in form, differs in the presence of some volition, some sensation, some power of directing movements. The attack is "got up," or passed into, gradually; and is preceded by sobbing, crying, laughing, and gesticulations: it continues sometimes for an indefinite period, and passes off through a stage of hysterical excitement.* The history of the case before the attack, and after its occurrence, is that of hysteria; whereas in Epilepsy there is or may be nothing abnormal to be discovered. In the attack there is not the hideous distortion of the features, neither is there the meaningless eye, nor the dilated pupil; nor the bitten tongue; respiration may be, and generally is disorderly, but there is no marked asphyxia. After the attacks the patient is exhausted, but does not pass into stupor; hysterical mania or paralysis may follow, but they have their own special features.

Convulsions—such as those of teething, of worms, and the like—differ as widely from Epilepsy as attacks of bronchial catarrh do from genuine spasmodic asthma. The presence of dyspncea, cough, and expectoration does not constitute a case of asthma; the loss of consciousness and convulsion does not constitute a case of Epilepsy. The real nature of the disease must be determined by those facts of its history which lie behind these symptoms, and determine its position in nosology. Convulsions may occur many times, and may sometimes pass into the disease we are describing; but they do not necessarily do this, and mere periodicity of recurrence is not the only mark between them.

Convulsions are most frequently found during infancy, and especially so while the child is cutting its first set of teeth. It is rare for Epilepsy to date from so early a period. Usually febrile symptoms precede the attack, or there is some definite source of irritation in the mucous membrane or secreting organs—e.g. dentition, worms, indigestion, scybalæ, calculi. The first occurrence of the convulsion and its subsequent repetition may be traced to one or more of the irritations enumerated. The attacks cease on the removal of their "exciting cause;" and they differ from Epilepsy in the following features:—their invasion is less sudden, and the paroxysm is of shorter duration; there is not absolute loss of consciousness at the onset of attack; if perception, volition, and sensibility are entirely removed, such removal is during the clonic spasm, and not at the beginning; there is little or no subsequent stupor, and no paralysis.

The diagnosis of diathetic convulsions is based upon a recognition of the diathesis. At the onset of some of the exanthemata convulsions may occur, and assume an epileptic form, but they are to be distinguished by the fact of their appearance in early life, the patient being usually under six years of age; by the presence of febrile dis-

* See article on Hysteria.
turbance, and of some exanthem, or some acute inflammatory change such as pneumonia, or bronchitis.

In "Bright's disease" of the kidney convulsions of epileptoid type may be the first symptoms which bring the patient under the notice of the physician. There will, however, be but little difficulty in establishing the diagnosis. There are marked and peculiar pallor, puffiness of eyelids or of ankles, and albuminuria. The attacks are followed, or have been preceded, by drowsiness, listlessness, and a tendency to delirium; there are headache, vertigo, clonic spasm, alternating with marked rigidity of limb, great irritability of the muscles on percussion, and often a highly characteristic state of the mental functions. The latter has these features: the patient lies in apparently profound coma, with some limbs relaxed, and others rigid or in clonic contraction, breathing heavily with a stertorous sound, which may be found to exist in the mouth, and not in the throat; but, from this state of apparently profound stupor, he may be readily aroused to do that which he is told to do, or to answer questions; and immediately afterwards he falls again into the state of stupor. His condition resembles somewhat that of a person poisoned with opium.

It is sufficient to mention such diseases as chronic alcoholism, lead-poisoning, syphilis, and rickets, in order to indicate the means by which, when they are attended by convulsions, the diagnosis may be established. Organic Diseases of the Nervous Centres may be distinguished from Epilepsy by the fact of their presenting symptoms over and above those proper to the latter. When conspicuous and persistent changes in the functions of the nervous system occur during the interparoxysmal period, we may infer the existence of structural disease. Again, there is more marked impairment of the general health; and the signs of disordered nerve-function have a more rapid development than have those which may occasionally be observed in Epilepsy. Tumour of the brain exhibits its most characteristic feature in persistent, or paroxysmally exaggerated pain, limited to a particular locality, and accompanied by local paralyses. Chronic softening may be diagnosticated by the gradual failure of mind, sensibility, and muscular power. Chronic meningitis may have a protracted history, but it is one of highly marked interparoxysmal change. There is irritability of temper, and, occasionally, delirium with loss of memory and impaired intellectual power: there is spasm alternating with local paralysis; and there are alterations of the special senses, with headache and general malaise.

The convulsions which occur in chronic cerebral diseases are not precisely like those of Epilepsy; there is less suddenness in their invasion, there is not the complete loss of consciousness, the convulsive movements do not pass through the several stages that have been described, but are irregular in their manner of development, protracted in their duration, and often limited to one side, or to one extremity. There are not the asphyxial phenomena of Epilepsy, neither is there the subsequent stupor.
Again, the ages at which intra-cranial diseases are developed differ from the prevailing age at which Epilepsy makes its appearance; neither aneurism nor carcinoma appear, as a rule, so early in life as does the disease under consideration; cerebral tubercle, when occurring in childhood, has a history widely different from that of Epilepsy; and, lastly, each of these is attended by its own special dyscrasia, which may afford all that is needed to complete a diagnosis.

Prognosis.—When the disease has been established for some time, and is recognised to be an idiopathic affection, the prognosis is unfortunately very unfavourable as regards perfect and permanent cure. When it is recent, much hope may be entertained. Cases of eccentric convulsions, and of chronic meningitis, either syphilitic or simple, may be cured, and such are often spoken of as epileptic; but I do not include them in the present article: the remarks here made apply exclusively to Epilepsy proper.

The general prognosis is framed upon several different considerations. Hereditary taint is of unfavourable omen; whereas an early commencement of the disease is the reverse. The duration of the malady is of the highest importance; the longer that it has lasted the greater is the difficulty and improbability of cure. Those cases in which the intervals between the attacks are much prolonged are less amenable to treatment than are those which exhibit a more rapid recurrence. Mental failure is of evil augury, but not to so high a degree as has been supposed. Some of the most obstinate cases are those in which the general health is good; some of the most tractable are those in which there is a disturbance which may be corrected.

Next in importance to that of the prognosis of the disease as a whole, is the forecasting of the mental state, supposing that the disease itself cannot be cured. What conditions are there which would render mental failure probable? The chapter on "natural history" supplies the answer to this query, but its results may be recapitulated here. Hereditary taint is without influence; the female sex is of unfavourable omen; late commencement of the disease is a predisponent to intellectual failure; mere duration is without influence; an impaired state of the general health is of good rather than evil import; mere number of attacks is of no moment; rapid recurrence of seizures is indicative of danger; and attacks of "le petit mal" are more injurious than are the severer paroxysms.

The danger to life is somewhat remote, and need scarcely be entertained. It is excessively rare for an epileptic to be killed by, or die in one of his attacks. Van der Kolk * has shown that the danger to life is greater in those cases in which the tongue is not bitten; but I have no observations to prove either the correctness or the incorrectness of this opinion, as I have never yet known a case in which the attack proved fatal.

TREATMENT.—There are two distinct elements to be regarded in the therapeutics of Epilepsy: the one is the diminution or removal of the condition which is the essential element in the disease; and the other is the mitigation of the paroxysmal symptoms when their removal cannot be effected. We have to direct the treatment of the disease, and that of the attack.

It has been already stated that many epileptics, during the intervals of their paroxysms, present no abnormal condition; yet it is to be inferred that there must exist in them some departure from health, and the conclusion to which we have arrived is, that this departure consists in an undue readiness of action of certain portions of the nervous centres. Our object, therefore, is to control this over-readiness of action. For this purpose sedatives have been employed, and with success. It would be useless to attempt any estimate of the relative value of many of these agents, for there are no data sufficient for the purpose. Opium or morphia, conium, hyoscyamus, stramonium, belladonna, cannabis Indica, atropine, valerianate of atropine, selenium palustre, cotyledon umbilicus, chloroform, and other medicines have been employed with good effect in some cases, and without any appreciable effect in others, and hitherto no principle has been evolved from either their failure or success. When the attacks have been of very frequent recurrence, I have found preparations of the solanaceae useful in diminishing the number of seizures, but I have never known them to effect a cure. Opium, or some preparation of morphia, has been of service when the patient was restless at night, and was obviously suffering from the effects of loss of rest. Chloroform has delayed attacks while the patient was actually under its influence, but has failed to prevent their subsequent recurrence. Dr. Murray has, however, been fortunate in the treatment of some cases by means of chloroform, and his observations are such as to warrant a further employment of this agent.* Indian hemp has relieved headache and restlessness, but has not cured or notably relieved Epilepsy.

The salts of zinc, and especially the oxide of zinc, have appeared to be of service in many cases; their action being obviously that of a sedative. I have seen no good results from sulphate of zinc given in heroic doses, and the good effects that have come under my own observation have been from oxide of zinc in doses of three or five grains given three times daily. The salts of copper and of silver have proved utterly useless in my own experience.

Bromide of potassium is the one medicine which has, so far as I know, proved of real service in the treatment of Epilepsy. Undoubtedly it is "sedative" in its action; it lessens spasmodic movements of almost every kind, and sometimes ensures sleep when vegetable sedatives, and among them, opium, have failed. Bromide of potassium in small doses has appeared to be of little or no service, but in large doses it has scarcely ever failed to give much relief. Sir Charles Locock has the merit of introducing this drug to the notice of

* Medical Times and Gazette, April 8, 1865.
the profession in this country,* and the testimony of all those who have had much experience in the matter concurs to a remarkable degree as to its utility. Given in doses, ranging from ten to thirty grains, three times daily, it has had these effects:—in some cases it has completely cured the patient, and the cure has been permanent for years, and is so now. In others it has arrested the attacks so that none have occurred for periods varying from a few months to two or three years; but, on the omission of the medicine, the seizures have returned. In such cases the attacks have again ceased on the re-administration of the medicine. In a third series of cases it has diminished the frequency and severity of the seizures, but has not removed them altogether; the patients while taking the bromide have had one-half or one-third of the number to which they were habituated. Such patients have gone back to the old frequency of recurrence when the drug has been omitted, and have again improved when it has been re-administered. In a fourth, but very much smaller number, the influence of the drug has been good for a time, and has then appeared to cease; and in a fifth, and yet smaller proportion, it has been apparently without any appreciable effect. Dr. Duckworth Williams has shown that it exerts much influence over those cases in which the attacks take place during the day, but that it is of little use in those patients whose seizures occur during the night.† I have found that this is true to a certain extent, but not to the degree described by Dr. Williams; for in several instances KBr. has been very useful when the fits were limited to the hours of sleep. It is possible that Dr. Williams’s cases may have been, from the fact of their complication with insanity, peculiar in this respect.

It is to be demonstrated, in my opinion, that there is something “specific” in the action of KBr. Potassium—given as an iodide—is without such effect; and bromine—given as bromide of ammonium—has no obvious influence upon Epilepsy; but, in combination, these two “elements”—bromine and potassium—are of undoubted value.

In an earlier part of this article (p. 258) I have given reasons for thinking that the mode in which KBr. proves useful in Epilepsy is not by its diminishing either the sexual propensity, or power. It is positively curative of Epilepsy when given in doses which exert no influence whatever upon the generative functions.

Having hitherto given KBr. to many hundreds of individuals, I have witnessed no ill effects from its administration. I say advisedly no ill effects, for in only three cases have there occurred any unpleasant symptoms which could, by any possibility, be referred to the drug; and these symptoms were different in each of the three. In one patient, after sixteen months’ administration, there was some swelling of the nose, and of the submaxillary glands, which annoyed the patient, but subsided on the discontinuance of the drug; in another there was an irritable vesicular eruption on the skin, which disappeared directly

the medicine was omitted;* in a third there was the recurrence of syncopal sensations, which subsided on the addition of twenty drops of chloric ether to each dose of the bromide.

These discomforts are so rare that they may be regarded as, most probably, accidental. Dr. Williams‡ states some facts which would appear to prove that KBr. does diminish the force of the heart’s action; but in my own experience this has not occurred, to any such degree, or with such frequency, as to make me attach any importance to its occurrence. Bromide of potassium has arrested Epilepsy without producing any diminution of cardiac action; and in all cases where there has been the least suspicion of such effect, the addition of chloric ether, or of tincture of cinchona, or indeed of any diffusable stimulant, has at once removed the threatened inconvenience.

Counter-irritation, and derivants, such as setons, issues, and the like, have appeared to me to be of signally little service in genuine Epilepsy, so that I have been led to the belief that those cases in which they have been said to be of great utility have been examples either of some other malady, or of some complication of the disease.

As to diet and regimen, these things seem to me important: first that the patient should eat digestible meals, with great regularity; and second that exercise, in the open air, should be taken as much as possible, short of fatigue. Many epileptics have been relieved from nocturnal attacks by being made to sleep with the head and shoulders well raised, not by pillows, but by a simple contrivance which is placed under the upper half of the bed or mattress on which they lay. Baths used for the purposes of cleanliness are useful in Epilepsy as in many other diseases; but I have seen more harm than good follow the employment of douche, shower, and sitz baths, when these have been administered in any manner or to any degree which exceeds that of producing comfort to the individual. Warmth to the extremities, especially at night, is of great value; the patient should never go to bed with cold feet, nor run the risk of their becoming cold during the night. Fires, hot water, hot-water baths, and woollen socks, may prevent much mischief. Sexual intercourse appears to me also to be one of those matters upon which the dictates of common sense are sufficient without any special direction from the physician.

The mental state of the epileptic may be much injured by action upon one very common form of advice, viz. that the patient should “do nothing.” It is desirable to avoid over-exertion, worry, and undue excitement; but wholesome mental exercise is of great utility; and some definite employment, carried to a point short of fatigue, should be enjoined as part of the treatment of those cases which are not complicated with cerebral excitement.

It is impossible to pay too great an amount of attention to the “general health” of epileptics, but there is nothing special in regard

* Since the above was written, it has occurred to me to meet with a similar eruption in several women who were taking the medicine.

to this matter. Cod-liver oil, quinine, iron, alteratives, and aperients must be given in circumstances when their exhibition would be desirable in other forms of disease.

Allusion has already been made (see p. 259) to the operation of clitoridectomy, and reasons have been given for suspending judgment on the matter. Doubtless success has followed such treatment in some cases, but the results are, at present, too uncertain for the formation of a definite opinion, first as to the stability of the cure; secondly as to the class of case in which the operation is justifiable; and thirdly as to the therapeutic modus operandi of clitoridectomy when it has appeared to be useful. It is not only possible, but highly probable, that an operation of severity equal to that of clitoridectomy might prove serviceable in some cases of Epilepsy if it were performed on the back of the neck, the mouth, or the toes. A strong impression upon the mind, or a violent change in the body, such as the opening of an issue, the performance of tracheotomy, or the occurrence of an accidental burn, has often arrested the attacks. It is probable that clitoridectomy and circumcision may, in some cases, act beneficially in a similar manner; but it is obvious that, if they do, the form and locality of operation might be changed with advantage. So far as my own observation extends, the cases are almost infinitely rare in which such an operation would appear to me to be allowable.

The application of ice to the spine has, of late, been advocated with great ability by Dr. John Chapman; and there appear to be many theoretical considerations warranting the employment of this mode of treatment. It is not my purpose to detail the theory upon which Dr. Chapman has acted, as it is fully explained in his own writings. I regret to say that such application has utterly failed to do any good in a very large number of epileptics for whom I have prescribed it. Ice has been applied in the manner recommended by Dr. Chapman, and has been persevered in for many months, without producing the smallest effect upon the frequency or severity of the paroxysms. In one case, at University College Hospital, it was applied, both night and morning, without influencing the disease, and on more than one occasion the fits took place while the ice-bag was on the spine. In one instance it was followed by a cure, but in this case the patient was taking at the same time bromide of potassium. For the purpose of testing its utility I have employed it in a number of cases without giving any medicine whatever, and the result has been absolutely negative; it has done no harm, but it has done no good. It has appeared in several individuals to be of service in the first instance, but soon, in spite of its persevering application, the attacks have recurred with their usual frequency and severity. Patients have not complained of its application, but I have failed to find that it exerted any influence upon their temperature, when this was tested by their own sensations, or by the thermometer applied to either the axillae or the extremities.

The treatment of the attack is mainly of value when directed towards
its prevention; and there are several means by which some good may be accomplished. When an "aura" is present, the paroxysms may sometimes be arrested by cauterising the surface from which the aura comes, or by applying pressure between the starting point of the aura and the trunk. Sometimes the attack begins by a special form of contraction in particular muscles, and its progress may be arrested by forcible extension of these muscles. Chloroform, or ammonia, if inhaled, will often prevent the seizures just at the moment of their onset; and in like manner a draught of wine, of sal-volatile and water, or of some other diffusible stimulant, will put off the attack. When patients have warning sensations, of sufficient duration for them to do anything, it is desirable that they should carry with them some little draught of this kind, which they may take at the moment of threatening. By such means a large number of fits may be averted.

Tracheotomy has been shown to be of no such real service in Epilepsy as to warrant its recommendation.

When the attack is once established, there is little that can be done beyond that of preventing the patient from injuring himself. A piece of India-rubber may save the tongue from being bitten; a loose cravat may diminish the petechial discoloration of the face; and a strong arm may hinder the bruising of the extremities.

When the paroxysm is over the patient should be allowed to sleep, and should be placed with the head and shoulders raised.

In some epileptics the mental symptoms are the most highly marked features of the interparoxysmal period, and to these attention must be mainly directed. In others the general health is greatly at fault, and in them the treatment must be turned towards its improvement. In a third class there is excessive motility of involuntary kind, and in such cases the vegetable sedatives are of marked utility; but in all, the medicine which has proved most useful, in my own experience, is the bromide of potassium.
WRITERS' CRAMP.

BY J. RUSSELL REYNOLDS, M.D. F.R.C.P.

DEFINITION.—A chronic disease, characterised by the occurrence of spasm when the attempt is made to execute a special and complicated movement, the result of previous education; such spasm not following muscular actions of the affected part when the special movement is not required.

The term "Writers' Cramp" is bad in one respect, because the symptoms it denotes do not belong exclusively to the act of writing; it is good, and therefore retained in this "System of Medicine," because it points to the most frequent form in which the disease is exhibited, and because it has already passed into general usage.

A disease pathologically similar to Writers' Cramp may be found in the artist, and may prevent him from painting in oils; it may occur in the violinist or the pianist, and hinder the musical performances of either; it may be met with in the seamstress, or the smith, or the milkmaid, and may limit or destroy their powers of work. Wherever it is found it shows the same general feature, expressed in the definition, viz. a limitation by spasm of a particular kind of movement, and of that movement only.

SYNONYMS.—Scriveners' Palsy; Mogigraphie; Schreibekrampf; Crampe des Ecrivains; Schusterkrampf; Melkerkrampf.

SYMPTOMS.—A slowly-developed difficulty in executing a particular movement, such as that of writing, or playing on a musical instrument, other movements of the same limb being perfectly easy of performance. Usually the patient feels at first some undue weariness after long exertion, a stiffness of the fingers, or an unsteadiness and uncertainty of movement, all of which immediately disappear on giving up the exertion. If writing, a man feels that his pen does not do what he intended that it should; that his handwriting looks unnatural; that he has to hold his pen more tightly than before, in order to keep it between his thumb and fingers; that it starts from its place, and often is pushed, by his first finger, over the nail of his thumb, and that he has some difficulty in getting it back to its place. A pianist makes blunders in striking chords, the fingers falling on keys they were intended to avoid: the violinist cannot control the
movements of his left hand,—or can do so only by a painful effort,—the fingers running together and feeling stiff: the seamstress cannot ply her needle, but pricks her fingers, and makes her stitching irregular. In one case, under my own care, the bricklayer could not use his trowel.

At first the difficulty is slight, and may be overcome by strenuous effort; but, after a little time, if the attempt to continue or repeat the movement be persisted in, there is distinct cramp, jactitation, or tremor of the hand, and the particular performance is quite impossible. Other things may be done, but that one thing with regard to which the difficulty was first felt cannot be effected properly by any amount of exertion.

The accompanying woodcut represents four different attempts made by one of my patients to write his name—

The moment that the attempt is given up the patient feels nothing abnormal; but the moment that he tries again to perform this special act the difficulty returns, and increases.

The cramp-movements, at first limited to the thumb and fingers, are sometimes avoided by the writer who adopts mechanical devices which leave them at rest, but make it possible to perform the act of writing by using only the muscles of the wrist and fore-arm; as soon,
however, as he has trained himself to write in this awkward manner, the muscles of the fore-arm take on a spasmodic movement, and he is no better off than before. In one case, which I have recently seen, the patient could manage to write a few words by moving only the muscles of his arm and trunk—his pen was directed by the muscles of his back and arm, the latter being pressed closely against his side; but, after a few seconds, spasm occurred in these, the whole body was contracted, the head being drawn downwards to the right shoulder, and the trunk contorted so as to render it concave on the right side.

In several cases that I have known the sufferers have taught themselves to write with their left hands, to do this with ease, rapidity, and neatness; but, shortly after having acquired the art, the left hand has become affected in a similar manner, and its writing-power has been limited more rapidly than was that of the other limb.

When the disease has existed for some time, the attempt to write often becomes painful; there is a feeling of "cramp," and much general distress, accompanied by spasmodic movements in the neck, and sometimes in the limbs not especially engaged in the effort; and yet, apart from the attempt to write, there are no spasm and no inconvenience.

After long persistence of the cramp there is sometimes feebleness in the general movements of the limb,—the grasp is not so firm as it used to be; but such quasi-paralysis is the exception, and not the rule.

In some cases the spasmodic movements have not been so closely limited, as they are in the majority, to the attempted performance of a special act. There has been tremor, or choreiform agitation of the limb, more or less persistent during the day, even when no voluntary effort is being made, but ceasing at night, during sleep, or after prolonged rest in one position.

There are—in some individuals, but not in all—abnormal sensations in the affected limb; and these may be noticed before any cramp appears. They may be increased by exertion, but do not entirely depend upon it. They are vague in character, such as a "feeling of weight," or of "tightness," "numbness," or "coldness;" a pain, but more often a "something not quite pain going up from the hand to the back." In some cases there has been actual anaesthesia of the fingers, and an "aching in the spine."* There is nothing peculiar to the disease now mentioned in the sensations that I have heard described when description was possible, except this, that the attempt to control the spasm augmented the distressing or uneasy feelings.

In the majority of cases the special cramp exists by itself; but in a few it is associated with other disturbances of the nervous system. Those which I have met with have been torticollis, occasional strabismus, stammering, and palpitation of the heart, with some distress about the cardiac region, over and above the mere fact of increased force, or frequency of beat.

* Solly, On Scrivener's Palsy; Lancet, Jan. 28, 1865.
The general health in some of the most typical cases has been excellent, and the physical strength equal to, and even beyond the average. In a few individuals there have been weakness, a "nervous temperament," and some anæmia with impaired digestion and nutrition; but in no one has there been witnessed any modification which is not consistent with, and frequently encountered in, other diseases.

Etiology.—Age. Early life appears to be exempt; I have not met with a single case in which the symptoms appeared before the age of thirty. Sex. The male sex is much more liable to suffer than the female. Occupation. It is commonly held that the disease is caused by excessive exertion, but there are reasons for doubting the correctness of this statement. Thousands of individuals write, work, milk, or play musical instruments to the highest degree that is possible without suffering from the least inconvenience of the kind now described; and, on the other hand, many cases occur in which there has been no excessive strain upon the muscles in the performance of these special acts; and, indeed, in one most characteristic example of the malady, there had been less than the usual amount of writing performed by gentlemen of the age and profession of my patient. It may then be convenient, but it is not scientific, to refer this form of cramp to over-exertion of a special kind.

Worry of mind and anxiety have been present in many cases before the outbreak of the symptoms, but so they have been in many other forms of nervous disturbance quite different from this; and in some persons affected with Writers' Cramp there has been nothing of the kind to which the patient or others could refer the symptoms.

Diagnosis.—Scarcely anything need be added to the description already given. The special character of the difficulty is the diagnostic mark of true Writers' Cramp. A man may be unable to write from lead poisoning, but the presence of paralysis rather than spasm; the singling out of certain muscles not only for weakness, but for loss of nutrition and of irritability to electricity in the induced form; the equal affection of the two upper extremities, although, when slight, it may be shown more conspicuously in the hand which writes, and has been educated to perform other complex movements; the presence of a blue line on the gums, and the general history of saturnine intoxication,—are sufficient to establish the diagnosis.

Wasting Palsy, which often commences in the muscles of the thumb, may be known by its characteristic feature, "wasting," and needs only to be mentioned in order to be distinguished from Writers' Cramp. In wasting palsy the loss of power is in direct proportion to the loss of nutrition; in Writers' Cramp, it is the spasm which interferes with the particular movement that is required.

Local Paralysis.—A few weeks ago a gentleman was sent to me with supposed "Scriveners' Palsy." He had been reading and writing much, and on one evening sat reading for some hours "in a draught;"
his hand was weak, and on the following day he could not write. There was when I saw him nearly complete paralysis of the right hand and forearm, and the electric irritability was almost extinct, but in the course of a fortnight the power had returned, and the patient was well. The extent of the paralysis and the absence of spasm were the distinctive marks. Several cases of this kind have come before me, and have been thought to be examples of Writers' Cramp; but the fact of their having been mistaken for the latter is enough to put any one on his guard against a repetition of the error.

Prognosis.—If the case be seen when the symptoms have existed for only a short time, relief may be confidently expected, provided that rest can be given. If the symptoms have existed for many months, or if rest be impossible, the prognosis is extremely unfavourable. There is scarcely any malady which has resisted more obstinately all kinds of attempts—well-directed and ill-directed—which have been made for its cure. Many who were seriously threatened with Writers' Cramp are now free from the malady because they rested; many who could not and did not rest, are now, in the present state of therapeutics, incurable.

Bearing in mind what has been said with regard to the extension of the disease into other regions of the nervous system, some caution is required in stating the general prognosis of such cases, but, in the vast majority, it may be confidently expected that no such extension will occur. When there are signs of disease already present in other directions, such as strabismus, torticollis, weakness of the corresponding leg, and the like, the prognosis should be extremely guarded.

Pathology.—The exact locality of disease, and the precise nature of the change which constitutes it, have not been yet demonstrated with regard to Writers' Cramp. Its closest clinical affinities are with stammering, spasmodic wry-neck, and histrionic spasm, or "muscular tic" of the face. Analogous maladies, but moving in a yet wider range, are sometimes encountered, such as certain forms of rotatory movement, of chorea, and of locomotor ataxy; and beyond these there are anomalous cases, which every physician occasionally meets with, but does not know how to designate. One patient cannot make the attempt to walk without performing, or running in danger of performing, sundry rotatory movements, which terminate in a fall: another, a hard-working clergyman, can only speak, though he has the voice of a Stentor, when on a level with his audience; and this not from any fear, or shyness, or sham, but from definite aphonia. Some of the spasmodic movements induced in frogs by injury to the auditory nerve are of similar character;* and the experiments of Majendie, Flourens, Longet, and Schiff afford further illustrations of analogous disturbances in the physiology of motion.

VOL. II.
In order to understand Writers' Cramp, it is necessary to remember what is, physiologically, involved in the education of the muscles to perform complicated acts, such as those of writing, speaking, or playing on musical instruments. The will does not pick out the muscles which are to be brought into play to hold a pen, it simply directs itself to the result. The boy who plays at marbles directs his movements in the same manner, and with as much accuracy and nicety, as the professor of anatomy directs his when he is writing a description of the muscles of the hand. The combination or co-ordination of muscular contractions is determined by the will, but is effected by another agency. Each is conscious of a wish to do a certain thing, and of a will to do it, but a knowledge of the mode in which the movement is brought about does not help, and may sometimes hinder, its production. Experimental physiology and clinical pathology combine to teach us that a certain portion of the nervous system, the cerebellum, has the power of effecting the co-ordination that is required; and they also unite in proving—what is often lost sight of—that this co-ordinating faculty is guided by sensations, and can act efficiently only when they are normal in kind and intensity. The production of a movement such as writing is therefore a very complicated process, requiring for its efficient performance the integrity of a great number of different parts: viz. that of the will and its immediate exponent in the cerebral hemispheres; that of the nerve-fibres between it and the muscles, together with that of the ganglia which exist on certain nerve-trunks; that of the muscles themselves; that of the cerebellum, as the centre of co-ordination, also that of all the "sensory" nerve-fibres which place it in relation with the organs of special sense, and with the muscles themselves; and, lastly, integrity of the organs of sense, so that they, at the peripheral expansion of their special nerves, can receive impressions in a normal manner. It must be remembered, also, that not only the fact but the degree of contraction is under the control and guidance of the same organs, or parts of organs. Failure in any one portion of this apparatus interferes with the production of the movement that is required; and the kind of failure is determined by the locality of the lesion; or, in other words, by the nature of the process or function which is lost or disturbed. If the contraction of a muscle be acutely painful, the man cannot write, the act would be impossible in some cases of rheumatism; if the muscle be wasted, it cannot be put into the same amount of contraction as in health; if the skin have lost its sensitiveness, all fine movements are awkwardly performed, and the finest are rendered impossible; they may be partially guided by the eye, but the guidance is defective for the most complicated acts; if the motor nerve be damaged, the muscle is pro tanto palsied; if the sensory nerves be injured, sensation is defective; if the sense of muscular condition be in abeyance, the power to control either the kind or force of contraction is without its guide: but locally, i.e. so far as that limb is concerned, all other nerve, muscular, and sentient properties may be intact, and yet spasm or paralysis, or
both, are present. If the will be deficient, and this from any cause, there is palsy, or irregular movement; if the fibres coming between it and the nerve-trunks be injured, there is paralysis in the ordinary sense of the word; if the cerebellum be diseased, there is loss of co-ordination, while power and sensation persist; if the spinal cord be injured, there may be, in relation to the nature and locality of the injury, almost any one of the conditions that have been enumerated.

In true Writers' Cramp, the will, the co-ordinating power in all directions but in one, the motor power, the muscular nutrition and activity, as well as the sensorial faculties, are uninjured; the individual is, or may be, "well" in all respects but one. A particular kind of movement is interfered with, by the occurrence of irregular and spasmodic, instead of regular and co-ordinated, contractions. It must be carefully remembered that the malady is special; the muscles which cannot be made to write can be controlled so as to fasten the most tiresome buttons, carve the toughest of pheasants, or pull a heavy boat. The pianist cannot play on the pianoforte, but he can write as well as ever; the bricklayer cannot use his trowel, but he can do everything else that he wants to do; and in order to understand this, we must revert to what is included in education, and what confers the dexterity which comes of special practice. Many movements are "automatic," we adopt them without education and without effort; others are the result of laborious "practice." It would seem that the body is naturally endowed with certain paths or lines of nerve-action, along which all moves easily. The instinctive movements of the child or of the animal are examples of the mode in which, along these lines, impressions from without pass readily, and become converted into motor impulses, which are, in their turn, conveyed to muscles, which contract, and so perform these instinctive acts. But the process of education, so far as the performance of writing, playing, stitching, &c. is concerned, consists in the frequent repetition, by an act of the will, of certain forced and complicated movements. The repetition makes them easy, until at length they are executed without effort, and almost unconsciously. It would seem that, by this education, new paths are forced, so that what was once difficult and required attention becomes day by day more easy, and at last "secondarily automatic." It cannot be doubted that some changes take place in the nutrition of the parts through which these lines of nerve-action run; and their education that involves structural alteration in the organs. The perfection with which complicated movements are performed in the lower animals appears to be associated with great keenness and remarkable development of the organs of sense; and in man a similar relation may be observed. No man writes well who has not keen sight and a quick sense of touch; no man plays well on the violin who has not an acute ear, and a delicate power of feeling in his fingers. In all instances of educated movement some "sense" is needed, and is an important element in the process by which the result is obtained.
In the present state of science it is not possible to say, for every act, what part of the nervous system is especially engaged in this educational development; but it seems probable that the association of movement is effected by ganglia which are common to fibres passing through distinct but contiguous nerve-trunks, and that it is owing to some nutrition-change in them—the result of persevering and forced effort—that the perfection of movement is produced; associations at first caused by the will, are at last produced unconsciously. What happens, then, in such maladies as Writers' Cramp, is a perverted nutrition of these parts; a worn-out activity, or a degeneration which may arise without over-exertion, and destroy all that had been previously achieved.* The disease, as it has been shown, passes readily from one side of the body to the other; and it must be carefully borne in mind that co-ordination of movement is a most complex process, requiring integrity of sensation as well as of motor nerve and of cerebellum. The real mischief may be some want of limiting and guiding influence ordinarily coming, through sensation, from external impressions. This spasm which occurs is very like that which Mr. Lockhart Clarke describes as taking place in the legs of ataxic patients who cannot regulate the force of their muscular contractions.

**TREATMENT.**—In an early stage absolute rest may do much; in a later stage it may accomplish something; but I know of nothing else which can be called a therapeutic agent. I have tried every form of general and nervine tonic, of sedative, and of local application, but no one of them has been of the least specific value. I have used hypodermic injections of morphia, atropine, and of arsenic, and have found them useless. I have employed galvanism and electricity in all their forms, and have seen no good result. But in many cases perfect rest has removed the symptoms, and it alone seems worthy of being regarded as a means of cure.

Mechanical contrivances for holding the pen may render occasional writing possible, but they do not affect the disease; and persistence in their use has been followed by an extension of the malady to the muscles of the forearm and arm.

* Some of these points in the pathology of Writers' Cramp have been ably treated by Mr. Solly, in the Lectures already referred to in the Lancet of 1865.
HYPOCHONDRIASIS.

By William Withey Gull, M.D. and Francis Edmund Anstie, M.D.

Definition.—A disease of the nervous system, of unknown and possibly varying seat. It is markedly hereditary, being one of the transformed neuroses which descend from a parent stock strongly tainted with insanity. Its principal feature is mental depression, occurring without apparently adequate cause; and taking the shape, either from the first, or very soon, of a conviction in the patient’s mind that he is the victim of serious bodily disease. The sufferer’s belief in this disease is so firm, that he describes minutely the symptoms which, as he fancies, indicate its existence. But he may place the imaginary malady in almost any organ of the body, and he usually describes some symptoms which are anomalous, or even incredible. Finally, Hypochondriasis may be evoked by a real organic disease acting as an irritant to an hereditarily predisposed nervous system; in this case, the anomalous nervous symptoms may mask, and even conceal, the occurrence of serious changes in some viscus.

Nomenclature.—The same name has been applied to the disease since the days of Hippocrates: it has always been known as “Hypochondriasis,” or the “hypochondriac disorder,” and sometimes as the “vapours,” or the “spleen;” but these two last synonymous are, in fact, mere explanations of the ancient hypothesis which was expressed in the word Hypochondriasis. This hypothesis it is really important to say a few words about, since the vulgar conception of the disease still, though unconsciously, cherishes it; although our improved knowledge of the relation of the nervous system to the organism generally has now made it an anachronism.

The words ὑποχονδριακόν πάθος, applied by Hippocrates and Galen to the disease, imply a belief that the viscera behind the xiphoid cartilage, and below the diaphragm,* were its seats; and Galen very distinctly says that black bile is its cause. It is worth while to recall for a moment the physiological ideas which Galen, with great ingenuity, had compounded from the speculations of Plato on the one hand, and

* The viscera of the hypochondria, to which the ancients attached such importance, seem to have been especially the liver, the pyloric part of the stomach, the omentum, the mesentery, and the spleen. The stomach considered as a whole they regarded rather lightly.
Hippocrates on the other. According to Galen, the functions of the human body were maintained by three πνεῦματα (whence, remotely, our "vapours"). The lowest of these was the πνεῦμα φυσικόν, and developed the natural force in the liver; the second was the πνεῦμα ζωτικόν, which elaborated the vital force in the heart; and the third and highest was the πνεῦμα ψυχικόν, which developed the animal or soul force in the brain.* Any one who has been curious enough to investigate these questions will see at once that the lowest or "natural" force of Galen is the counterpart of that lowest kind of mortal soul which† Plato represented as residing in the abdominal organs, and chiefly in the liver, and as having to do with the baser animal passions and the supply of the needs of vegetative life. The ancient tendency to view every source of functional activity as an entity—almost a personality—made it quite consistent for the long succession of Galenist physicians to endow the liver-force with a quasi-consciousness and perception, and even with voluntary activity, though of a low kind; and, on the other hand, the Paracelsian and Helmontian doctrine of the Archeus rather added to than changed anything in the extraordinary power over the general organism which was attributed to the abdominal organs. Then the absence of any accurate knowledge of the functions of a central nervous system, the recipient of sensory impressions, and the originator of motor acts, induced men to localize in the various organs the source of the functional disturbances which appeared to be manifested therein. The vagaries of hypochondriacal sensation were therefore, in the ancient view, the perturbations of the natural force generated in the liver, spleen, and pyloric part of the stomach. It is to be remarked, moreover, that hypochondriasis was very generally confounded with hysteria (to which it doubtless has a relation), quite down to the present century. There is nothing surprising in this. The flatulence which is frequently a striking symptom both in hysteria and hypochondriasis was, for the ancients, a commotion of the natural spirits which resided in the abdomen.

Of the long list of authors who have treated of Hypochondriasis, since the days of Galen, there is scarcely one who viewed the disease in any essentially different light from that in which Galen regarded it, until we come to Thomas Willis, the great investigator of the nervous system. It is easy to see what were the common ideas on the subject at the time by consulting that curious book, Burton's "Anatomy of Melancholy," which was published a few years after Willis's death, and which represented the knowledge which a learned and clever layman might pick up without knowing, or without demeaning himself to notice, the writings of a contemporary countryman. Burton says that the general view of authors represents the hypochondriac or windy melancholy as arising "from the bowels, liver, spleen, or membrane called mesenterium," and quotes Laurentius as dividing it into three kinds, the hepatic, the splenetic, and the mesaraick.

* De Loc. Affect. v. De Usu Part. v. De Usu Resp. 163, 164.
† Timaeus, Ed. Stallbaum, §§ 69, 70.
HYPOCHONDRIASIS.

Willis, on the other hand, placed Hypochondriasis amongst the diseases proper to the diathesis spasmodica; he made it an affection of the nervous system, but so far conformed to the old ideas as to attribute its ultimate causation to impurity of the splenic blood. In the next century, Flemying ventured a more distinct opinion, that the brain was the part primarily affected, and Cullen and Robert Whytt placed great stress on the share which the nervous system has in the production of the disease. The next prominent step was taken by Georget (1819), who protested against the view (at that time still commonly prevailing), of the abdominal origin of Hypochondriasis, and the practice of powerful purgation, &c. which was based upon it. But the most complete and effective attack on the old view was made by J. Falret in 1822. This author dwelt strongly on the hereditary character of the disease, and the great frequency with which it is immediately excited by stress of intellectual labour, or by moral and emotional causes. The view of Falret was perhaps carried to excess in limiting the primary seat of the disease so strictly to the brain; but it has prevailed, and hypochondriasis is now commonly placed among the varieties of insanity. Griesinger, for instance, in his admirable treatise on mental diseases, makes Hypochondriasis a variety of melancholia, which is his first class of "mental diseases characterised by depression;" and Leidesdorf adopts the same view. It will be seen that the view which we hold differs in some degree from this; but there can no longer be any doubt that the true seat of the disease is in the nervous centres.

History.—The history of a hypochondriac patient is that of his nervous system under the two aspects of its congenital form, and the influences—of nutrition, education, and emotion—to which it has been subjected. So far it is not different from the story of the sufferer from any other form of nervous disease. But Hypochondriasis is distinguished by this:—that a more important part is played by the congenital disposition of the nervous system, and a less important part by the physiological and spiritual influences which have been brought to bear on it, than is the case with the majority of nervous diseases. It comes nearest, in this respect, to insanity on the one hand, and to epilepsy and neuralgia on the other. It is the almost inevitable inheritance of a certain percentage of the descendants of any

* T. Willis, Opera Omnia, 4to. Geneva, 1676. The whole treatise, De Morbis Convulsivos, and that on Hystera and Hypochondriasis (in reply to the strictures of Nat. Highmore), are astonishing efforts of genius, and will well repay perusal in the present day.
† Neuropathia; sive de Morb. Hypochond. et Hyster. Ebor. 1744.
¶ De l'Hypochondrie et du Suicide. Paris, 1822.
individual who may be very strongly tainted with insanity. On this subject we shall say no more till we can discuss more fully the etiology of this singular disease.

Symptoms.—This phrase is pre-eminently appropriate to the phenomena of Hypochondriasis. Of physical signs we have almost none to guide us; and this is in perfect agreement with the position which this disorder holds in the category of diseases generally. All is in the region of symptoms. For the most part, too, the symptoms are subjective only: still there are features which the experienced physician can detect, and which can hardly be simulated by a malingeringer.

The most important external feature of Hypochondriasis is this: that without any sufficient reason for such conduct, and without any signs of intellectual insanity, the patient is observed to concentrate his attention on some particular organ of his body, and to fancy that it is seriously diseased. This concentration of attention is often preceded and accompanied by notable depression or variability of his spirits, with a tendency, on the whole, to depression; this is not always the case, however, for there is sometimes no antecedent symptom connected with the general mental state. In many instances the patient's first sufferings take the form of what he himself considers dyspepsia, but which is in fact little more than flatulence, from the formation of large collections of gas in the stomach and bowels. Along with this flatulence, there are sometimes appearances which give a superficial colour to the idea of a primary stomach derangement: the tongue, for instance, is often pasty and coated, and there may be foul breath; the appetite is not unfrequently ravenous, capricious, or well-nigh lost; there is generally obstinate constipation; in rare cases there are even attacks of vomiting.

More commonly there is an antecedent mental change, the character of which it is at first difficult to seize, and which forms one of the grounds for the modern practice of including Hypochondriasis in the varieties of actual insanity. Before any local symptoms have declared themselves, the patient has already become changed in his disposition; in most cases, perhaps, the change is simply in the direction of despondency or vague alarm, for which he can give no reason. It is remarked by alienists that the mental condition, even thus early, is characterised above all things by an expansion of the self-feeling, a pre-occupation of the patient with his own condition, to the exclusion of other interests and affections. This is true, but it appears to us that the self-concentration is more like that of a person in the preliminary stage of an acute inflammation or fever, the nature of which is not yet declared, than the egotistic alteration of character which seems to lie at the basis of insanity, and which probably depends directly upon minute changes taking place in the cortical substance of the brain. It is a real bodily sensation (though at first indescribable), which enchains the sufferer's attention; and before long this vague feeling is exchanged for a positive localized sense of uneasiness or actual pain.
HYPochondriasis.

Sometimes the early mental state is one not merely or chiefly of despondency, but characterised by suspiciousness and irritability of temper, with quick changes from high spirits and loquacity to moody silence. In any case, after a time, the patient not only exhibits in his aspect and conduct the general uneasiness from which he suffers, but begins to complain of definite subjective symptoms. Probably the most common of these is pain of a gnawing or burning character, or else a sense of great though vague uneasiness at the pit of the stomach. But in fact any part of the peripheral distribution of the sensory nerves may be the apparent seat of painful sensation, and besides this there is very often a general heightened sensibility of the skin. Both the active pain and the heightened sensibility of (uncomplicated) Hypochondriasis are subjective, and resemble the similar phenomena which are so common in hysterical women, in vanishing when the patient's attention is powerfully diverted from them. The painful sensations of which hypochondriacs complain are very acute; and their severity concentrates the attention of the sufferer exclusively upon them, increasing the apparent egotism of his disposition. But it may here be remarked, that the heightened self-feeling of Hypochondriasis does not partake of the despondency of true melancholia, still less of the character of other forms of insane egotism. The patient (as observed by Leidesdorf), though depressed in mind, not only wishes to get rid of his malady, but has great faith that he shall do so: a faith which suffers repeated shocks, indeed, from the non-success of particular remedies, but quickly revives in favour of some new mode of treatment. The eagerness with which he pursues the means of cure is the true cause of the limitation of his thoughts.

Next to pseudo-dyspeptic symptoms, and the occurrence of pains or anomalous feelings at the pit of the stomach, the most common morbid sensations in Hypochondriasis are, probably, formication of the skin, and burning pains in the course of particular superficial nerves. It is noteworthy that, so far as we are aware, the nerve-pains most frequently assume the burning type, rather than the lancinating, throbbing, or aching forms which neuralgia more commonly takes. A common occurrence is the sudden shifting of the pains or the sense of formication from one part of the body to another, or their sudden extension from a small area which they first affected over almost the whole surface of the body. Another very frequent subjective symptom is the feeling of pain, or great but indescribable uneasiness deep in the heart, or the lungs, or the liver, the bladder, or the rectum. The development of the subjective symptoms is very often seriously influenced by the fact that the patient is driven by his misery to consult medical books, or to pester his medical friends with questions bearing on his sufferings: his defective knowledge and distorted fancy lead him to apply, à tort et à travers, the scraps of information which he picks up, and to imagine, successively, that he has discovered in himself the signs of one, two, or half-a-dozen serious organic diseases. Attention being thus directed to particular organs,
the subjective symptoms naturally increase and multiply, and the emotional excitement produced also frequently sets up severe functional disturbance, such as flushings of the face, abdominal pulsation, palpitation of the heart, partial suppression of bile and jaundice, or bilious diarrhoea; symptoms which still further confirm the sufferer in the belief that he is labouring under serious organic disease. A very common delusion is the belief that there is fatal heart-disease; and a scarcely less frequent one is the persuasion of the patient that he is impotent from spermatorrhoea: this last is of course greatly fostered by reading pseudo-medical treatises. In the case of patients whose family is strongly tainted with insanity, the anomalous sensations often assume a type which approaches to hallucination or illusion (as where there is the belief that a serpent is writhing about in the entrails, &c. &c.), or the judgment becomes affected to such a degree that the patient entertains presposterous delusions (as that he is made of glass, and in danger every moment of being broken, that he is being magnetised, that people are conspiring to poison him, &c.). The delusions sometimes are confined, at any rate for a time, to one or two organs, but are nevertheless so extravagant that it would really seem no paradox to say that the patient has a mad stomach, a mad liver, or a mad bladder; while on all other matters his intellect remains healthy, and often unusually acute. But on the subject of the Protean symptoms of hypochondriasis it is really unnecessary to enlarge further, and we may refer those who desire to read a truthful and highly picturesque description of them to the pages of Burton,* to say nothing of more modern writers.

**Diagnosis.**—The diagnosis of Hypochondriasis, from maladies superficially resembling it, is proverbially beset with difficulties, and the practitioner can only gain confidence in his decision on the more doubtful cases by means of long experience. Nevertheless, the general principles on which his judgment must be formed are not very difficult to state.

If the anomalous character of a patient’s subjective symptoms points in the direction of Hypochondriasis, the very first subject of inquiry should be the family history. A well-defined history of insanity in the race would at once indicate the probability that the patient’s sensations were partly illusory, and not referable to their apparent site. On the other hand, a decided history of the absence of insanity and of the other severe neuroses from the family during two or three previous generations, would still more strongly suggest that the case was not one of Hypochondriasis. The next point for investigation would be the mode of commencement of the illness. A history of the primary occurrence of severe bodily symptoms, whether in the shape of pyrexia, of disturbance of hepatic or gastric functions, or of pain in the course of nerves, is unfavourable to the diagnosis of Hypochondriasis, unless these phenomena were preceded or accom-

* Anatomy of Melancholy, pp. 270—274.
HYPOCHONDRIASIS.

panied by psychical changes such as have been already described. Even a more chronic development of capricious pains, of formication of the skin, of flatulence, palpitations, and the like, is not specially indicative of Hypochondriasis, unless there is unusual anxiety on the patient’s part, and an egotistic tendency to dwell on his sufferings. A great deal may be gathered from considerations of age and sex. Hypochondriasis is pre-eminently a disease of adult and middle life; it is hardly ever seen before puberty, and it very rarely makes its first appearance after the age of fifty. It is greatly more common among men than among women; in the latter sex it appears to be replaced, for the most part, by hysteria. Still Hypochondriasis may occur in women, and the question of diagnosis from hysteria, in such a case, becomes important, and may be very difficult. Beyond all other circumstances which favour the probability of Hypochondriasis is the fact of a strong hereditary taint of insanity. The age at which the symptoms commence is important: thus the first appearance of hysterical phenomena nearly always takes place between the ages of fourteen and thirty, or else at the grand climacteric; and has very commonly a marked relation to those changes in the nervous system which correspond with the changes of the sexual apparatus; whereas the development of Hypochondriasis is especially associated with the circumstances of middle life—in the rich and idle with the tedium vitae of a purposeless existence; in the poor and anxious with the cares of a family, and perhaps with the added misery of a conscious failure in efforts to support relations and dependants. Severe moral and emotional shocks may be followed either by hypochondriacal or hysterical disorder; but the latter is the infinitely more probable result in women who are not descended of markedly insane families, and especially in women who lead busy lives.

One of the most important questions in diagnosis is the decision whether, if Hypochondriasis be present, there is not at the same time some organic visceral disease; for it sometimes happens that the first sign of the occurrence of such disease is an outbreak of hypochondriacal symptoms, the patient being hereditarily predisposed to the latter disorder, and his nervous system excited to morbid action by the irritation of the new organic processes which are going on. Of the diseases which have been known to produce such an effect, structural changes of the liver, and, next to them, structural changes of the stomach, are probably the most frequent examples; and, after these, aneurisms of the great vessels, valvular diseases of the heart, angina pectoris. It is unnecessary here, even if there were space, for us to go into the characteristic symptoms of these organic diseases. The first feature which may lead the physician to suspect the existence of organic visceral disease in the midst of symptoms which he feels sure are hypochondriacal, is the persistence of some one complaint by the patient—e.g., of pain in a particular locality: especially if this be combined, always in the same order, with other symptoms that belong to the suspected organic disorder, and with which the patient
is not likely to be acquainted so as to be mentally influenced to reproduce them. Thus if, along with a fixed complaint of pain in the precordia increased by swallowing, there is the regular occurrence of regurgitation of some of the food very shortly after deglutition, it is a case for inquiry as to the possible existence of cancerous or other stricture of the cardiac end of the stomach, &c. It is needless to say that physical signs, when they are present, are the most valuable helps in discerning organic disease which is masked by Hypochondriasis; yet even here there is need for caution. For instance, the occurrence of hardness and tumidity in the epigastrium or the hypochondrium, in such a form as closely to imitate a scirrhous tumour (even on repeated examinations), may be produced by spasmodic contraction of one or both recti; in such a case the administration of chloroform would at once dismiss the suspicion by dissolving the "phantom" tumour. A circumstance which is always of doubtful interpretation is the occurrence of wasting, especially if combined with jaundice. If this takes place with rapidity, it can hardly be owing to hypochondriacal disturbance of digestion and assimilation, but is probably due either to the generally depraving effect of cancerous or tubercular taint, or to direct interference with nutrition from the mechanical effects of ulcer, stricture, or tumour, upon some of the chylopoietic viscera. The combination of insidious and unsuspected malarial poisoning with hypochondriacal tendencies may produce formidable difficulties in diagnosis, which can only be overcome by careful study of the patient's past history, sometimes by the discovery of enlarged spleen, and above all by the effects of anti-periodic medicines. Another variety of blood-poisoning, which in hypochondriacal patients may be somewhat masked, is chronic alcoholism; but it has been shown, in another article in the present volume, that the symptoms of the latter complaint are, after all, tolerably distinct and recognisable from their peculiar grouping, and even in a hypochondriac they may generally be identified.

A more serious difficulty in diagnosis than any which has yet been mentioned is the distinction between certain forms of hypochondriasis and true melancholia. Given a patient with a decided family history of insanity, with a mental condition marked by a strong tendency to dwell on complaints of bodily misery, and with dyspepsia and flatulence, it may be very difficult to say whether or not the case will pass into true melancholic insanity. The following case will give a good idea of the occasional uncertainty. A postman, aged forty-three, a widower, was much overworked, and especially harassed by having to sort the letters in the morning before he started on his beat, a task which had to be hurriedly done, and hence gave him much anxiety lest he should make mistakes. He applied for relief from dyspepsia and flatulence and bilious diarrhea, but at the same time complained that his spirits were dreadfully low, that he had thoughts of suicide, and that he believed he had "something alive in his inside." A simple tonic mixture of mineral acid and bark, combined with the moral influence of
HYPOCHONDRIASIS.

encouraging assurances from the physician, did this patient so much good that he soon seemed perfectly well, and remained so for some months. He then got married again, and his marriage apparently embarrassed his means, though not seriously; but his despondency now returned in the form of a belief that he and his family would have to go to the workhouse (of which there was really not the least danger), and the impulse to suicide again became very urgent. At the same time his dyspepsia and bilious diarrhea returned. He applied for medical relief, was ordered the same treatment as before, and was encouraged to hope for a speedy cure; but the very next day he attempted suicide by completely severing the whole of his genitals from his body with a razor. He was taken to St. George's Hospital, and with great difficulty kept alive while the wound healed. Six weeks after his discharge from the hospital, he appeared before his former attendant, looking fat and fresh-coloured, but more despondent than ever, indeed; plainly insane. He was then lost sight of, but there could be little doubt that he would get worse, and, if not carefully watched, would commit suicide.

Such a case as the above has little to separate it from Hypochondriasis except the one important feature of the early occurrence of suicidal despondency; but this feature would probably be sufficient justification for a decided diagnosis. It is only where the hypochondriac patient has been exhausted by a long continuance of his sufferings and rendered hopeless by the failure of a thousand attempts at cure, that he turns his thoughts to self-destruction, and by that time he may be considered really insane. Indeed, the hypochondriac proper regards the idea of suicide with the utmost repulsion and disgust.

There is no serious difficulty in distinguishing simple Hypochondriasis from the other forms of insanity.

Prognosis.—The prognosis of Hypochondriasis varies extremely, not so much with the apparent severity of the symptoms, as with the circumstances under which they arose, the length of time during which they have already persisted, and above all the degree to which the patient's family has been tainted with insanity. But in general it may be said that the younger the patient, the shorter the time during which he has suffered, the less that the nutrition of the body has deteriorated, and, above all, the less of decided family taint of insanity that can be traced, the more hopeful is the aspect of the case, and vice versa.

Etiology.—The "causes of Hypochondriasis" is an expression even more singularly unhappy than the average instances of a phraseology of causation applied to those circumstances which precede the outward and visible development of functional disorders. To commence with those influences which have a conventional title to be called "exciting" causes; it is undoubtedly true that in a considerable number of cases the train of disastrous events has seemed to be fired by the moral collapse consequent on over-exhausting labour, or bitter
disappointment of cherished hopes, or on the sudden revelation to the mind of an idle man that he is a mere burden on the face of the earth. Again, it is commonly said that reading or conversation on medical topics often frightens laymen, and, more rarely, even doctors, into a nervous and hypochondriacal frame of mind. There is, doubtless, something to be attributed to such influences, but the most thoughtless person could hardly fail to be struck, on reflection, with the surprising infrequency of Hypochondriasis in comparison with the ubiquitous operation of such influences as grief, fatigue, the sense of shameful failure, the habit of miserable and heart-wearying idleness, and the practice by the laity of reading medical treatises. If we turn to the events which would be conventionally spoken of as "predisposing" causes, we are scarcely likely to be more satisfied with the appropriateness of the term "cause;" though we come upon facts of far greater practical value than those which have just been mentioned. The fact of hereditary insane taint, for instance, is an antecedent which is observed in an immense number of cases, if not in all. The preponderance of males among hypochondriacs is equally unmistakeable, and so is the fact that the bulk of cases occur in persons in the prime and vigour of life. It is also an undoubted fact that the average level of intellect in hypochondriacs is not below, but rather above, the general standard; and that their bodily health has often been excellent up to the moment when the nervous symptoms made their appearance. But instead of saying that these circumstances are "causes" of the disease, it will be convenient to say that they are conditions of its occurrence in the following degree and manner. A certain number of the descendants of a family strongly tainted with insanity will invariably be born with peculiarities of the nervous system; these peculiarities do not, probably, consist of recognisable structural faults, but rather of tendencies of one or more (perhaps scattered) portions of the central system, to change interstitially in a certain morbid direction, at particular crises of life, through which healthy organisms pass unharmed. Arrived at such crises the nervous system will surmount them, or will succumb, according to the absence or the presence of certain external disadvantages. If the morbid change occurs, it will not affect the machinery of the intellectual and reflective faculties chiefly, perhaps not at all; its force will be spent mainly on that portion of the nervous apparatus which performs the function of translating to the mind the perceptions of sensitive nerves at the periphery; but it is not impossible that even the primary morbid action is occasionally developed in nervous centres which govern secretion and other functions of organic life; and that the dyspepsia, and other functional disorders of viscer, may in these cases be the direct result of a central disease, instead of reflex phenomena dependent upon the condition of consciousness, as is probably the case in many instances. In the later stages of the malady there can be no doubt that the mental depression reacts with great force upon the machinery of organic life, disordering secretions and rhythmic motions very extensively.
The Pathology of Hypochondriasis, in the strict sense of the word, does not exist, for there are no anatomical or physiological facts upon which it can be based. Morbid anatomy has revealed absolutely nothing which in the slightest degree explains the occurrence of the disease; and the physiology of the symptoms is to the last degree obscure and uncertain in its interpretation. It is only in those cases which develop into true insanity, more especially those which pass into dementia, that the brain exhibits any notable changes; and these alterations, when they occur, are no proper part of hypochondriasis. It is neither impossible nor unlikely that the improved modern methods of examining the nervous centres, if they could be applied to the central ganglia of certain visceral nerves (and especially to the nucleus of the vagus), might detect appreciable changes even in the early stages of the disease. But the opportunities for carefully examining the nervous system of patients in the early periods of Hypochondriasis can rarely be obtained, and it is probable enough that the question as to the pre-occurrence or not of structural changes will never be thoroughly cleared up.

The Treatment of Hypochondriasis consists of the use of moral and constitutional remedies and of remedies for symptoms. It is obvious that the first duty of the physician is to encourage the hypochondriac to forget his woes; but nothing is so difficult in practice, and that for the best of reasons. It is a fallacy to suppose that the sufferings of the patient are unreal; on the contrary, they are most vividly real, and it is impossible that he should forget them till they cease. Yet the mind has a reflex influence upon the bodily disorder, which may be as effective for good as for evil; and this fact may be taken advantage of. The key to the moral treatment is the breaking down of the patient's morbid self-concentration, and this object may be achieved to some extent in many cases by a change in the course of his daily life. The class of patients with whom this may be most readily carried out are those in whom the constitutional tendency to Hypochondriasis is aggravated by the ennui of an idle life: for these, an active career or pursuit of almost any kind is an immense gain; only the new occupation should be one which forces them to mix with the world. The isolated activity of the student is no real diversion from the fancies of Hypochondriasis, as the case of Dr. Johnson, and of many other famous intellectual workers, abundantly proves. It is needless to say that all actively depressing influences should be removed, such as immoderate venereal indulgence, of whatever kind, or alcoholic intemperance. On the other hand the influence of new emotions which tend to lift the patient out of himself can scarcely fail to be beneficial; and it would be a real good fortune to a hypochondriac if he could fall in love in a natural and healthy manner, or if he could interest himself warmly in philanthropic schemes, or other plans of public usefulness. And above all, something like a police supervision should be exercised as
regards his studies, in order that he may be rigorously kept from the perusal of medical or other books which might remind him of his miseries; for though we do not believe that these things can create Hypochondriasis, yet they may certainly prevent its cure. It is well understood, however, that no good can be effected by simply laughing at his narrative of suffering, or bantering him on his fancifulness: on the contrary, it is necessary for the physician to be interested, and to believe in the reality of his painful sensations. If the patient once thinks that the doctor is taking pains to get at the secret of his troubles, he will be inclined to accept the first word of encouragement the latter throws out; and the reflected influence of reviving hope will be certain to assist recovery.

The *constitutional* treatment is to be directed towards improving the general nutrition; and the task here is partly that of aiding the primary process of digestion of food, and partly that of rendering more active the processes of decomposition and exchange in the tissues generally. The hypochondriac either has a deficient, a capricious, or a ravenous appetite, but in any case the primary function of digestion is almost always markedly impaired if the disease has lasted for any length of time; and when this depends on a want of tone mainly, or a condition of irritation of the stomach (such as is indicated by a coated tongue with a red or strawberry tip), the use of vegetable bitters and mineral acids will often do great good. Defective secondary assimilation, which will be especially indicated by the condition of the urine, is generally much benefited by the use of cod-liver oil for a rather prolonged period, if only the remedy can be tolerated by the stomach. In cases where the oil cannot be borne, cream, butter, or some other form of fat, will often agree, and may be made the first stage to inducing the stomach to retain the cod-liver oil. Nor is it by any means only in cases where there is general emaciation that the administration of fat does good; it is probable that the nutrition of the nervous tissues is directly improved by the treatment in many instances. The administration of iron is doubtless of great use to some anaemic patients, and sea-bathing frequently appears to exercise a very beneficial influence; but the first of these remedies is generally most efficacious when taken in the form of the chalybeate waters of some foreign spa; and there is good reason to doubt whether both mineral waters and sea-bathing do not owe most of their apparent power to the moral influences of travel and change of scene and mode of life. The more specific nervous tonics, such as strychnia, quinine, or phosphorus, seem to exercise but a doubtful and accidental influence.

The treatment of symptoms is a thing to be eschewed in Hypochondriasis, with certain special exceptions. While, however, it is desirable to avoid concentrating the patient's attention on parts which are the apparent seat of mere morbid sensations, it is important to relieve him of the distress caused by real (though mere functional) disorders of the digestive system. Decided acidity of the stomach
HYPOCHONDRIASIS. 

should be counteracted by the use of antidotes, of which none is more efficacious than magnesia ponderosa, in ten-grain doses thrice daily, or Brandish's solution of potash, ten minims three times a day, with gentian or cascarilla. The excessive or too long continued use of alkalies is, of course, to be avoided. The distressing flatulence, which is often one of the earliest, and also one of the most annoying symptoms, is greatly relieved by creosote (one drop in a pill twice or thrice a day), or the infusion of valerian. Alcoholic tinctures should be very cautiously employed, if at all; for there is a real danger of the patient coming to appreciate the comforting sensations given by the spirit so highly, that he gradually takes to drink; this is especially true in the case of hypochondriacal women, as it notoriously is in hysteria. We may add that it is particularly likely to occur in patients exhausted by masturbation, or other venereal indulgence. The constipation, which is frequently so obstinate and troublesome, must be remedied, if it be anyhow possible, without the use of drugs; for it is most dangerous to stimulate the patient's love of self-doctoring in the direction of the habitual use of purgatives. The prescription of fruit, green vegetables, &c. as articles of daily food, is a far more desirable mode of accomplishing our object; and the habitual practice of active bodily exercise is a powerful aid to the same end.

The question of the quantum et quale of physical exercise which may be beneficial in hypochondriasis forms a fitting subject with which to conclude our remarks on treatment, since this is a remedy which directs itself alike to the moral, the constitutional, and the symptomatic condition of the hypochondriac. The only rule, however, which it is possible to lay down for our guidance in this matter, is the direction to employ physical exercise in such a manner and to such an amount as shall fully exercise the muscles without ever producing severe fatigue, and shall also be amusing to the patient. It is a very dangerous error to carry exercise to the fatigue point; a short continuance of such malpractice will usually suffice to produce a profound deterioration of the vigour of the nervous system, and an aggravation of the hypochondriacal fancies.
HYSTERIA.

BY J. RUSSELL REYNOLDS, M.D. F.R.C.P.

The most characteristic feature of Hysteria has been held to be a particular form of convulsion, which will be described hereafter in detail; but there are many phenomena, falling far short of convulsion, and differing widely from it in their form, which have been termed "hysterical." While, therefore, by the word "Hysteria" is intended a definite disease, the term "hysterical" may be employed with a no less definite aim; although it has been sometimes used to denote either a mere variety of the nervous temperament, a mood or disposition of the health of both body and mind, or sometimes a vague condition of disordered function which cannot be conveniently placed elsewhere. The employment of the word "hysterical" may sometimes be found indicative of the state of mind of the practitioner rather than of that of the patient's health. It simply conveys a doubt as to what is the matter, but expresses a prevailing conviction that it is nothing very serious as to life, and that it might culminate in an attack of convulsions of the kind called "hysteric."

The vast preponderance of Hysteria in the female sex has given rise to its name, and to a theory as to its essential nature and mode of production. It has, however, and especially of late years, been so distinctly shown that Hysteria may exist among men, that the older nomenclature, although retained on account of its practical utility, is virtually exploded as to its etymology. Hysteria is not necessarily associated with disease or derangement of the generative organs of either sex; such association may, and does very commonly exist; but the true nature of the malady may be overlooked if regard be paid exclusively to that particular relation.

The hysterical condition may exist for many years, and yet be unattended by any distinct convulsive paroxysm. The latter never exists without the former. There are at the present time numberless individuals whose lives are, to themselves and their friends, the source of more or less constant misery, from the fact of their being distinctly and definitely hysterical, but in whose history there has never occurred a single attack of characteristic convulsion. We cannot, therefore, draw the line of definition so as to include the paroxysm and exclude all beside; but must, on the other hand, regard as essential that which is constantly present, and recognise, as the disease Hysteria, a general
condition of the nervous system of which the paroxysm is only one, although a highly important feature. The mental state of the hysterical patient is more constantly and as characteristically altered, as is the condition of the muscular system. There is a defective or perverted will; an increased activity of emotion, and sometimes of thought; an altered and augmented general sensibility; an exaggeration of all forms of involuntary motility—ideational, emotional, sensational, and reflex; and usually some distinct perversion of the physical health. It is almost impossible to frame an accurate "definition" of the disease; and it seems to me more desirable to make the above general statement, than to attempt a less detailed description for the purpose of giving it the form of a definition.

Natural History.—I. Causes.—Sex. Doubtless the most frequently predisposing cause is that condition of the nervous system which is more or less characteristic of the female sex. Hysterical women are met with daily; hysterical men and boys are of comparatively rare occurrence. When Hysteria is found in either a man or a boy, it is to be observed that such person is, either mentally or morally, of feminine constitution, or that he has been overworked mentally, exposed to much emotional disturbance, or greatly reduced in physical power. The predisposition to Hysteria does not exist in the fact of an individual having the organs of one or the other sex, but in the possession of a nervous state,—an habitual, constitutional, or induced relation between the several elements of mental, moral, and physical life,—which is common to, but not always possessed by women; unnatural to, but sometimes exhibited by, men. Some women are as little likely to become hysterical as some men are to fall pregnant; they are of masculine build, both mentally and bodily, and their existence and their predispositions to disease furnish another proof of the truth of the general proposition, that it is in the nervous endowments, and not in the nature of the reproductive apparatus, that the special predisposition lies.

Age.—In the female sex, Hysteria usually commences at or about the time of puberty, i.e. between twelve and eighteen years of age; but, when once developed, the symptoms may remain throughout life. At the climacteric period Hysteria may become developed in a previously healthy person; but this is, comparatively speaking, rare. Of 351 cases analysed by Landouzy,* the ages at commencement were distributed as follows:—

<table>

</table>

Boys sometimes exhibit hysterical symptoms at puberty, but the most marked cases of the disease that I have seen in males have been at a more advanced age, viz. from thirty-five to fifty and upwards.

Temperament.—If by nervous temperament be meant simply an hysterical condition, it is unnecessary, and would be wrong, to speak of the one as a predisponent to the other. The two expressions are sometimes used interchangeably, but this is a great mistake; the truly nervous temperament implies no disproportion, inter se, of the several nervous endowments; all are alike active. There may be in those of nervous temperament a higher but a shorter life; an intense vitality, which burns itself out before its time; but the hysterical condition is essentially one of disproportion, and it is not encountered with any especial frequency in those who have previously exhibited the exaltation described. This latter is peculiar to some individuals, but is not necessarily morbid.

Sexual Condition.—Undoubtedly Hysteria is more common in the single than in the married, but it is not limited to the former, and it may exist to its highest degree in the latter. It is said that the wives of incompetent husbands, and barren women, as well as widows and old maids, are frequent victims of the hysterical malady: but statements such as these do not convey the whole truth in regard of the etiology of Hysteria; and it must be remembered that Hysteria is met with in those who are happily married, in pregnant women, and in nursing mothers.* From what has already been said in regard of the age at which the disease begins, it is obvious that age, rather than sexual condition, is the predisposing cause. Hysteria commences at a time of life when girls are, in this country at least, held to be too young for marriage. The fact of its existence, to a high degree at any rate, does not increase their social chances in this particular; they often remain single because they are hysteric, and this probably quite as often as that they become hysteric because they are single. Such a condition does not tend to improve itself, and the disappointment of being left alone may keep up and exaggerate the morbid state. The facts that there are to show that marriage has sometimes cured the malady are not so numerous, nor are they of such character, as to outweigh the evidence to be derived from the persistence, and even aggravation, of Hysteria after marriage. It is comparatively easy to shrug the shoulders, and utter inuendos over a case which baffles treatment by well-directed regimen and medicine; but does it not sometimes happen that such hints are only a clumsy excuse for the failure of therapeutics? Marriage may be of use in Hysteria by other than its more sexual relationships; there may be a number of circumstances which are changed by taking this step in life; annoyances may be removed, new purposes conferred, work given to do, and strong help rendered kindly for the doing it; and all these may concur to lift the hysterical woman out of her former self. If, then, we are regarding Hysteria etiologically,

all these points should be considered, and the argument from the effects of marriage should not be based upon one element alone.

Sexual excesses are held to be sometimes productive of Hysteria, and doubtless they are so occasionally in men, but there is a deficiency of evidence to prove this in regard of women. According to Du-chatalet, Hysteria does not exist with especial frequency in women of the town, and those who are exposed to excesses of this kind.

Temperature, Climate, and Season.—There are many facts to show that warmth of climate, and that the seasons of spring and summer conduce to a production of the hysterical condition, but it has yet to be shown what is the element comprised under those terms which is of etiologic moment.

Occupation.—It is demonstrable that absence of employment, as it is commonly met with among the upper classes, favours the production of Hysteria in women; and it is equally clear that overwork, anxiety, and great "strain" upon the intellectual and moral faculties, lead to the development of Hysteria in man. It is, however, questionable whether the mere fact of occupation, or its kind, is either favourable or unfavourable to health or to Hysteria. The unoccupied life of woman is one of exposure to numberless disturbing causes, as is also the over-occupied life of man. The woman, or the young girl, who has nothing to do—nothing serious to which her mind is turned—finds "time" to be egregiously tedious; and she has to choose between two evils, either that of "doing nothing" with it, or that of "getting rid of it" by utterly frivolous pursuits, the distraction of reading silly books, and doing the sillier things that "society" prescribes. The man who is "over-worked," finds, commonly, in that work much more than mere mental occupation, viz. anxiety, suspense, and worry, with their concomitants, loss of both appetite and rest; and it is these which, by the nature of their operation, develop the hysterical condition, rather than the amount of simple work which has to be undertaken or pursued. It is then, I believe, neither the presence nor absence of occupation, per se, which conduces to the development of Hysteria in either sex; but in the one sex the "nonsense" that takes the place of sober work, and, in the other, the emotional disturbance that attends upon over-exertion. These lead, under apparently dissimilar circumstances, but in a really analogous manner to the production of the same result.

Menstruation.—It has already been said that Hysteria breaks out most frequently at or about the time of the commencement of puberty; but it has not yet been shown that it has any definite relation to the varying conditions of menstruation. In an individual already hysterical, there is more than usual disturbance at or near the monthly "periods," and this is exaggerated by any kind of irregularity which may exist. Menorrhagia, by reducing the vital power, through loss of blood; Dysmenorrhœa, by effecting the same result through nervous exhaustion; or Amenorrhœa, by its physically direct, and mental and morally indirect influence, may, either of them, conduce to the
increase, or even development of the hysteriac state; but it has yet to be shown that either one of these is of itself sufficient to produce the disease. For, it must be remembered that Hysteria may exist to its highest degree,—it commonly has done so in the cases which have fallen under my own observation,—in individuals who have presented no anomaly whatever in regard of the menstrual functions; and, yet further, that it is found in the male sex, which may be influenced much by sexual conditions, but which exhibits nothing analogous to those perturbations that have been mentioned. All that I can add to the above is, that I have found no one condition, either of excess, defect, or perversion of the menstrual function, so commonly or pre-vailingly associated with Hysteria as to give to it any special claim to consideration in the etiology of the disease. Some people become more or less hysterical about everything that is wrong in the performance of their functions; it is both obvious and notorious that the uterine functions are invested in the minds of women with an amount of importance that is more than their physiological due; and hence it is that menstrual derangements are regarded by them as exerting much more influence than those of the digestive or the excretive functions, and are therefore brought prominently forward in the statement of their cases. That they do exert this excessive influence may be due partly to their intrinsic nature, but partly also to the results of thought and feeling about them; and it is important to bear in mind, for etiologic purposes, this latter element in their mode of action.

Hereditary taint has not been shown to exert any marked influence in the development of Hysteria. It is well known that members of one family occasionally exhibit similar symptoms, but then it must be remembered that many conditions besides those of blood-relationship are ordinarily common to the individuals of one family; they may share equally in what is good or bad in respect of example, education, and surrounding circumstances. M. Briquet states that those who are born of hysterical parents are twelve times more liable than others to the outbreak of Hysteria. Very different numerical statements are made by others, and we must remember that besides hereditary taint there is much contingent upon having an hysterical mother.

The most frequent determining cause of an outbreak of hysteriac symptoms is some mental or moral disturbance; either a violent and unexpected commotion, or more commonly the occurrence of a trivial circumstance which takes the individual by surprise, overcomes the power of restraint, and gives evidence of what is often an ill-understood but long concealed, annoyance or distress. It then appears, and sometimes to the surprise of even the most intimate relations, that there is a morbid condition of both mind and body which is difficult to describe, and often much more difficult to manage. There may be the extreme symptoms of the hysteriac paroxysm, or some of the marked features of the hysteriac state. These have now to be described.
II. Symptoms.—It is convenient to separate the paroxysmal symptoms from those which exist in the intervals of attack; and the former will be best understood by those who have become acquainted with the latter, for the hysterical state does much to explain the hysterical paroxysm.

It will be well to divide the interparoxysmal symptoms into several categories, describing separately the condition of the mental and emotional, the sensorial, motorial, and general health.

(a) Interparoxysmal Symptoms.—Mental and Emotional State.—
The will is perverted and defective, while ideas and emotions exhibit excessive activity. The patient says that she cannot do this, or cannot bear that; and, while under the belief that these things are impossible, they are so. It is often obvious to others that no physical impossibility exists; but it must not be supposed, therefore, that the patient is pretending or "acting a part." For the time being it is often true that the hysterical patient states the fact. What she wants is motive, and this may be sometimes supplied by a sudden alarm, or by an accidental circumstance, but under ordinary conditions the motive is wanting, or is held in abeyance by some imperious idea or emotion. There is an exaggeration and perpetuation of what exists in all people under certain circumstances. Fear paralyses the strong man, while sudden alarm may make the weak man strong. A prevailing idea may limit as well as induce movements which the will can neither counterfeit nor hinder. Let this be remembered, therefore, at the outset in describing the symptoms of Hysteria.

The patient asserts that she cannot control her thoughts, emotions, expressions, or general movements; that she cannot move this or the other limb; cannot open the eyes; cannot stand or walk; cannot relax the rigid spasm of the hand or of the leg; and what she says is true under the existing conditions. But often, under the influence of some unexpected idea, or emotion, or sensation, she does the very things that were said to be impossible.

A patient may be carried into the room, and may fall when left for a moment to herself; tell her to walk, and a wooden doll seems as capable of movement; but, under the stimulus of a wish that what she is saying should not be overheard, she walks to the open door and closes it. Certain ideas seem rampant in her mind, she cries about them, and gesticulates in the wildest manner; tell her to be silent, to keep them to herself, or to control her feelings, and you find them exaggerated, and she affirms that "all the world shall hear" what she has to say; but a gentle rap at the door, that may come from the hand of some one from whom she wishes to conceal her state, is sufficient in a moment to hush this stormy talk, to compose her face, to dry her eyes, and make her speak and smile with placid composure. Sometimes she speaks in a whisper only, and if asked to "exert herself," or "make an effort," so that some particular friend who is a little deaf may hear what she has to say, the only effect is that the whisper
becomes quite inaudible, that she makes less sound than ever, and often none at all—she moves her lips, but not even the ghost of a sound is heard to pass them; and yet this self-same person may, when no attention is directed to the voice, speak loudly enough to be heard and understood in the adjoining room. The fact seems to be that the will can be called into exercise only by some one dominant idea or emotion; and that it is this which determines the varying phases of the mental state. Under its influence the hysterical patient may submit to pain, annoyance, and privation such as a healthy person would shrink from without concealment; and under its influence, also, she may be unable to do what any one else could accomplish without either difficulty or fatigue.

Ideation is often excessively active in regard of certain classes of thought; there is sometimes quite a preternaturally acute condition of intelligence in certain directions, i.e. in those directions wherein lie the morbid notions which are at the foundation of the malady. Often the hysterical patient makes many mistakes, and attributes to people and circumstances motives and meanings which they do not possess; but very often she exhibits marvellous ingenuity in perceiving the ideas of others, and in unravelling the intention of complicated conditions, when these have happened in any way, or to any degree, to have had relation to herself. Apart from these direct personal relationships the mind often is, or seems to be, a perfect blank; the patient is listless, apathetic, and dull; a most uninteresting specimen of humanity; becoming of value only when her vagaries afford curious illustrations of certain pathological laws. There is a prevailing belief in the importance of self, and the patient thinks that she differs from every other human being; that ordinary laws do not apply to her; that she is "not understood," as the phrase is; and that only some very outre, or utterly novel mode of treatment can do her any good. She believes all this, and acts upon it with a pertinacity "worthy of a better cause," exhibiting as much energy of purpose in a wrong direction as would serve to cure her were it rightly ordered.

Emotion is commonly excessive in itself, and also in its expression. The patient is hurried from one extreme to the other with almost ludicrous rapidity; and often she walks, as it were, constantly upon that narrow line where tears and laughter meet. Laughter and sobbing not only alternate, but coexist; and often without any obvious and sufficient reason for either. There is sometimes listless indifference to everything of ordinary interest; sometimes absorption in some trivial object; often great restlessness and impatience, with extreme irritability of temper on any attempt being made at control, or any suggestion being offered of change.

These mental and emotional conditions are liable to much variation. Sometimes the patient exhibits them for a day or two, and then becomes "like an ordinary mortal;" sometimes they are persistent, and vary only in the degree of their intensity.

Sensorial Condition.—An exaltation of sensibility generally, may be
HYSTERIA. 313

the earliest, and sometimes the only sign of the hysterical condition. It may, and more commonly does, exist in association with other symptoms, or in the intervals of their recurrence; but sensibility may be altered in several distinct directions; there may be increased, painful, perverted, or diminished sensation, or there may be absolute though partial anaesthesia.

Hyperesthesia is very commonly confounded—nominally and perhaps theoretically—with painful sensibility or sensation, from which, however, it is quite distinct. The hysterical patient often exhibits true hyperesthesia; she does actually see, hear, smell, and taste what would not be perceptible to those in health, and to herself at other times. The exaggeration of hearing power is that which is the most frequently observed; hysterical girls do sometimes seem to "hear through stone walls;" they detect the minutest changes in odour or in taste, and exhibit an exalted keenness of sight. Their sense of touch is also sometimes preternaturally acute.

Painful sensation, or dysæsthesia, is almost universally present. One patient cannot bear the light, another is distracted by the slightest sound, to a third all ordinary odours are intolerable, and to others certain tastes, or the contact of sundry innocent articles of clothing are most highly objectionable. It is to be observed that the direction of attention to these always makes the painful sensations much more intense; the mere fact of asking a question about them may sometimes develop them. A middle-aged hysterical woman, whom I saw in hospital a few days ago, had been lying for weeks with her hand before her eyes "to keep out the light" of a dull London sky. Bringing a candle before her—the room being so dark from an accidental fog that I could not see the pupils—she shuddered, knitted her brows, and held both hands between her and its feeble light. There was no undue contraction of the pupils, and when her mind was distracted to the condition of her front teeth—the light being still close to her eyes—the brows were relaxed, the hands removed, and there was no expression whatever of uneasiness. This is but one example of a large class of dysæsthesiae which may be commonly observed in the hysterical.

A lady to whom I was speaking lately, in a tone by no means loud, exclaimed in a voice much noisier than mine, and putting her hands to her ears at the time, "Not so loud—not so loud;" but, a moment afterwards, she stirred the fire so vehemently, and made so much noise in the process that it was positively annoying to myself, and this without appearing to give herself the least uncomfortable sensation. Sometimes there is obvious and distinct painfulness of sensation upon impressions of ordinary intensity, and this may be limited to one or another organ. Most commonly, however, the pain is not necessarily associated with the impression, is of variable kind and locality, and intermittent in its form.

Besides these alterations of sensibility, hysterical patients constantly complain of "pain," more or less spontaneous in its development.
Such pain, wherever it may be situated, usually requires several strong adjectives for its description, and the account given of it is sometimes tediously minute. I have heard one hysterical lady enumerate and detail nine different kinds of pain in her chest! Of these some were bearable, some “intolerable,” others “agonising;” and four or five of them usually appeared together, and were present at the moment of description, and yet the face was calm, and simply conveyed the expression of interest in the description.

The localities of pain are very numerous, but some are much more frequently complained of than are others. The favourite haunts of hysterical pain are the top of the head, the left mammary region, the hypogastric, and the sacral. Sometimes the coccyx, and often one of the joints of the limbs is fixed upon; but I have rarely observed any definite pain in the reproductive organs. When one of the joints is painful, and there is much tenderness of the affected part, it will commonly be found that passive movements or even succussion of the limb may be borne without complaint, whereas even gentle pressure of the skin is described as “agonising in the extreme.”

There are other sensations of which much is heard that do not fall into any of the foregoing categories. The processes of ordinary life, which in health are unfelt, are sensible, and sometimes painfully so, to the hysterical patient. She feels the want of breath, the action of the heart, the intestinal movements, the processes of micturition and defecation, and even those of sexual intercourse to an exaggerated degree, and in a distressing manner. She feels “short of breath,” although there is no actual acceleration of the respiratory movements; “palpitation,” although the action of the heart is normal; rolling and rumbling movements when such are not perceptible to the physician; and distress or difficulty in relieving either the bladder or the rectum when there is no physical disturbance of such processes. Sexual intercourse is sometimes quite impossible from some morbid sensitiveness of the vulva or spasmodic action of the sphincter vaginae, neither of which can be detected on examination by the medical attendant.

There is further, the sensation termed “globus hystericus,” which is often, but by no means universally present. It is not always of the same character. Sometimes it is the feeling of a “great lump” in the hypogastric region, rising, through the epigastrium and chest, to the throat; but this is, so far as I have seen, extremely rare; and is more frequently met with in books than in practice. The commonest form of distress is that of a ball, or lump in the throat; a something which the patient cannot swallow, and which she feels will “choke” her. Anything round the neck is intolerable; she feels as if “something were tight there,” although there may be nothing present in the form of dress; she makes constant attempts to swallow, but the “lump will not move;” and these discomforts are exaggerated by sobbing efforts which very frequently attend them. Sometimes the patient puts her finger in her throat to cause vomiting, that she may “bring it up;” sometimes she drinks largely to “push it down;” but in spite of both
classes of effort the lump remains. Children when about to cry
know what the feeling is, and probably it is of the same nature in
the adult.

Diminished sensibility, and even actual anaesthesia of certain
localities, may also be found. Anaesthesia may exist over a large
portion of the surface of the body, and may extend to the deeper
tissues, to the muscles, and even to the nerves of special sense. It
most commonly follows an hysterical paroxysm, but it may be met
with when no such seizure has taken place. Commonly it is limited
to certain parts, such as the back of the hand or foot, but it may be
found along the course of one or more intercostal nerves, and in the
mucous membrane of the nose or mouth. It is a rare event in any
locality, but it has existed in several cases that I have seen in the
mucous membrane of the vulva and vagina; the anaesthesia in these
instances having been absolute, and that in highly hysterical, married
women, who had borne and were still bearing children. Probably,
aesthesia is the cause of occasional retention of the urine and of
the faces in hysterical patients, as either bladder or rectum may be
found sometimes enormously distended without the patient being
aware of any other discomfort than that occasioned by the swelling.

Motorial Condition.—In health there are different kinds of move-
ments which the muscular system exhibits; some are voluntary, others
depend upon idea, a third group upon emotion, a fourth upon sensation,
and a fifth upon impressions which are not felt. There is, moreover, a
certain relation between these which is characteristic of health, but
either of them may be so altered as to disturb the balance of well-
being, and constitute or exhibit either derangement or disease. In
Hysteria the normal relation is perverted, and there is an excess of the
involuntary motility, and a diminution of the volitional: the former
overrides the latter; and not only so, but the particular elements of
the former display their powers in an altered ratio; sensational move-
ments are not in due relation to emotional, nor are the latter to those
of idea. Generally speaking, the lower acquires the ascendancy, and
exhibits the most marked phenomena.

Involuntary muscular activity may be increased in regard of either
the readiness with which it is called into exercise, or the force and
persistence of its display. If these involuntary movements be placed
in the following order,—ideational, emotional, sensational, reflective,
and organic,—it will be found generally true that the increased
readiness of action is found at its maximum in the first, whereas
augmented force and persistence of action are observed most distinctly
in the last; and that the two kinds of alteration diminish in passing
from either one of these extremes towards the other.

Voluntary movements are sluggish, the patient often lying about on
sofas, or in bed, and saying that she is quite incapable of doing this or
that. Irrational movements are in excess; and, under the influence

* See article, Muscular Anaesthesia.
of morbid "notions," gestures may be assumed, and sundry physical efforts performed which transcend the powers of health. All the emotional movements are exaggerated; the individual laughs, cries, and makes grimaces of the most distressing kind, and manages often to do that which she could not do under ordinary circumstances.

Sensational movements are in excess, the brows are knit, and the eyelids contracted upon the approach of light; there is starting and tremor upon the occurrence of any sudden sound or jar; there is violent spasm upon the production of any pain; and this often without any real exaggeration of sensibility. Reflex motility is greatly increased and perverted, so that spasms arise from "irritations" which in health would be passed by unnoticed; and numberless movements, of momentary duration and varied locality, occur in relation to impressions which are quite inadequate to produce them in the normal state. Other muscular actions, tonic or persistent, exist in various parts of the body, which differ from the reflex in the fact of their permanence, and must be referred to some induced change in the nervous centres. Of these, cramps, and long-continued spasms in the limbs or elsewhere, afford the most frequent examples. These tonic spasms are not confined to the muscles of the limbs, they may affect the pharynx, the oesophagus, the stomach, or the intestines; causing difficulty of swallowing, vomiting movements, strange noises, eructations, hiccup, borborygm, and griping pains.

But besides the alterations mentioned, there is another kind, which is less common, but of more serious character, viz. paralysis. Loss of power usually occurs as the sequel of an hysteric paroxysm, but it may sometimes take place spontaneously.

M. Landouzy* states that in 47 cases of hysteric paralysis, the distribution of the symptoms was as follows:

<table>
<thead>
<tr>
<th>Symptom</th>
<th>Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>General paralysis of motion and sensation</td>
<td>3</td>
</tr>
<tr>
<td>of sensation</td>
<td>2</td>
</tr>
<tr>
<td>Complete left hemiplegia</td>
<td>8</td>
</tr>
<tr>
<td>Complete hemiplegia, side being doubtful</td>
<td>6</td>
</tr>
<tr>
<td>Paraplegia</td>
<td>9</td>
</tr>
<tr>
<td>Partial paralysis</td>
<td>19</td>
</tr>
</tbody>
</table>

Usually only one extremity is involved, sometimes only a part of the limb; but in many instances there may be what is roughly termed "hemiplegia." In the latter case the face and tongue are rarely affected, and the paralysis is incomplete, and the motion of the partly paralysed leg is not like that of an ordinarily hemiplegic individual. Dr. Todd says that the patient "drags the palsied limb after her, as if it were a piece of inanimate matter, and uses no act of circumduction, nor effort of any kind to lift it from the ground; the foot sweeps the ground as she walks."† This is true of many cases, and there is a yet further condition which may be noticed, viz. the absence of any special paralysis of the extensor

* Traité complet de l'Hystérie, p. 106.
† Clinical Lectures, p. 620.
muscles of the toes. If an ordinary hemiplegic patient be made to walk, it is seen that on attempting to raise the foot from the ground the toes droop and the leg is circumducted; but the hysterie patient does what the healthy person cannot help doing; when making the attempt to walk, she causes an elevation of the great toe at the time of endeavouring to move the foot forwards. The paralytic patient looks at his feet, the hysterie patient looks at her observers. The electric irritability persists in the palsied limb, and its nutrition does not become affected; but there is sometimes diminished sensibility to the electric current, it is at other times normal, and in some cases notably increased. Paraplegia is a form of malady sometimes witnessed, and patients suffering in such manner may keep their beds, or leave them only to exhibit a most curious mode of progression, or a series of falls which are quite unlike those arising from organic lesion of the spinal cord. At this moment I have under my care two cases of hysterical paraplegia, in which the symptoms are almost precisely similar. The limbs are well nourished, there is perfect electric contractility, and sensibility; the patients when lying in bed can elevate their limbs, separately or together, to any height that is required; they can move all the toes, and cutaneous sensibility is intact: but if they attempt to walk, their legs appear to be no stronger than pieces of wet paper, and they tumble down and bruise themselves in various quarters. What, however, is peculiar in the attempt at walking is this, that no amount of help, such as a strong arm on either side, prevents the staggering and falling, but the patients tumble down to within a few inches of the ground, and then recover themselves without help. An ataxic patient would walk, comparatively speaking, well with such assistance; a really paraplegic patient could not so recover the upright position. Where paraplegia has been hysterical, I have not found loss of power over the expulsors or the sphincters of either rectum or bladder; although it often happens that the latter exists without the former. General paralysis is extremely rare, and is only imperfect in degree.

The General symptoms in Hysteria, or those outside the nervous system, are not distinctive in their character. Usually the patient is not in robust health; there is some pallor, and failure of nutrition, or there may be a great tendency to deposit of adipose tissue. Sometimes there is a condition of habitual ill-health, or delicacy; digestion is impaired, or the uterine functions are irregular, or there is some constant, but more or less indefinite grievance in the head, thorax, or abdomen. On the other hand, there are many cases of Hysteria in which the general health is good; the patient eats, drinks, sleeps, feels, and is “well.” Numbers complain of nausea, and eructations, or vomiting; but in many cases these symptoms have been entirely due to errors, and even absurdities of diet, and in not a few to excess of stimulants. It is by no means rare for hysterical people to “take to drinking.” Alcohol
relieves them for a time, is often recommended by medical advisers, the patients know its power to diminish their passing discomforts, and push, beyond all reasonable bounds, their recourse to its aid. Flatulence and borborygmi of the intestines, are common enough; and so are palpitation of the heart, syncopeal feelings, and dyspnoea; the latter, however, without any notable change in the ratio of respiration to pulse. Large quantities of pale, limpid urine, of low specific gravity, are passed; but this is also true of epilepsy and of many other diseases of the nervous system. With regard to affections of the generative organs, there is great discrepancy of opinion. Landouzy states that in twenty-six, of twenty-seven cases, there is some abnormal condition;* and, further, that of sixty-seven cases of Hysteria, the symptoms coincided with material alterations of the generative apparatus in fifty-eight; and that in nineteen cases the Hysteria was cured after the removal of the genital affection;† but it is, so far as my experience extends, the exception and not the rule to find any definite malady, or indeed definite complaint in this direction; while in a vast number of cases there has been absolute health in all particulars relating to the reproductive organs.‡

When men have presented hysterical symptoms there have always been, in my practice, considerable deterioration of the general health, an impaired nutrition, and a feeble circulation, with exhausted brain.

(b) Paroxysmal Symptoms.—The attacks of hysteric convulsion do not pass through stages that can be defined, like those of epilepsy, to which they sometimes bear a rude resemblance. They differ widely in degree of intensity, but have a general similitude inter se, and can rarely be mistaken in either their slighter or severer form. When slight they are but an exaggeration of the interparoxysmal state; when severe, they have been confounded with certain grave diseases.

The following may be regarded as the description of a severe attack. A patient is talking vehemently, often unreasonably, and is agitated in manner; she is crying or laughing, or both, and perhaps apologizing for, or lamenting her weakness; friends are either scolding or condoling, and sometimes there is a combination of both modes of domestic treatment; some real or imaginary grievance is uppermost in the mind and the conversation, and it is not “met” or removed by the endeavours of the friends. Suddenly the patient gives a scream, or makes a spluttering noise, appears to lose voluntary power and self-control; she falls down with snorting breathing, and a quasi-tonic contraction of the muscles of the extremities and the trunk. She makes hideous grimaces and outrageous noises, throws her limbs about in a disorderly manner; utters incoherent sentences, adopts his-

* Traité, p. 171.
‡ Niemeyer says, “Unter den Krankheiten des Uterus sind es ausser dem Infarct namentlich die Geschwüre des Muttermundes und vor Allem die Knickungen der Gebärmutter, welche am Häufigsten zu H. führen, während bei bosartigen Neubildungen und bei destruktiven Prozessen hysterische Zufälle weit seltener sind.”—(Handbuch, 2er Band, p. 356.)
tronic attitudes; complains of her throat and stomach, and breathing; appears exhausted, or faint, and sometimes stupified; occasionally she seems to lose her consciousness, and then, after a fit of "crying" to be "herself again." The whole paroxysm may last for a few moments only, but more commonly it is of much longer duration; a number of absurd gesticulations and irregular convulsive movements lasting from a few minutes to three or four hours, after which the patient seems worn out, and falls asleep.

These points may be observed during the attack:—There is rarely absolute, or sudden loss of consciousness; the patient does not fall in such manner as to hurt herself, or tear her clothes; there is somebody near who shall see the phenomenon; hysteric paroxysms do not occur during sleep, or when the patient is alone; there is something artistic in the mode of their approach—the hysteric patient gathers her robe around her, and falls gracefully; she appears to the casual observer to be unconscious, but there is not real or absolute loss of sense or of perception; there is not the hideous distortion of feature observed in epilepsy, nor is there the dilatation of the pupil; the eyelids may quiver, and the eyeballs may be turned up; but there is no divergent strabismus, nor is there the wide-open eye. Examined carefully, the physician may observe that the patient not only sees, but looks; the eyes are often definitely turned towards objects or persons standing near, and then rolled up again towards the forehead; there is no bitten tongue, although there may be much foaming, and spluttering with the mouth; the breathing is tumultuous and noisy, but there is no such absolute arrest of respiration as to cause asphyxia; and the irregular movements and noises that accompany the laboured breathing may often be seen to be occasioned by the lips; the attacks last for an indefinite time, are followed by much apparent exhaustion, but not by real stupor.

Wherever the attacks pass beyond the description here given, it is probable that something more than mere Hysteria exists, and that the case borders upon the much more severe ailment known as epilepsy. In a few patients the two diseases co-exist, and then the attacks bear some of the characters common to the two elements; but in the vast majority of cases it is comparatively easy to distinguish between them.

Mr. R. B. Carter, in an interesting book,* has described the hysteric paroxysm under three phases, giving to them the terms "primary," "secondary," and "tertiary;" implying that in the first instance the attack is quite involuntary, and is the product of violent emotion; that in the second, it is reproduced by association of ideas; and that in the third it is deliberately "got up" by the patient. There does not, however, appear to me to be sufficient reason for adopting these phrases, as I am sure that in many instances all that can be said of any of the tertiary paroxysms may be affirmed with equal accuracy of the very first attack.

* On the Pathology and Treatment of Hysteria, p. 43.
A SYSTEM OF MEDICINE.

Hysterical Mania sometimes appears after an attack, and its features resolve themselves into an exaggeration of the condition already described as the "hysteric state." The patient is unmanageable, sometimes mischievous, and very often highly abusive; but generally is merely loquacious, unreasonable, and demonstrative in regard of emotion; and the attack speedily subsides under judicious treatment. It, however, exhibits a great tendency to recur; and hysterical patients sometimes become, for a time, maniacal without going through a paroxysm of convulsion.

Hypochondriacal symptoms are met with, and are by no means rare, in cases of Hysteria; but it is quite easy to separate the two diseases.

Pathology.—Anatomical investigation has failed to show the presence of any organic lesion which is either so constant or so prevalent in Hysteria, that it may be justly regarded as its cause. Pathological examination has been equally unsuccessful in its attempts to explain the disease by a reference to the disturbed function of any one set of organs. It is common to find some derangement of the digestive, the assimilative, or of the reproductive systems; but these may exist without hysteria; and, vice versa, that disease may be present when those bodily functions are healthily performed. There is, however, one thing common to all cases of Hysteria, and that is a perturbed condition of the nervous system. The essential character of this morbid state is an exaggeration of involuntary motility, and a diminution of the power of the will; the emotional, sensational, and reflex movements are in excess, while the voluntary are defective. The outcome of such a condition is seen in the mode of life of the hysterical patient. The will is determined by anything rather than by judgment, while ideas, feelings, and fancies exert an undue influence. Sensations are often morbidly acute, are uncorrected by any careful discrimination, and thus they increase the evil. Reflex movements, which in health are under some control, are not only exaggerated in their individual intensity, as a part of the hysterical state, but, from the weakness of volition, are allowed to run such riot that they pass beyond all bounds of healthy influence.

This is, I believe, the true pathology of Hysteria, a disease which is more closely associated with affections of the mind than with those of the generative organs, although it is well known that the latter may and do exert a marked influence upon the former.

The hysterical state is essentially one of mental perturbation; and it is brought into existence, if not inherited, by those conditions which are the most active in producing disorder of the mind; in the male sex by worry, anxiety, over-work, late hours, and dissipation; in the female sex by vexatious emotions, want of sympathy or success, disappointed and concealed affection, want of occupation, fear, and morbid conditions, or supposed morbid conditions of the reproductive system. The latter are sometimes the coincidents, but I believe much more commonly the effects of Hysteria than its cause. Their
relation is by no means constant in existence, and is most variable in kind.

It would appear that the nutrition of the whole nervous system is changed, but that the change is of such kind that it passes beyond our power of recognition, except in its physiological or pathological effects. We cannot see degeneration of tissue here, or too rapid a metamorphosis there; but we can witness the effects of such morbid processes, in movement, in secretion, and nutrition, and we can observe some of the ulterior results of such changes, in emotion, and sensation.

The influences exerted by emotion upon secretion and nutrition have been well shown, in their relation to Hysteria, by Mr. Carter,* and the inter-relations of physical, mental, and moral life have been very ably treated by Mr. Hovell in a more recent publication;† but the primary fact in that condition which we term Hysteria, would seem to lie behind all that is referred to in these considerations, and to consist in that special morbid change of the nervous centres, which either gives to emotion an undue influence, or removes the limitations of its action. There are divers links in the chain of causes and effects, but there is one link at which, in fixing upon the pathology of Hysteria, we must stop and say—all behind this is cause, all beyond it is symptom or effect; here is the one-point which determines the hysterical result. Up to this link we find the causes of chorea, of epilepsy, and of insanity, together with and identical with those of Hysteria; beyond it we find neither chorea, epilepsy, nor insanity, but what we term Hysteria; in that link, therefore, we must seek for and find, if we can, the essential fact of the disease. I do not say that we have found it; still we are much nearer its discovery than we were fifty years ago: but I think it better to state, in general terms, wherein this morbid condition lies, than to lose sight of that point, by regarding some outlying facts, and attaching undue importance to certain frequent lines of apparent causation and effect. There is nothing to prove that the vasomotor, or sympathetic system of nerve-fibres is primarily at fault; on the contrary, it often appears that the secretions and the general nutrition are late in suffering; and that the earliest departure from health is to be found in the disturbed balance of mental and emotional operations. If it be held that every change in every organ, and every function is, more or less directly, determined by a change in the vasomotor nerves, Hysteria may be

† Medicine and Psychology, p. 56, &c. The gist of Mr. Hovell’s argument lies in the following sentence: “The nutrition of the body is not affected, mental power is not impaired, although it may be suspended, innervation is deranged, for the generation of nerve power is feeble, and its distribution is irregular; but it is the sympathetic, the vasomotor system, the moral power that is at fault; either from exhaustion of the physical strength or the sensori-motor centres, or because, perhaps most frequently, the purposes of life are in some respect disappointed, and the parésis of disappointment not only saps the strength, but at the same time that it brings low the nervous system, also renders it peculiarly liable to irritable excitability from opposing and aggravating causes.”—P. 70, op. cit.
driven theoretically into this "sympathetic" corner; but, when it is
made to go there, it will find itself in company with almost every
ill to which flesh is heir—with tubercle and corns, with cancer and
ataxy. If the "vasomotor system" furnishes the agency by which
all departures from health find their expression, we have yet to dis-
cover the nature and cause of those special changes in its action which
lead to these particular results.

Every one knows that, in health, there are numberless processes
which are quite familiar to the mind, but which appear very strange
when described in technical language. A physiological or pathological
discovery is sometimes nothing more than the translation into
scientific terms of a "well-known saw;" and what may now be said
upon the pathology of Hystera is little more than such translation.
Slight emotional excitement, such as shyness, trifling vexation, or
moderate pleasure, may flush the face, quiver the lip, and make the
breathing "panting;" strong emotion, such as terror, intense anger,
or disgust, may blanch the cheek, fix the jaw, parch the mouth, and
hold the breath. Moderate distress may "find relief in tears;" but
when grief is deepest the eyes are dry. The postures of the various
emotions are known, and have been studies for the artist in marble
or on canvas, and for the actor on the stage. If we express this
physiologically, we say that emotions lead through certain nerve-
tracks to the contraction or elongation of some muscular fibres: that
the vessels are dilated in the one instance, so that more blood than
usual passes through the organs; and are diminished in the other, so
that the circulation is arrested; in the former, occasioning an excess
of secretion, in the latter, a defect; that the muscles are spasmo-
dically fixed in one condition, and in another are relaxed; but what
we want to know is the primary fact leading to such changes, when
they are unusual in degree or persistence, and morbid in kind.

Some individuals, we say, have more "control over themselves," or
more "presence of mind," than others; that A never shows what he
feels, while B never hides, and never can hide, anything; and if we
translate this into technical phraseology, it is but to say that the one
is of "phlegmatic," and the other of "nervous temperament;" that A
is astolid, resolute individual, and that! B is somewhat "hysteric;"
but here again we do but throw the question one step backward.

There is an old proverb to the effect that "it is the last straw that
breaks the camel's back;" and if we put this into other terms it often
means but this—that an individual has for a long time gone on bear-
ing what was too much to bear healthily, that he has struggled against
it, and by forced effort has made everything appear quite tolerable or
even easy; but at last he "breaks down" from some "shock," and
then all the "wear and tear" comes out, and friends see that he
had done or borne far too much before. Sometimes what is held to be
"shock" is a mere trifle compared with the rough handling that had been
previously endured without complaint; it is simply because it, a mere
"straw," fell upon the already over-burdened soul that the great crash
came, and that then—all power of resistance being gone, the "back broken," as it were—the brave sufferer was prostrate, crushed, gave way, and the pent-up tide, he had kept back so sternly, broke through destructively.

In some there is weakness at the outset, congenital, or acquired; in others there is weakness, but it is induced by long patience, vexation, care, or trouble, that have at last done their work, and a work which it may take years to undo. But here, again, we have yet to learn why, out of a hundred individuals similarly exposed, one becomes hysterical, another epileptic, and a third maniacal.

If we refer to the etiology of Hysteria, we shall see that all the facts point in one direction; if we look to the symptoms we shall see that they are partially explained. In the female sex, at certain ages, and under certain conditions, Hysteria is most common, for it is but an exaggeration of that which constitutes the normal characteristics of that sex; in the male sex it is met with when circumstances have gradually converted males into the condition of the other sex; i.e. when emotions have been so played upon that they have, at last, broken through the force of resistance, which held out for a long time bravely, but at length gave way.

The essential fact of Hysteria, then, is the distorted balance between voluntary and involuntary power; volition is defective; emotional, sensational, and reflex activity are in excess; and this distortion may be brought about by the many and divers circumstances of age, sex, position, employment, and the like which have been enumerated in the section on etiology; but the precise nature of the change which is the efficient cause of such distortion—i.e. the primary physical fact in the pathology of Hysteria—has yet to be discovered.

Diagnosis.—If the symptoms already described be borne in mind, and the history of each case be carefully considered, there is not much difficulty in the diagnosis. A physician called in on an emergency may have, however, to distinguish Hysteria from several diseases which it simulates.

From Epilepsy it may be separated by negative characters. There is neither the suddenness of attack, the absolute loss of consciousness, the dilated pupils, the complete asphyxia, the bitten tongue, nor the reckless injury of either the person or the clothes. The patient "looks about," the attack lasts longer, there is much sobbing and crying, much exhaustion, but no perfect stupor. The interparoxysmal state of the hysterical patient exhibits features not met with in epilepsy, and vice versa.

From various inflammatory affections, such as Peritonitis, Laryngitis, and Arthritis, hysterical symptoms may be distinguished by a careful use of the thermometer, which fails to show any rise of temperature. Again, the tenderness of parts complained of may be seen to be ideal rather than real, and to bear relation to the skin quite as much as, and often more obviously than, to the deeper tissues. When there
is loss of voice, this has the characters already described; there is no attempt made to whisper loudly; the failure is evidently not in the apparatus of voice, as a mechanical production, but in the will to put that machinery into play. A laryngoscopic examination will show that the throat is healthy, or is simply relaxed—the vocal cords being widely separated, and slight effort being made for their approximation. The pulse-respiration ratio will further show that although the breathing may be tumultuous, there is no real dyspnoea. Phantom tumours may be removed by the inhalation of chloroform, while palpation and percussion usually reveal the nature of their constituents.

Organic diseases of the nervous centres, which are sometimes simulated by hysteric paralyses and anaesthesiae, may be excluded by the conditions already described, when detailing, in the section on symptoms, the mode of their development. Usually the phenomena presented are inconsistent with the idea of any definite disease of either the cerebrum or the spine; the paralyses are imperfect in development, vague in their distribution, and changing in their locality; they are not accompanied by the alterations of nutrition, or of electric contractility or sensibility which are proper to other affections; and the history of the case will usually reveal their true nature. The walk in hysteric paralysis has already been described (p. 316); but it is further to be observed that the patient does not look at her feet, as those who are ataxic do, but looks round about her to observe the effect of her performance. The ataxic or paraplegic patient tries to walk; the hysteric girl tries to show that she cannot use her limbs: if the former forgets himself, he falls; if the latter forgets herself, she walks.

 Neuralgia, when of hysteric origin, has not the real intensity of the genuine disease, as may be proved by withdrawal of attention. There is also an absence of those "painful spots" which are present when Hystera does not complicate the case. The distribution of pain described by hysteric patients is, moreover, often so wide of all relation to anatomy and physiology, that its true nature may be recognised.

Prognosis.—When once established, Hystera is very difficult to cure, and this is true under all the conditions of causation. The most difficult cases are those in which it is but an exaggeration of a constitutional defect, inasmuch as it is impossible to cure the malady without changing the individual, and this is by no means an easy task. If the hysteric habit be natural, or have become a "second nature" by long existence, the prognosis is pro tanto bad: if it be something quite unlike "the former self," or if it have been only recently developed, there is much room for hope. If the cause exist in the patient, i.e. in the essential features of the individual character, comparatively little can be done; if it lie in external circumstances, much may be done, provided that those circumstances can be changed. If there be definite organic disease, and this be of such character that
it is amenable to treatment, prognosis is so far favourable; but if there be no such disease, and \textit{a fortiori} if the general health be good, the prognosis is unfavourable.

Hysteric symptoms, such as paralysis, aphonia, and the like, are often easily removed when they are of recent origin; but when they have existed for many months, the prognosis with regard to them is unfavourable. It is not, however, hopeless; for in some cases, of even many years’ duration, there has been amendment, and—but more rarely—cure.

The prognosis in Hysteria depends, therefore, mainly upon these two things—the nature of the “cause,” and the freedom with which treatment may be employed. No human being can cure, the physician can do but little for, one who is born hysteric; \textit{i.e.} for one whose disease is but an exaggeration, and sometimes only a slight exaggeration, of her habitual, constitutional state. Education might have accomplished much in childhood, but often when the physician is called in, the grooves of life are worn so deeply that he cannot change them, and all that is possible is to soften their sharp edges, or to retard the movement which he can neither stop nor guide. In such cases the prognosis is unfavourable. When Hysteria is an accident, is unlike the earlier promise of the individual, or when it is brought about by long, and at last unendurable, pressure from without, then there is much room for hope. When the treatment of the hysteric patient is cramped by the anxieties of friends—limited, in this direction and in that, by frightened, too sympathetic, or unwise relatives—the prognosis is unfavourable; but when the circumstances are such that the physician can control them all, much hope may be entertained. Upon these points, rather than upon the special character of the symptoms, the prognosis turns. When Hysteria is a disease, and the physician has given to him a \textit{carte blanche} to treat it as he deems best, the patient may be cured: but when it is a constitutional peculiarity, and the physician is checked at every turn by anxious friends, the case is hopeless, and might as well be left alone.

In regard of all special symptoms, the prognosis is more favourable than it is in those diseases which Hysteria simulates; but even here the general principles just stated are the most trustworthy guides in our attempts to forecast the future.

\textbf{Treatment}.—The old copy-book maxim, “Prevention is better than cure,” expresses but a small portion of the truth in regard of the management of Hysteria: prevention might be easy; cure is often almost impossible. \textit{It is not within} the scope of this work to describe generally the processes of a healthy education, but some things that are special must be said with regard to prophylaxis.

Bearing in mind the pathology of the disease, it is highly important that its earliest indications should be recognised and combated. Where there is the tendency to Hysteria in early life, these things are necessary:—
1st. A strenuous effort to draw the person "out of himself," or "herself," and to develop the faculty of self-control. This should be done, not as an occasional or spasmodic effort, but as the business and prevailing arrangement of daily life; and while it is done, and in order that it may be done, the predisposed person should be unconscious of the process. A child who is "peculiar," disposed to be taciturn, loquacious, "excited," or unduly gay; or who is very readily "upset," and is "so sensitive," that parents and others are "afraid to tell her" this or that, "for fear that it should make her ill;"—one who is "impulsive," and disposed to find fault with herself without just ground; one who is "shy," and hides herself; one who is morose, and who thinks herself "misunderstood;" or one who is retiring, and shuts herself out from the sympathy she craves for;—should be carefully watched, tended, and unconsciously guided away from self, and into some line of feeling, thought, and action, which may interest the mind without fatiguing the body. The worst thing that can be done is that which makes the patient know and feel that she is thought to be "peculiar." Sometimes such treatment is gratifying to her, and she likes it—it is easy, and it "seems kind" to give it—but it is radically wrong. Anything that looks like harshness, rigid discipline with a view to improvement, or want of sympathy from want of "understanding her feelings," is shrunk from, or resented by, the patient, and is worse than useless. At the same time, all exhibitions of a want of self-control should be checked, and much of this kind may be done in the nursery, and long before Hysteria is dreamt of. Kindness, firmness, and obvious recognition of "tender points," with judicious, sympathetic, and wise regard to them, may do much to avoid future evil; and sometimes the qualities of mind which will produce such treatment may be met with in a parent, a sister, or a governess. The physician should guide, in little details of daily life, those who have the management of such a child. The object is to make her feel that she is understood and cared for; and the best mode of attaining this object is often indirect in its operation. The mind and the heart should be engaged in some healthy pursuit; interest should be awakened, and exercised in anything—it matters not what—outside the individual; self should be lost sight of, and life made useful.

2nd. The bodily health should be most carefully regarded, and this without any admission or appearance of anxiety on the part of others. The points that require attention are the following:—(a) Diet, which should be sufficient, wholesome, and easy of digestion, avoiding too long an interval between meals, and observing an especial regularity in the times at which they are taken. (b) Rest. The hours of sleep should be long, and those of rest or lying down not too long. Hysteric girls, or those who are disposed to become such, are in the habit of reading at night and of lying in bed in the morning. Such habits should be broken,—not roughly, for the sake of breaking them, and of "doing something disagreeable," but—by supplying a reason and a motive for
HYSTERIA.

327

a different mode of life. (c) Exercise should be taken regularly, and in the open air, as much as possible without fatigue; and here, again, the exercise should have some other apparent object than a mere piece of tedious hygiene. (d) Recreation should be ample and merry; but all such things as precocious or preternatural excitements should be avoided. (e) Study should be systematic and disciplinary, but varied and interesting, and made to subserve some purpose which lies, obviously, outside of mere personal accomplishment or pleasure. (f) The various functions of secretion, excretion, and (if they have commenced) of menstruation, should be regulated; and this, again, should be done, as far as possible, without any particular notice being taken of the fact that they may be unhealthy.

3rd. Some motive or purpose should be supplied which may give force, persistence, unity, and success to the endeavours of the patient. This is sometimes very difficult to manage; but it is less difficult in early life and in predisposed persons than it is in those who are older and have already shown definite symptoms of the malady. Still, much may be done by those who have a little ingenuity in detecting character, and a great deal of perseverance and determination in carrying out their wishes. The patient should be led to feel that the object is in itself desirable; she should never think that it is suggested for her own treatment or benefit. If she is urged on the former ground, she may do much; if on the latter, she fails entirely. The hysteric patient is often most thankful for and happy in the idea that she is doing good to others, and she will take great pains to make her efforts successful and pleasing; but she hates the notion of doing anything of such kind as a mere means of self-cure, thinks that the doctor who recommends them is grossly ignorant of her real wants, and that the friends who urge her onwards are singularly stupid or unkind in their advice. To "make an effort," simply because told to do so for her own sake, is sheerly detestable to the hysteric patient, and is sometimes as impossible as it is distasteful; but to exert herself, almost unconsciously, because a motive is supplied, is scarcely felt to be an effort. The patient does what she is herself surprised and pleased with, and derives great benefit from the process.

When the symptoms of Hysteria are developed, the treatment should be conducted upon the principles already laid down with regard to prevention. There is, so far as I know, not one single drug which exerts any specific action on the disease; but there are many medicines which may be used with advantage for the relief of associated disorders. These do not require any special notice here, further than to say that if the patient be anemic, iron is useful; if deficient in general nervous tone, quinine, strychnia, and vegetable bitters may do good; if there be indigestion with much flatulence, bismuth, charcoal, and alkalies, or mineral acids with light bitter infusions, may give relief; if there be constipation, mild aperients may overcome the difficulty; if there be menstrual derangements, they should be treated upon general principles.
The whole list of anti-hysteric remedies—such as musk, castor, valerian, assafetida, and the like—appear to have this one property in common, that they do no good, and delay the real treatment of the case, which is not one of "nauseous gums," but of mental, moral, and social management.

Painstaking appreciation of the patient's own feelings; determinate assurance that the disease is a real thing, and no idle fancy; strenuous effort to help the patient in weakness, and to set her right when wrong; fertility of resource in little things; a cheerful but not boastful, a sympathetic and calm, but neither condoling nor anxious, manner; and a strong will, with patient work and tact, may do very much, and may often cure. But the physician should see that he manages his patient, and that all that he has attempted to effect is not undone by frightened relatives or anxious friends.

There are some drugs which are useful under special circumstances; and these are opium, or morphia, where there is loss of sleep, or persistent pain; and the diffusible stimulants, where there is a great tendency to recurrent spasm. Morphia may be administered most effectually, for the relief of pain, by hypodermic injection: it may be given by the mouth, with light food, when there is want of sleep. Chloric ether, ammonia, and musk, often relieve the tendency to spasm; and in some cases Indian hemp has proved of service when other medicines have failed: in the large majority of cases, however, I have found Indian hemp of but little use. Assafetida, in doses of thirty grains, three or four times daily, is of service in some cases. Bromide of potassium has appeared to me to be singularly useless in Hysteria, failing to relieve either the attacks or the symptoms which exist between the periods of their recurrence.

The attacks of hysteric convulsion may be arrested by a plan suggested by Dr. Hare—viz. that of forcibly preventing the patient from breathing, for a certain time, by holding the nose and mouth. The effect of such constraint is to make the patient, when allowed to do so, "draw a long breath," this vigorous inspiration being usually followed by a relaxation of all spasm, and a disappearance of the fit. Some attacks are of such short duration, that there is neither occasion nor time for this mode of treatment; but when they are prolonged, I have seen it notably useful.

Dashing cold water on the face and neck may sometimes succeed in doing imperfectly that which Dr. Hare's treatment accomplishes effectually; but even cold water is not always at hand, and when it is—in addition to its other inconveniences in regard of carpets and dress—it often fails to do any good.

A calm manner, the absence of all appearance of alarm, and of either scolding or distressing sympathy,—all of which things the apparently unconscious patient observes much more accurately than do her frightened friends,—will sometimes bring a fit to a speedy end.

A calm manner, the absence of all appearance of alarm, and of either scolding or distressing sympathy,—all of which things the apparently unconscious patient observes much more accurately than do her frightened friends,—will sometimes bring a fit to a speedy end.

Some special symptoms of Hysteria require special treatment. Aphonia may often be cured by electricity; and the mode of appli-
cution which has appeared to be the most useful is that of giving sparks to, or taking them from, the larynx. An ordinary plate or cylinder machine may be used for the purpose, and either the patient or the physician may be insulated, and the sparks taken from or given respectively by a brass knob. The interrupted current from a magneto-electric or volta-dynamic apparatus may be used so as to pass the shocks through the throat, or a shock may be administered from a charged Leyden phial. Under all these circumstances, the voice is sometimes instantaneously restored. But when Aphonia has been of very long duration, and such measures fail to affect it, good may be done by directly galvanising the vocal cords, in the manner proposed by Dr. Morell Mackenzie. Further, I have known a strip of blister round the throat recall the voice when all means of electrifying have failed.

Paralyses are treated very successfully by Faradisation, and by passive movements and frictions, employed by a well-instructed nurse. The electricity should be applied to the muscles affected, and also to the skin which covers them. I have, however, found no mode of treating hysterical paralyses comparable in efficiency with that of placing narrow strips of blister completely round the affected limbs. This method of treatment has succeeded perfectly and rapidly, after all other plans have failed.

Rigid Contractions may be relieved by the continuous galvanic current, but much more successfully by the inhalation of chloroform, and the adaptation of some apparatus to maintain extension when the effect of chloroform has subsided. Passive movements are also of much service in such cases. Drugs may be taken in almost poisonous doses without relieving tonic spasm.

The treatment of other symptoms must be conducted upon the general principles already laid down, and may be assisted by those local sedative measures to which allusion has been made.
MUSCULAR ANÄSTHESIA.

By J. Russell Reynolds, M.D. F.R.C.P.

Definition.—A loss of the feeling of muscular action, attended by irregularity, sluggishness, and diminished force of voluntary movement; but unattended by any necessary loss of cutaneous sensibility, or by distinct paralysis.

Nomenclature.—The property which is diminished or lost, in the affection above defined, has been described under different names, of which the following are the more important:—"the muscular sense;" "le sentiment d'activité musculaire;" "le sens d'activité musculaire;" "la conscience musculaire;" "le sens musculaire;" "le sens de la force;" "le sentiment du mouvement;" "der Muskelsinn."

Symptoms.—The essential features of this condition are the following:—awkwardness and clumsiness in performing certain voluntary movements, sometimes of the hand and arm, sometimes of the face. The patient tries to do what he wishes, or is told to do, and succeeds in the attempt by looking carefully at his limb, and helping it with one of the others which is unaffected; but if not paying great attention, or making any great effort, he fails to effect the movement, lets objects fall out of his hands, knocks his legs the one against the other, or in some other manner exhibits clumsiness and want of co-ordinating power. If placed in absolute darkness, or if the eyes are bandaged, he may be unable to execute any movement. The negative features are, that there may be no loss of cutaneous sensibility; the special senses may be intact; and there is no distinct paralysis.

Movements instituted in the affected parts are less vigorous than is natural; the limbs are somewhat inert, and often hang idly by the side or are carried by some mechanical contrivance; but they can be, by a strong effort, rendered almost as vigorous as in health, and the individual, after two or three awkward failures, may succeed in performing some complex act, provided that he thinks much about it and looks fixedly at what he is attempting to do.
If the muscles are pinched forcibly between the fingers, or if they are submitted to the electric current, they exhibit a diminution of sensibility. This has been well shown in a case lately under my care in University College Hospital; the patient did not know when the magneto-electric current was applied to the muscles of the right leg, although they could be seen to act quite vigorously. There was loss of cutaneous sensibility and of muscular power in the same limb, but electric irritability, although diminished, was preserved. As the voluntary power and the sensibility of the skin returned, some electric sensibility returned also, but it was notably deficient long after the electric contractility was almost normal; the patient being scarcely conscious of an amount of actual contraction of the muscles induced by electricity, which amount could not be tolerated for a moment in the muscles of the unaffected limb.

Without looking to see, the patient does not know the position of his limbs; and even when he has voluntarily assumed any attitude or position, he swerves from it if his attention be directed to some other object than his own limbs.

Minor degrees of this disturbance may often be observed in conjunction with definite but partial paralysis, in either a paraplegic or hemiplegic form. Such patients can only move their toes or fingers when they are looking at them; and they do not know, if their eyes are closed, whether they are moving their extremities or not, but, in perfect innocence, may ask the physician to inform them.

Commonly, Muscular Anaesthesia is seen in combination with other evidences of profound change in the nervous centres; but sometimes it exists, and that for a considerable time, alone. It may be, and often is, the precursor of paraplegia, and under such circumstances may be confounded with ataxy, spinal congestion, commencing myelitis, or softening of the cord.

The following case affords a fair illustration of the malady:—

A. B., female, at the age of 18 or 19 years, "caught cold" during menstruation, and soon afterwards felt "loss of power" in the legs and hands; she stumbled in walking, and found it very difficult to dress herself. The symptoms became slowly better, but occasionally returned; and three years after their commencement she married, and at the time of my seeing her, eighteen months after marriage, had a baby three months old.

She walked into my room leaning upon the arm of a friend, but she stumbled, and nearly fell down in doing so; her position in standing, when without support from another person or a table, was that of inclination forwards, and she rocked about from side to side, and antero-posteriorly: when she attempted to walk she occasionally reeled, and did this especially when engaged in conversation. If told to make an effort to walk in a straight line, she looked carefully at her feet and managed to do so without much deviation. When standing with her heels together she maintained steadiness of position so long as her hand was on the table, or she was paying attention to
her drill; but, in a moment, if her mind was distracted by conversa-
tion, she staggered, and caught at some object for support. She told
me that her hands were much better than they had been previously;
but that still they were "very odd." It was, as I observed, difficult,
and indeed impossible, for her to do sundry little things, such as
putting a pin into her dress or taking it out, fastening or unfastening
a button, without seeing either her fingers or the reflection of them
in the glass. She found it impossible, or very difficult, to play on the
pianoforte, and as she expressed it, she "could not fasten anything
she could not see." Objects fell out of her hands when she did not
look at them; when standing with support on both sides, but with
the eyes closed, she could not raise either foot from the ground,—the
sole of the foot seemed glued to the carpet. The cutaneous sensibility
was perfect; the electric contractility and sensibility were natural;
there was no failure of general health, no tenderness of spine, no
alteration in the special senses, no pain; and there were no symptoms
of hysteria. All that was lost in this case was the sense of muscular
condition and action.

CAUSES.—Nothing definite is known with regard to these, beyond
the frequent association of Anaesthesia Muscularis with hysteria.
I once saw a marked case of muscular and cutaneous anaesthesia
which had been induced by exposure to cold. The symptoms in this
instance were developed suddenly; but in other cases their commence-
ment has been insidious, and their progress slow; and it has been
impossible to assign any rational cause for their production. In
many they have followed a series of convulsions or other symptoms
of hysterical character.

DIAGNOSIS.—From paraplegia generally, whatever may be its cause,
muscular anaesthesia may be distinguished by the facts that power is
not lost, and that forcible movements may be determined, although
not directed with exactness. In ordinary paraplegia the awkwardness
of movement is due to and proportioned to the want of power; in
muscular anaesthesia there is no such relation. Moreover, the patient
exhibits none of the signs of interference with those functions of
the spinal centre which are speedily involved in all cases of para-
plegia depending upon changes in the nutrition of the cord. The
limbs do not waste, the skin undergoes no special alteration, the
urine is not altered, and sensation in other directions is unchanged.
From hemiplegia, indicative of those cerebral diseases which are
usually accompanied by paralysis of one side of the body, muscular
anaesthesia is separated by considerations similar to some of those
which have just been mentioned; but mainly by the absence of
conformity of the case to the known types of cerebral lesion, by free-
dom from intellectual change, and by the limited distribution of
the symptoms.
Locomotor ataxy resembles muscular anaesthesia in its most striking symptom, viz. want of co-ordinating power; and in many cases of the former there are symptoms of the latter. It was present, for example, in 28 of 50 cases analysed by Topinard,* but it was absent in 22 cases, and was but slightly marked in eight. The clinical history of locomotor ataxy is different.† There is not necessarily the special want which is the essential condition of muscular anaesthesia; and in the latter there is an absence of pain in the limbs, of implication of the genital organs, and of affections of the eyesight.

Hysterical patients often exhibit the phenomena of muscular anaesthesia; indeed it is one of the expressions of their malady; and the only point of interest to ascertain is the degree to which this condition, the hysteric, may account for all the symptoms. The general course of the case usually affords the information that is required; it would be unsafe to refer Anaesthesia Muscularis to hysteria, unless other symptoms of the latter disease were present; it would be unwise to suspect the existence of grave central lesion unless hysteria could be excluded.

Pathology.—The present state of physiology with regard to the existence and nature of the muscular sense is so unsatisfactory that it would be quite idle to occupy much space in the discussion of its pathology.

With regard to the existence of such sense there appears to be evidence similar to that which we possess in respect of other senses, viz. our consciousness of its existence. It is a matter of fact that we do know when, in what direction, and to what degree we contract our muscles. We guide our movements without looking at our limbs, we know where our extremities are placed, we determine movements when we like, and apportion the amount of effort to the task set before us; we guess at the weight of a body by the effort we make to raise it, and do not break an empty egg-shell if we hold it between our fingers in the dark. The patient with muscular anaesthesia has lost the power or faculty which renders these adjustments of movement possible. The fact of the existence of a muscular sense may be regarded as established, and also that of its distinctness from all other modes of sensation. It is tolerably certain that the peripheral expansion of the muscular-sense nerves exists in the muscular tissue itself, and not in either the skin or the structures around the joints; but beyond this point there is grave doubt even as to whether the fibres pass in the anterior or posterior roots of the spinal nerves. M. Trousseau‡ admits the existence of muscular sensibility, but denies

* De l'Ataxie locomotrice, Paris, 1864, p. 203.
† See article on Locomotor Ataxy, p. 336.
‡ Article "Ataxie locomotrice progressive," Nouveau Dictionnaire de Médecine et de Chirurgie pratiques, tome 3me, p. 777.
that of the sense of muscular activity; and the most important fact
upon which he bases his opinion is contained in the following words:
"Lorsque, fermant les yeux, nous exécutons sans efforts un mouvement
assez étendu, il nous est impossible, avec la plus sévère attention, de
sentir nos muscles se contracter; mais nous sentons le mouvement
imprimé aux leviers que la contraction des muscles met en jeu. Le fait
est si vrai, que si nous interrogeons une personne fort intelligente, mais
complètement étrangère aux notions anatomiques et physiologiques, et
si nous lui demandons quel est le siège du mouvement d'extension et de
flexion des doigts, elle le place exclusivement dans la main et jamais
dans l'avant-bras." This observation is quite correct, but M. Tronsean's
conclusion from it is, I think, erroneous. We do not see objects, nor
hear sounds in either our eyes or ears; but involuntarily project these
sensations, not into a distant part of our own body, but into space out-
side ourselves. The senses of taste, smell, and of tact, we refer to some-
thing or somewhere just beyond the extreme peripheral expansion of
the nerves which minister to those senses. We do not feel—or
mentally recognise as such—the condition of our own nerves, but
instinctively, and of necessity feel and believe in something outside our-
selves, or objective, that presses on the skin; something not ourselves
that we taste in our mouths; something not ourselves that we smell
in our noses. It is well known that a patient who has lost his leg
imagines that he feels pain in his amputated toes, and in this we have
another illustration of the principle that the mind does not refer sen-
sations to the spot which receives the impression which may occasion
it. Because, therefore, in the act of muscular movement our conscious-
ness refers the sense of such movement to the extremity moved, and
not to the moving organ, it is not proved that there is no sense of mus-
cular activity; on the contrary it is shown by this fact that the mus-
cular sense obeys a law similar to that which we recognise in regard
of other senses. For the existence of the sense we have the evidence
of consciousness, and for the absence of the sense, there is the
testimony of disease. It matters, comparatively speaking, little
for our present purpose to determine the exact nature or meta-
physical relations of the property in question; it is enough that in
health there is a faculty which has been called "muscular sense,"
and that in disease this function is destroyed; that such disease
may exist alone, and that the name by which it is denoted is
"Muscular Anaesthesia."

Prognosis.—The future of such cases cannot be predicted with
certainty. It may be guessed at by regard to conditions other than
those of the affection itself. If it be but one of many symptoms of
that manifold disease called hysteria, the prognosis is that of the
latter malady; if it be associated with grave changes in other portions
or functions of the nervous system, the nature of such ulterior symp-
toms must determine the prognosis. There is nothing special in the
character of the symptoms of muscular anaesthesia, *per se*, which can form a satisfactory guide.

TREATMENT.—Faradisation of the affected muscles has proved of service, as also has friction of the skin, and its electric irritation; but there are no medicines that have been shown to exert any special influence upon this variety of nervous disorder.
LOCOMOTOR ATAXY.

BY CHARLES BLAND RADCLIFFE, M.D. F.R.C.P.

Until very recently the disease which forms the subject of the present article was confounded with paraplegic diseases. The difficulty in locomotion, which is the most characteristic symptom, was supposed to be owing to simple paralytic weakness of the legs. It was not perceived that the legs, in the earlier stages of the disease at least, had lost little, if any, of their power to act separately—so little, indeed, that it might require all the force of a strong man to bend or straighten them against the will of the patient—and that what they had lost was that power of co-ordination by which the two limbs are enabled to act together, as they have to do in standing and moving about. The credit of having first drawn this distinction, and at the same time shown that this want of co-ordinating power is so associated with a definite group of other symptoms as to deserve to be regarded as a distinct disease, is due to Dr. Duchenne (de Boulogne). Before this time, no doubt, the characteristics of such a disease had been more or less clearly realized. They had been described, in fact, under the old name of tabes dorsalis, especially in the sketch of this disease given by Dr. Romberg. They had been detected by the late Dr. Todd, and not only so, but associated with that particular lesion with which they are now known to be connected, namely, with chronic disease of the posterior columns of the spinal cord. "Two kinds of paralysis of motion," wrote Dr. Todd, "may be noticed in the lower extremities,—the one consisting simply in the impairment, or loss of voluntary motion; the other distinguished by a diminution or total loss of the power of co-ordinating movements. In the latter form, while considerable voluntary power remains, the patient finds great difficulty in walking, and his gait is so tottering and uncertain, that his centre of gravity is easily displaced. The cases are generally of the most chronic kind, and many of them go on from day to day without any increase of the disease, or improvement of their condition. In two examples of this variety of paralysis I ventured to predict disease of the posterior columns, the diagnosis being founded upon the views of the functions of the columns which I advocate; and this was found to exist on a post-mortem inspection; and in looking through the accounts of recorded cases, in which the posterior columns were the seat of lesion, all seem to have com-
menced by evincing more or less disturbance of the locomotive powers." (Cyclopaedia of Anatomy and Phys., vol. iii. p. 721, S.)

Dr. Todd published these remarks in 1845; Dr. Duchenne's first memoir appeared in 1857. Dr. Todd must, therefore, have the credit of having anticipated Dr. Duchenne; but still the lion's share of honour must be assigned to the latter, for the plain fact is that Dr. Duchenne has developed in a series of formal memoirs what Dr. Todd has only indicated in these few sentences. In a word, it must be allowed that Dr. Duchenne deserves almost the entire credit of being the first to detect the exact features of the disease now known as progressive locomotor ataxy, and to call the attention of others to the subject.

The name of progressive locomotor ataxy (ataxic locomotrice progressive) from α (privative), and τάξις (order), is that which was chosen by Dr. Duchenne. It is not a very fortunate one, but it has been adopted, and must be retained, until a better one is found. It is certainly to be preferred to tabes dorsalis, for this name is commonly supposed to imply past incontinence on the part of the patient. How far it is right to perpetuate the cheerless affix progressive is, however, very questionable. At present, no doubt, the prognosis is full of gloom. From bad to worse is the common course of things, but, at the same time, there are cases—and their number is increasing every day—in which the symptoms have been long stationary, and others, in which there has been unequivocal amendment. But even if the element of hope were wanting, it is surely desirable not to bring this unhappy fact into undue prominence. It is surely not necessary to continue to use an epithet of which the effect must be to frighten the patient and discourage the practitioner, and this too without compensating advantages of any kind. As it seems to me, indeed, everything is gained by the name locomotor ataxy which is gained by the name progressive locomotor ataxy; and nothing is lost but what can well be spared; and therefore in what I have to say I shall drop the term 'progressive,' and speak simply of 'locomotor ataxy.'

1. As a text for what I have to say upon the symptoms of locomotor ataxy I take from my note-book a case which was not long ago (April, 1865) under my care in the National Hospital for the Paralysed and Epileptic:

Case.—A sailor, thirty-four years of age, by name J. C—, well proportioned, unusually well developed as to muscle everywhere, very lean, and much bronzed by long exposure to sun and sea.

(a) This man is capable of walking without a stick, but his gait is peculiar—staggering, precipitate, the legs starting about vaguely and spasmodically, and the heels coming down heavily at each step. With his eyes shut, or in the dark, he reels over at once and falls to the ground, if left to himself. Sitting or lying down, he can lift either leg steadily into any position, and fix it there so firmly that it is out of my power to bend or straighten it against his will. In order to do this, however, he must see what he has to do, for if his eyes are
shut, his limb at once becomes uncertain and unsteady in its movements, and comparatively powerless. His right leg is a little weaker than the left, but not in any well-marked degree. He finds it very difficult to come downstairs, or to turn round, or to quicken his pace much, and he is speedily fatigued by the acts of standing or walking. On being told to shut his eyes, and touch his nose with the forefinger of each hand in turn, he does so with tolerable accuracy, especially with the forefinger of the left hand. On being told to stretch out his arms, and keep them out, he does so, but only so long as he is allowed to see what he was doing; for, on holding a book up before his eyes, the arms, shoulders, neck, and head—the upper part of his body generally—at once became afflicted with convulsive agitation. When the book was taken away, these movements speedily came to an end, but not before they had issued in a fit of crying and sobbing which was not a little distressing to witness. This fit took the patient quite by surprise, and it could not be accounted for by the examination having been conducted roughly, or carried on for an undue length of time; indeed, the holding of the book before the eyes, which was the immediate cause of the fit, did not occupy more than a minute at the most.

The muscles of the lower limbs stand out firm and hard when made to contract by the will, and the contraction seems to be not at all wanting in force. Indeed, as has been already stated, it is out of my power to bend or extend the limb against the will of the patient. There is no tremulousness in the legs or elsewhere, and there are no marked reflex movements when the soles of the feet are tickled.

What is complained of chiefly are severe pangs of pain, stabbing, boring, shooting in flashes like lightning, flitting from one spot to another in a very erratic manner, recurring in paroxysms varying in length from a few minutes to twelve, twenty-four, or forty-eight hours, and generally remaining at the same spot during the same paroxysm. These pangs are most frequently felt in the two feet, especially along the outer side of the metatarsal bone of the little toe; and they also not unfrequently are met with at the back of the thigh, in the nates, and in the upper arm about the lower part of the belly of the biceps. They are scarcely ever absent, especially at night; at night, too, there is often a sensation of great coldness, with some degree of constriction at the seat of pain.

Tactile sensibility, measured by the compasses, is found to be much impaired in both feet, especially in the soles, in the calves of both legs, and to some degree also at the back of the thighs, in the nates, and in the palms of the hands. The ground is felt very obscurely, but, so far as it is felt, the sensations are accurate—that is to say, it does not seem as if there were elastic cushions, pebbles, or other imaginary bodies upon the floor, or as if the feet had nothing under them but free air, as is sometimes the case. Very rough pinching is scarcely at all felt in the benumbed parts, but elsewhere the sensibility to painful impressions is keen enough.
LOCOMOTOR ATAXY.

There is also evident impairment of the proper sensibility of the muscles, joints, and bones in the limbs, and especially in the legs. Thus, the patient never knows clearly where his feet are without looking at them, and now and then he has been so uncertain in this respect, that a foot has slipped out of bed without his being the wiser; and thus, again, his finger has not the power of discriminating between a sovereign and a shilling by the weight merely.

The sight of each eye is defective, and glasses afford no relief. The pupils are equal in size, and respond fairly to the light. The conjunctivæ are very much injected. There is no arcus senilis. There is no squinting or ptosis.

The hearing is so dull as to make it necessary to speak in a very loud tone in order to be heard, and one ear seems to be as deaf as the other. There are also constant singing and humming noises in the head—"I still hear the wind in the shrouds," he says.

The memory is bad, the spirits are despondent, and of late (this statement is volunteered by the patient) there has been a frequent disposition to commit suicide.

The pulse is feeble, and about 70 in the minute. The appetite is good. The bowels are somewhat constipated, and a long time is spent over a stool. The urine is voided slowly, and with difficulty, although there is no stricture, and now and then it escapes during sleep. Sexually, the state may be spoken of as approaching to spermatorrhœa.

(b) Five years ago J. C.—began to suffer from pains in the legs and back, and to be unsteady in his gait; about the same time, also, his sight and hearing began to fail; and from that time to this he has continued to get gradually worse and worse. Four years ago he had sun-stroke in the West Indies, of which the immediate symptoms were violent agitation and shaking, without loss of consciousness, and for which he was taken into a hospital and bled. But this accident was twelve months after his present malady had commenced, and therefore it is not possible to look upon it in the light of a cause. There never was either squinting or ptosis. He was at sea seventeen years in all, chiefly in hot climates, as the West Indies and the West Coast of Africa, and he remained on board three years after he had begun to suffer from unsteadiness of gait, and from the other symptoms which have been mentioned. Once during the time he was at sea he had chancres, without constitutional symptoms; and repeatedly he had diarrhoea, but, with these exceptions, his health on all occasions appears to have been pretty good. He says that he was always very careless, often sleeping, almost without clothes, on the bare deck, or on the ground, and that he was always "too much given to drink and women." For the last two years the sexual inclinations have been much damped, but before this time, from what he says, he appears to have been little better than a very satyr. Two years ago, when obliged to abandon his calling as a sailor, he was for a while treated in the hospital at Quebec for rheumatism. Afterwards he found his way to this country, and became an out-patient first at one hos-
pital and then at another. During this time he appears to have been frequently blistered along the spine, and on one occasion to have been salivated. For the rest, I have only to add that his father died early in life of consumption; that his mother died young of some unknown chronic disease; and that a brother, the only child besides himself, is now dying of the disease which proved fatal to his father.

This case has not yet ended in a post-mortem examination; and of eighteen other cases which have come under my notice, not one as yet is complete in this sense. All, therefore, that I can do is to say that in other cases of the kind the posterior columns of the spinal cord, and the posterior roots of the spinal nerves, are found to be diseased in the lumbo-dorsal region, and that the morbid appearances consist sometimes in a kind of grey degeneration, and sometimes in a gelatiniform and translucent condition, in a diminution of consistency, or in a state of induration called sclerosis. These changes are confined to the posterior columns of the cord, or if they extend further, it is not to the antero-lateral column, but only to the neighbouring portion of the posterior cornu of the central grey matter. In the majority of cases the disease is confined to the lumbo-dorsal portion of the cord, and it is only in quite exceptional instances that it extends upwards, so as to implicate the cervical portion. In the majority of cases, the diseased structure is more vascular than the healthy structure of which it has taken the place, the vessels being more or less deeply imbedded in oil globules of various sizes, and when examined further, it is found to be made up of atrophied and degenerated nerve-tissue, of the connective tissue in excess, and of amorphous granular matter. Now and then, also, traces of degeneration have been found at the roots or in the course of the optic nerves, or of one or other of the nerves of the muscles of the eye.

In order to see how far the case of which the notes have just been given agrees or disagrees with other cases of the kind, I single out as points to be noticed in turn, the following:—difficulty in standing or in moving about from inco-ordination of movement in the lower extremities; no true paralysis in the lower extremities; neuralgic pains, in the feet and legs more especially; more or less numbness in all forms of sensibility except that by which difference of temperature is recognised; impaired sight and hearing; no strabismus or ptosis; some incontinence of urine, and some want of control over the lower bowel, without marked paralysis of the bladder or sphincter ani; no obvious impairment of sexual power; no tingling or kindred phenomenon; no marked tremulous, convulsive, or spasmodic phenomena; no marked impairment of muscular nutrition and irritability; some impairment of mental and moral power; some injection of the conjunctivæ with contraction of the pupils; and, lastly, the probable limitation of the distinctive phenomenon of locomotor ataxy (the want of co-ordinating motor power) to the lower ex-
tremities.
LOCOMOTOR ATAXY.

Difficulty in standing or moving about from want of co-ordinating motor power to the lower extremities.—This difficulty is very evident, especially in the act of rising from a chair or in turning round suddenly when walking. If the patient cannot avail himself of some sufficient support at the time, the disorder in the movements of the legs produced by the act of rising from the sitting position, or of turning round suddenly when walking, is apt to throw him down. Walking is possible without a stick, but the gait is precipitate, staggering, the legs starting hither and thither vaguely, and the heels coming down at each step in a way which has gained for such patients at Gräfenburg the epithet of trampers. Moreover, it is less difficult to move on than to remain long in one position standing. In order either to stand or walk, however, the help of the sight is necessary. In less advanced forms of the disease, it may be difficult at first to detect inco-ordination in the movement of the legs, but this difficulty is not likely to last long. Often a first sign is reeling about upon getting out of bed in the dark. The patient may fall more than once under these circumstances, and think that he is only half awake or half sober. In that early stage of locomotor ataxy in which there is no evident inco-ordination of movement while the eyes are open, there is likely to be such disorder when the eyes are shut; and, in an earlier stage still, even when it may be possible to stand steadily with the eyes shut, provided the patient be allowed to plant his feet where he pleases, it is more than likely that he will lose his balance if he be made to stand with the inner edges of the feet in close apposition. In more advanced stages of the disease, walking, or even standing, becomes altogether impossible, and it is curious to notice the extreme disorder in the movements of the legs when the patient is propped up under the arms, and made to try to walk or stand; for under these circumstances the legs are seen to go every way but the right way—backwards, forwards, sideways, unless it happens, as it often does, that they get foul of each other, and become interlocked. In all cases, indeed, the inco-ordination of movement in the lower extremities, by which standing and moving about are interfered with in a greater or less degree, is a constant symptom in locomotor ataxy; and in a case of average severity, like the one under consideration, the gait, arising from this want of co-ordination, is quite characteristic—namely, precipitate, staggering, the legs starting hither and thither, and the heels coming down with a stamp at each step.

No true paralysis in the lower extremities.—When the patient is sitting or lying he can, provided he sees what he is doing, move either leg singly into any position with tolerable precision, and keep it there steadily; and the muscular force at his command is such, that it is out of my power to straighten the limb if bent, or to bend it if straightened. There is plainly no paralysis. Nor is it otherwise in other cases of locomotor ataxy, not even in those extreme cases in which the inco-ordination of movement in the legs has proceeded to the
extent of making even standing an impossibility. And, certainly, it is no objection to the conclusion that my patient was speedily fatigued by the acts of standing or walking, for in reality this fatigue may easily be accounted for by referring it to the effort necessary to keep the ataxic movements of the legs in check.

*Paroxysms of neuralgic pain, in the feet and legs principally.*—My patient's chief complaint was of neuralgic pains—pain boring, stabbing, or shooting in their character, pains like those caused by a sharp electric shock—in various parts of the lower extremities, in the feet especially, and sometimes in the arms and abdomen, occurring in paroxysms varying in duration from a few minutes to many hours, flitting from one spot to another, but generally remaining at the same spot in the same paroxysm. And this was the chief complaint from the very beginning of the malady. Nor is this case at all exceptional in this respect: on the contrary, pain of the same character is met with in the great majority of cases of locomotor ataxy. Moreover, Dr. Trouseau speaks of this symptom as the most constant precursory phenomenon of the disease. In some cases, no doubt, pain is either absent altogether, or present only as an occasional symptom of very secondary importance. I have myself met with four cases of well marked locomotor ataxy in which there was no pain, or none to speak of. The pain may begin in a way in which it may be mistaken for rheumatism, and be slow in acquiring its special character, but it has, as a rule, these special neuralgic characters from the first throughout.

*Numbness in all the forms of sensibility excepting that by which differences of temperature are recognised.*—In the case under consideration the sense of touch is almost annihilated in the soles of the feet and in the lower calves of both legs, and it is impaired greatly in the back of the thighs, in the nates to a less degree, and in the palms of both hands. In the parts also which are thus benumbed tickling is felt very obscurely, or not at all, and very trifling pain or none at all is caused by pinching or pricking. In the legs also the "muscular sense," as well as the special sensibility of the joints and bones, are considerably impaired, as is evident in the fact that the patient does not know where his feet are unless he can see them. Indeed, the only form of sensibility which seems to be unimpaired, is that by which are recognised differences of temperature. In other cases of locomotor ataxy, also, a similar state of things as to sensation would seem to be the almost constant rule, the numbness beginning, first in tactility, then in the sensibility to pain and tickling, afterwards passing to the "muscular sense," and always, curiously, skipping over, or leaving off before reaching, the endowment by which differences of temperature are perceived. In some instances the sensibility of the mucous membrane of the anus and urethra is greatly deadened. The numbness is most marked in the lower extremities, especially in the feet, and very often it is confined to these parts, but now and then it may extend further. I know of one case in which
the tip of the nose and the middle of the upper and lower lip are thus affected.

It would seem to be the rule for numbness to make its appearance at the same time as inco-ordination of movement, and for the two symptoms to make progress pari passu; but there are cases of locomotor ataxy in which, to say the least, numbness in any form is a very inconspicuous phenomenon. Moreover, it is certain that cases of well-marked locomotor ataxy are met with in which the "muscular sense" is not affected. Out of nineteen cases, I have met with two such. I believe, also, that in cases of locomotor ataxy in which the "muscular sense" is affected considerably, it will be often found that this form of numbness makes its appearance after the inco-ordination of movement, and not before it. In a word, I believe that the history of locomotor ataxy furnishes little countenance to a theory which has been advanced—that the inco-ordination of movement in this disorder is nothing more than the consequence of loss of muscular sense.

In some exceptional cases of locomotor ataxy there may be numbness in some parts, and an opposite state of things in others. Thus, I have myself met with a case in which there is anaesthesia almost complete in the lower extremities generally, and the most distressing hyperaesthesia as to tickling in the thumb. But, as I have said, cases of this kind are quite exceptional.

Impairment of sight and hearing.—Impairment of sight appears to be a common symptom in locomotor ataxy; impairment of hearing an occasional symptom.*

No strabismus or ptosis.—Dr. Duchenne and Dr. Trousseau both speak of strabismus or ptosis—internal strabismus, from paralysis of the sixth cranial nerve, external strabismus, diplopia, and ptosis, from paralysis of the third cranial nerve,—as frequently met with in the early stage of locomotor ataxy, as frequently passing off after a time, and not unfrequently as returning, to remain permanently, at a later period. Dr. Duchenne has also twice met with paralysis of the fifth cranial nerve concurrently with paralysis of the third. Speaking of these symptoms, Dr. Trousseau says, "Some may be absent, but it rarely occurs that they are all absent in the same case. I have nearly always found them, and Dr. Duchenne is right in attaching great importance to them for diagnosing the disease at the onset. Remember, besides, that they may have been transitory, and been forgotten by the patient, so that the physician must needs make careful inquiries in order to discover their existence in the patient's previous history." Ptosis or strabismus were not present in the case which I have given, and they never had been; and the same may be said of seven out of eighteen other cases of locomotor ataxy which have come under my notice. In the remaining eleven

* My friend and colleague Dr. Hugling Jackson has shown that in the cases where sight is impaired or lost there is a gradual whitening of the optic disc without any marked change in the size of the retinal arteries and veins—a chronic form of atrophy which is more common in men than women, and which is not at all peculiar to locomotor ataxy.
cases, strabismus or ptosis, one or both were either present at the time of observation, or had been present for a time at an earlier period, generally at the onset of the disease. I find, also, as Dr. Trousseau did, that these paralytic affections of the muscles of the eye, or the impairment of sight or hearing, may be present at an early stage of the disease, may disappear for a while, and then reappear at a later stage.

No very obvious paralytic condition of the bladder or lower bowel.—Incontinence of urine at night, and now and then at other times, as after unusual fatigue, is a common and often a very early symptom in locomotor ataxy, and a less common, and usually a comparatively late symptom, is some trifling want of control over the lower bowel. Dr. Trousseau, speaking of the phenomena of the fully-developed disease, says, "just as in confirmed cases of paraplegia, there is paresis of the bladder and rectum, or even paralysis of the sphincters." As it seems to me, however, there is a marked difference between cases of confirmed locomotor ataxy and common paraplegia in these respects, the difference being that in locomotor ataxy there is not that obvious state of paralysis of the bladder, or sphincter ani, which is so generally present in paraplegia. Indeed, I have never met with a case of locomotor ataxy in which the way in which the bladder could be emptied in a steady stream, did not prove that this viscus retained a fair amount of power; and in one or two cases of this disease, in which the feces have passed involuntarily at times, I have found a state of things which enabled me to account for this accident without assuming the existence of paralysis of the sphincter ani, namely, a want of sufficient sensitiveness about the anus. Moreover, I do not find in the cases which have come under my notice one in which the urine was retained, as it so often is in paraplegia, and where the consequences of such retention, cystitis, alkaline urine, and the rest, were present. Indeed, in all my cases the urine has been acid, and otherwise healthy—a state of things which is scarcely compatible with the presence of paralysis of the bladder.

No obvious impairment of sexual power.—From a sexual point of view, it is easy to see that, as a rule, there is a marked difference between locomotor ataxy and common paraplegia, the difference being that in the former disorder there is not that impairment of desire and power which is so constantly met with in the latter. Not unfrequently, indeed, it is plain that there is no impairment of sexual power in ataxy; and now and then there is a curious exaggeration of virility, evidenced, it may be, in the aptitude to repeated acts of connexon within a short period. Thus, Dr. Trousseau instances two cases in which these acts could be repeated as often as eight, nine, or ten times in a single night, and I have met with one case which is a fit fellow to these. In all these cases spermatorrhœa was a symptom. I also know of two cases of advanced locomotor ataxy in which fertilization has been successfully effected, and other cases of the kind are on record.
LOCOMOTOR ATAXY.

No tingling or kindred phenomena.—Tingling, or sensations analogous to tingling, are not among the symptoms noted in the cases of locomotor ataxy, which have come under my own notice, and, so far as I know, they have not occurred in other cases of the kind. At any rate, I think it cannot be doubted that such symptoms are infinitely more common in common chronic paraplegia than in locomotor ataxy.

No obvious tremulous, convulsive, or spasmodic phenomena.—Dr. Trousseau says:—"At an advanced period of locomotor ataxy, spasmodic contractions are frequently observed, not only when the patient wills a regular movement, but even in the state of rest. In the latter case, they consist in very powerful jerks of the limbs, and are an important symptom of this singular neurosis." But my experience of the disease does not bear out this statement. Moreover, the cases given by my friend and colleague, Dr. Bazire, in the valuable appendix to his translation of Dr. Trousseau's lecture on locomotor ataxy, is not confirmatory of the passage in the lecture which I have just quoted. Indeed, if I except certain attacks of convulsive agitation, in which one or two patients have now and then awakened out of sleep, and the feeling of constriction in the abdomen and lower extremities, which is occasionally met with, and which may possibly have some remote connexion with spasm, I know of nothing in the history of locomotor ataxy which requires a place in the category of tremulous, convulsive, or spasmodic phenomena.

No marked impairment of muscular nutrition and irritability.—This is another feature of locomotor ataxy, and, therefore, another point of difference between this affection and common paraplegia. The electro-sensibility is impaired in the muscles in which the "muscular sense" is impaired, not the electro-contractility.

Some impairment of mental and moral power.—Bad memory, despondency, suicidal tendency, are mentioned among the symptoms in the case which serves as my text, but troubles of this kind do not figure in the history of other cases of locomotor ataxy. In fact, it would seem to be the almost constant rule for the mental faculties to be unscathed in this disease.

Some injection of conjunctivae with contraction of pupils.—In the case under consideration, the pupils were contracted and comparatively disobedient to light, and the whites of the eyes were considerably bloodshot; and this appears to be a not unusual state of things in cases of the kind. Dr. Trousseau says that he has often noticed in atactic patients, in the intervals between the paroxysms of pain, injection of the conjunctivae, sometimes as marked as in the most violent conjunctivitis, sometimes amounting to a sort of chemosis, and, in association with this, a state of extreme contraction of the pupils; and he also tells us that he has seen this injection of the conjunctivae and contraction of the pupils disappear during a paroxysm of pain. In J. C.—, I failed to perceive this change during pain. Dr. Bazire also failed to perceive it in others who have come under his notice. I have observed dit in two cases, of which that of my friend M. Ernst,
the prince of violinists, was one. In these two cases, what I noticed was this—that the eyes ceased to be bloodshot, and the pupils opened when the pain reached a certain degree of severity and continued for a certain time, and not otherwise. This I observed on several occasions in M. Ernst while he was staying with me on a visit, and I expect that the discrepancy which at present exists between the statements of Dr. Trousseau and his translator upon this point, will disappear as soon as the influence of the degree and duration of the pain is taken into account.

*The probable limitation of the distinctive phenomenon of locomotor ataxy (the want of co-ordinating motor power) to the lower extremities.*

—In many cases of locomotor ataxy the upper extremities are not affected at all; in others, their sensibility is blunted in one form or other, and their movements are wanting in precision, especially if the sight be defective, or the eyelids closed. In the cases in which the movements of the upper extremities are wanting in precision, there is always, so far as I know, more or less impairment of sensibility, of the “muscular sense” perhaps most frequently; and my belief is, that the want of precision in movement is rather to be ascribed to the want of the proper guidance of sensation than in the loss of any co-ordinating motor power. One ground for this belief is the fact that the disease of the posterior columns of the cord which is met with in locomotor ataxy, and upon which, there is every reason to believe, the want of proper co-ordination in movement is dependent, is confined to the lumbo-dorsal region of the cord in the great mass of cases. Another ground for this belief is in the character of the movements themselves, for the fumbling, groping movements, which I have seen now and then in the upper extremities of persons suffering from locomotor ataxy, never seem to me to be of the true ataxic kind which are met with in the lower extremities. Moreover, it is to be remembered that the movements of the arms in a biped like man are not so interdependent as the movements of the legs, and that, on this account, movements of inco-ordination are less likely to occur in the arms than in the legs. The only case with what seemed to be ataxic movements in the arms as well as in the legs which has come under my own notice is one which, on reflection, seems rather to confirm the conclusion at which I have arrived than to contradict it. The patient was totally blind and bedridden, and all but totally deprived of all kinds of sensibility in the arms, and of the “muscular sense” in the legs. The case, indeed, is one of much interest, and I quote it not only as a fitting comment upon the question at issue, but also as an illustration of the way in which the symptoms of locomotor ataxy may interblend with, or be toned down into, those of kindred affections.

*Case.*—C. G——, a married woman aged 36, admitted under my care into the National Hospital for the Paralysed and Epileptic on the 27th November, 1866.

(a) This poor woman is bedridden and perfectly blind. She can, if not
lying too flat on her back, quickly and easily change from the lying to the sitting posture, and back again from the sitting to the lying, and she can move her arms and legs about, but these movements are curiously vague, irregular, and, as it were, constrained, in the legs especially. She cannot feed herself, or help herself in any way. In the *upper extremities*, almost as high as the shoulders, and on the left side particularly, the sensibility to touch, tickling, pain, temperature, and the electro-sensibility, are blunted in a very high degree. With neither hand can she tell the difference between my bare hand and my hand with a woollen glove upon it; between pinching or pricking very sharply, and tickling only; between a cold delf plate and a warm poker. The "muscular sense" is also much impaired in both arms, in the left especially. The right hand can be moved to the mouth, or made to clasp the other hand, but very stiffly and awkwardly, and only after making many zigzag deviations to one side or the other; the left hand moves hither and thither, often in the opposite direction to that in which it is intended to move it, and in which it is supposed to be moved, and it can perform neither of the movements which have just been instanced as being performed with difficulty by the right hand. If the left arm be in contact with the body, the patient knows where it is, not otherwise. In both upper extremities the muscles are not at all wasted, the electro-contractility is perfect, and the amount of muscular power at the command of the will by no means inconsiderable. The patient herself describes the muscles as feeling somewhat rigid, and so they are in fact; and it is owing to this rigidity, evidently, that the movements of the upper extremities have that constrained character which has been mentioned. In the *lower extremities*, quite as high as the hips, the state as regards touch, pain, tickling, temperature, and electro-sensibility is the very opposite to that which is met with in the upper extremities, there being no manifest impairment in any one of these endowments. As in the arms so in the legs, the "muscular sense" is all but annihilated. So blunted is this sense, indeed, that the patient is not certain whether the legs are crossed or not, whether they are in bed or out; and it has happened more than once that she has been thrown over in bed or out of bed, in consequence of sitting up suddenly while her legs have been crossed or twisted in some awkward manner. The muscles of the legs are not wasted, neither is their electro-motility sensibly impaired, but their voluntary movements are considerably restrained and limited by a state of slight muscular rigidity which seems to be increased by movement.

No complaint is made of pain, or of any other uncomfortable feeling anywhere.

The urine is natural, and the bladder acts properly. The appetite and digestion are in excellent order. The bowels are constipated, but the sphincter ani does its work quite well. The mind is clear, the memory good. The spirits are surprisingly buoyant, and the senses of smell and hearing very acute. There is no perceptible lesion of
sensibility or motility in the head, neck, and trunk, with the single exception of the total loss of sight already mentioned.

(b) In August, 1864, this poor woman was frightened into what she calls "hysterics," by a fire in her room, caused by the oversetting of a camphine lamp. In this attack she tossed her limbs about wildly, and gasped for breath a good deal, but she did not lose her consciousness. Very soon afterwards the thumb of her right hand went "asleep," and the sight became so dim as to make it difficult for her to help her husband, as she had hitherto done, in his work as a tailor. During the next two months the sleepiness or numbness which began in the right thumb extended to nearly the whole of both upper extremities, the starting-point on the left side being also in the thumb. At the beginning of 1865, she tumbled about so as to make it almost impossible to stand or walk, and in the spring of this year she could neither stand, nor walk, nor see; and in this state, bedridden, utterly helpless and blind, she seems to have remained, with little or no change, ever since. Three years before the fright which has been mentioned, and which is looked upon by the patient as the starting-point of her disease, she had what she calls sharp rheumatic pains flying about from one place to another in her legs, and these pains have continued, with intervals of longer or shorter duration, ever since. She said that these pains were worse when her husband was out of work, and that she had no pain to speak of when she could have her glass of beer to supper; and also that when the pains were most severe, they were accompanied by some startings, and a feeling of increased stiffness in the legs and arms, as well as by greater irregularity in the movements of the limbs, and greater uncertainty as to the degree and direction of these movements.

(c) During the two months this patient remained in the hospital she was free from pain, but in other respects her state underwent no change for the better.

With respect to this case, I will only say that it cannot be regarded as a pure case of locomotor ataxy. The muscular rigidity in itself is a sufficient proof of this. Moreover, in it anaesthesia muscularis is a much more prominent phenomenon than in the generality of cases of locomotor ataxy, and, in short, to come back to the point from which I started, there is no difficulty in believing that the irregular movements of the arms exhibited in it (and possibly those of the legs also) may be due, not to impairment in co-ordinating motor power, but simply to the muscular anaesthesia and the blindness.

Looking back, then, at the first case which has been cited, and at the comments to which it has given rise, it is not difficult to see that locomotor ataxy is characterised by these symptoms:—

A peculiar gait arising from want of co-ordinating motor power in the lower extremities—a gait precipitate and staggering, the legs starting hither and thither in a very disorderly manner, and the heels coming down with a stamp at each step.
LOCOMOTOR ATAXY.

No true paralysis in the lower extremities or elsewhere.
Characteristic neuralgic pains, erratic, paroxysmal, in the feet and legs chiefly—pains of a boring, throbbing, shooting character, like those caused by a sharp electric shock.

More or less numbness, in the feet and legs chiefly, in all forms of sensibility, excepting that by which differences of temperature are recognised.

Frequent impairment of sight or hearing, one or both.
Frequent transitory or permanent strabismus or ptosis, one or both.
No very obvious paralysis of the bladder or lower bowel.
No necessary impairment of sexual power.
No tingling or kindred phenomenon.
No marked tremulous, convulsive, or spasmodic phenomena.
No marked impairment of muscular nutrition and irritability.
No impairment of the mental faculties.
Occasional injection of the conjunctivae with contraction of the pupils.

The probable limitation of the distinctive phenomenon of locomotor ataxy (the want of co-ordinating motor power) to the lower extremities.

For the rest, I will only say that a chronic disease with these characteristics, and without fever or other signs of disordered health, may safely be pronounced to be locomotor ataxy.

Dr. Duchenne, whose description of the disease is the best as well as the first, marks out three stages in locomotor ataxy. In the first stage the patient suffers from paralysis, often only temporary, of one or other of the motor nerves of the eye, from some degree of anærosis, usually accompanied with unequal pupils, and from the peculiar neuralgic pains. In the second stage the characteristic unsteadiness in standing and moving about begins to show itself together with anaesthæsia, the interval between the first stage and the second varying from a few months to several years. In the third stage the malady becomes more profound and general, but the precise point at which the second stage ends and the third stage begins is not very clearly defined.

Dr. Duchenne does not regard the affection of the bladder, the rectum, and the genital apparatus as essential symptoms of the disease in any of these three stages; he regards them as épiphenomènes only. Dr. Trousseau does not divide the disease into distinct stages, but he speaks of a premonitory stage in which paroxysms of pain, spermatorrhœa or impotence, paralysis of one or other of the motor nerves of the eye, and disorder of vision are the symptoms to be met with. As Dr. Bazire says, however, "it is hardly possible to regard these merely in the light of premonitory symptoms, because they form part and parcel of the fully developed disease," and, in fact, the various symptoms are so mixed up together, and make their début at such varying periods, that it is not easy to separate symptoms and arrange them in this stage or that.

2. Females are, without doubt, far less liable to locomotor ataxy
than males: and this is not to be wondered at, for, as Dr. Bazire has pointed out, this relative protection of the female sex seems to obtain in all forms of disease of the spinal cord, seeing that out of 177 cases tabulated by Dr. Brown-Séquard, 128 occurred in males and only 49 in women.

Locomotor ataxy is also a disorder of adult life. In 19 cases which have come under my own notice, the age varies from 23 to 60; and but few cases are on record in which the patient was under 20. Indeed the only cases under twenty would seem to be three reported by Dr. Freidreich of Heidelberg, of which the ages respectively are 18, 16, and 15 years.

3. In some cases sexual excess would seem to figure as a cause, but not in others—not perhaps by any means in the majority. And this is one reason why it is not well to continue to use the name of tabes dorsalis as the equivalent of locomotor ataxy, for rightly or wrongly it has come to this, that the name tabes dorsalis is supposed to imply past abuse of the sexual organs. Nor is it possible to speak of syphilis, or rheumatism, or gout, or struma as a cause, for in a great many cases, to say the least, there is no evidence of one or other of these morbid conditions. In fact, it is not possible to refer locomotor ataxy to any special cause. What predisposes to other diseases of the nervous system predisposes to this, family predisposition especially, and this is all that can be said. With regard to family predisposition some curious instances might be given. I know of one case in which one brother is epileptic, another brother hypochondriac, and two sisters are suffering from different forms of paralysis; and Dr. Marius Carré instances a family in which eighteen members have become ataxic in turn, namely, the grandmother, the mother, eight relations of the latter, seven children, and one cousin.

4. The prognosis of the disease is unhappily full of gloom. Usually, without doubt, the course is slowly but steadily in a downward direction—so slowly, often, that it is only after the lapse of many months, or even years, that the patient distinctly realizes the fact of having become decidedly worse; but on the other hand, several cases are on record in which the disease has advanced to the extent of destroying the power of standing and walking in four or five months. Long pauses in the progress of the disease are not uncommon; thus, for example, I know of one case in which the condition has remained stationary for fourteen years. Moreover, it is not impossible to find a few cases in which the symptoms have changed for the better considerably, and are still changing. Cases of this kind, it is true, are not very common, but they are to be met with. I myself can testify to the existence of two of them.

5. Locomotor ataxy, it is said, may be confounded with several diseases, especially with common chronic paraplegia, with simple loss of "muscular sense" with cerebellar disease, and with chorea, but this can scarcely be if only moderate care be taken.

In common chronic paraplegia there is unequivocal paralysis in the
lower extremities, and the nutrition and irritability of the paralysed muscles are, as a rule, unmistakeably impaired. In these fundamental particulars, indeed, the difference between this affection and locomotor ataxy is as complete as it can be. In common chronic paraplegia the bladder and sphincter ani are implicated in the paralysis which affects the legs, and the sexual power is almost sure to be greatly weakened or entirely extinguished. In common chronic paraplegia the characteristic neuralgic pains of locomotor ataxy are wanting, and numbness is nothing like so prominent a symptom as in the atactic disorder. In common chronic paraplegia, where walking is possible, the gait, instead of exhibiting the want of co-ordination which is met with in locomotor ataxy, is hampered and slow, each leg being brought forward with evident difficulty even with the help of an upward hitch of the body on the same side, and the part of the foot first coming in contact with the ground being, as a rule, not the heel as in ataxy, but the toes. In common chronic paraplegia impairment of sight or hearing, strabismus or ptosis, injection of the conjunctive, or contraction of the pupils, frequent, if not constant, symptoms in ataxy, form no part of the history. In fact, in these respects, and in others of minor importance, which might be mentioned, the histories of common chronic paraplegia and of locomotor ataxy are so different that it is not easy to see how, with only an ordinary amount of care, the two disorders can be confounded.*

In some diseases of the cerebellum there appears to be, often at least, the same disorder of muscular movement which is met with in locomotor ataxy, but this resemblance is more apparent than real. In the next bed to that then occupied by the patient whose case has served as an instance of locomotor ataxy, was a boy, also under my care, whose cerebellum never seemed to have been properly developed, and whose gait was precisely that which I have seen in two cases of tumour of the cerebellum, and which seems to be associated with serious cerebellar disease in all cases. This boy reeled and rolled about in walking, but there was nothing peculiar in the way in which he moved his legs and planted his feet: on the contrary, these movements were those which would be instinctively made to prevent falling. He was not giddy, but he seemed to be giddy, and the volitional and automatic movements of his legs were what they ought to be under the circumstances, no more. His mode of progression was widely different from that of the atactic patient, as was at once apparent when the two were set to walk side by side, how different I need not again stay to say. In certain diseases of the cerebellum, also, some symptoms are likely to be present which will

* The atactic movements which depend upon anesthesia muscularis are only present when the patient does not see what he is doing: the atactic movements which characterize simple locomotor ataxy continue whether the patient see what he is doing or not. Nor is this simple rule in diagnosis invalidated by the fact that in the majority of cases of locomotor ataxy the sight has a marked influence in keeping the unruly muscles in check, for the cases are almost exceptional in which loss of muscular sense does not form an important element in the disorder.
assist in the formation of a correct diagnosis, especially violent pain, often augmented by movement, in one or other part of the head, and frequent and obstinate vomiting, and at the same time other symptoms are likely to be absent which are present in locomotor ataxy, namely, neuralgic pains and anesthesia in the feet and legs, and elsewhere.

In chorea there is great want of co-ordinating motor power, but the history is quite different from that of locomotor ataxy. Chorea is an affection of childhood and early youth: locomotor ataxy of adult life. The choreic muscular disturbances affect especially the head and arms; the ataxic, are confined to the legs. Moreover, there are not in locomotor ataxy those involuntary movements which in chorea keep the affected muscles in a state of almost perpetual unrest. And as to the other symptoms it is, in fact, a question of differences, not of similarities.

It must not be forgotten, however, that the different diseases of the nervous system, like all other diseases, are not fenced in by any boundaries except those which have been fixed almost arbitrarily for the convenience of description, and that cases of a mixed character are continually being met with; which in reality lie across these boundaries in every direction.

6. The treatment of locomotor ataxy is not a subject upon which much can be said at present. No specific treatment can be recommended on good grounds, not even that by nitrate of silver, about which so much has been said of late in Germany and France; and the only treatment which finds favour in my eyes is one of a general character in which figure some preparation of phosphorus with or without cod liver oil, or arsenic, or bichloride of mercury. I should endeavour to act upon general principles, meeting as well as I could any special indication, as syphilis, or gout, or rheumatism, or struma. I should trust to a liberal allowance of stimulants rather than to sedatives for the relief of pain; and for the relief of pain also I should have much confidence in regular shampooing, in faradization, and the use of positive statical electricity. I am also disposed to think that good may be done by taking care that the patient never went about without crutches. What is chiefly at fault is the motor power by which the two legs act in concert in standing and moving about: and what is wanted primarily is to do away, as far as possible, with the necessity for calling into exercise this power until it can have had time to recover by rest. This is an intelligible indication, and the use of crutches is an intelligible means of carrying it out. Perhaps it is too much to expect that great good can be done in any way in advanced stages of the disease: but in early stages I cannot but think that the disease, to say the least, might be arrested if the patient would consent for a longer or shorter time to use crutches, and in this way to descend, as it were, from the position of a biped to that of a quadruped. For surely it must go far to neutralize the good to be derived from treatment if the patient is continually trying to
do, by walking about without help, or with only the imperfect support of a stick, what the diseased condition of his spinal cord incapacitates him from doing. Nor are these remarks alone applicable to the treatment of locomotor ataxy: on the contrary, they apply equally to the treatment of all forms of spinal disease in which the acts of standing and moving about are at all compromised.
B. Partial Diseases of the Nervous System.

      Congestion of the Brain.  Abscess.
      Cerebritis.  Cerebral Hæmorrhage.
      Softening.  Adventitious Products.
SIMPLE MENINGITIS.

BY J. SPENCE RAMSKILL, M.D.

Definition.—By Meningitis is generally meant inflammation of the pia-mater and arachnoid. Inflammation of the dura-mater is described separately. Attempts have been made to separate inflammation of the arachnoid from that of the pia-mater, and some, as Lallemand, Parent-Duchâtelet, and Martinet, have even gone so far as to apply the term Arachnitis to inflammation of the arachnoid, on the ground that the serous membrane was the one chiefly affected. But an analysis of the cases given by the very advocates of that opinion show most conclusively that the pia-mater is in all cases affected, and always bears more marked evidences of inflammation than the arachnoid. There is no symptom which, during life, could help to distinguish between inflammation affecting the pia-mater and inflammation involving the arachnoid alone; and as the treatment in either case would be the same, there would be no practical advantage gained by such a distinction. Cerebral Fever is a name given by Trousseau to various acute affections of the head in children, amongst which he includes Meningitis. Meningitis may be primary or secondary; uncomplicated or complicated; acute or chronic.

Acute Meningitis. Symptoms.—In some rare cases, certain pro-dromata precede the invasion of the disease, in the shape of slight but increasing pains of the head, irritability of temper, sleeplessness, and general malaise. But, as a rule, the invasion of the disease is decided, and from the outset its gravity is not to be mistaken. Its course may be divided into three stages:—1st, a period of excitement; 2d, a period of transition; 3d, the stage of collapse. These three stages are not always present, nor are they always distinctly marked. When the disease is very violent, the first stage may rapidly pass into the third, or comatose period. In old and feeble people the first stage may either be absent altogether, or be so little marked as to escape observation. Again, the third stage may be absent, from life being abruptly cut short by violent general convulsions in the second period; and lastly, the first and third stages may coalesce during the transition from one to the other, and may present mixed phenomena of delirium alternating with coma.

Stage First. Period of excitement.—A well-marked rigor, with pallor of the surface and cutis anscriina, opens the scene, and is very quickly
followed by intense febrile reaction. In very young children a paroxysm of general convulsions may be the first symptom; in adults, however, convulsions are the exception. The fever is very high; the skin is hot and dry; the pulse frequent, sharp, and hard; the face flushed, particularly about the malar bones: sometimes it is alternately flushed and pale. The eyes are glistening, the conjunctivae injected; the pupils in this stage are usually contracted; there is photophobia, and, in order to keep the light out, the patient keeps his eyes firmly closed, and resists all attempts at opening them on the part of the practitioner. There is sometimes strabismus on one or both sides, particularly in children. Acoustic hyperæsthesia distresses the patient; the least sound, the lightest footstep about the room, gives him pain. Cephalalgia of the most acute character sets in from the first. It is referred to the forehead, vertex, temples, or occiput, or to the head generally: pressure on the scalp increases, and movement intensifies it; hence, in order to prevent his head from moving, the patient holds it between his hands. Sensorial impressions of light and sound also exaggerate it. The pain is continuous, but presents also frequent exacerbations, during which, the patient, especially if a child, utters a peculiar loud piercing cry. The headache may precede the other symptoms for a day or two, or for a few hours only, or it may appear simultaneously with them. It is the most striking symptom of the disease; it is present in nearly every case, but not in all; and Andral has related in his "Clinique Médicale," cases in which it was absent from first to last; and, in one of these, sero-purulent effusion was found in the lateral ventricles after death. The intensity of the pain does not bear any relation to the stage of the inflammation and the nature of its products. Thus, it has been found as severe in cases where a post-mortem examination disclosed mere injection and increased vascularity of the meninges, as in cases of serous or purulent infiltration of the membranes, or when false membranes had time to develop. The extent over which it is felt is not proportionate to that of the inflammation, for it may be felt all over the head, and yet the Meningitis be partial only; on the other hand, it may be exactly limited to one particular spot, and yet the inflammation be general. When partial, it does not always correspond to the exact seat of the inflammation, although when an individual complains of a fixed pain in a spot never varying, the probability is, that the meninges are inflamed at that point. The cephalalgia of Meningitis differs from that of continued fevers in its intensity, and in the fact that the patient does not wait, as in the latter, till asked whether he has any pain in his head, before speaking of it himself; and craving for relief. The character of the pain varies; it is described by some as a heavy weight pressing on their brain; by others, as consisting in violent shooting pains, either continuous or recurring at intervals. Sometimes, again, it is compared to the sensation of an iron band encircling the forehead, or of the head being squeezed in a vice. Vomiting is another well-marked symptom of acute simple Menin-
gitis. It is purely sympathetic, and is unattended with epigastric pain or tenderness on pressure, or with nausea. It recurs very frequently for the first day or two of the disease, and may then cease; but, in some cases it persists unto the end, either continuously, or with more or less prolonged intermission. The matters vomited are abundant in quantity, and are mixed with bile. The tongue is natural, generally moist, and occasionally covered with a white creamy fur. Constipation is the rule, and the discharges, when there are any, are dark, and offensive.

The intellect is always affected from an early period. The temper is extremely irritable; there is marked somnolence or constant wakefulness, or the one may alternate with the other for several days. Delirium sets in early; it is generally of a wild, fierce character, the patient shouting and vociferating, and tossing himself about. In some cases, on the contrary, the first sign of intellectual disorder is obstinate mutism, the patient burying his head under the bed-clothes and refusing to answer questions. Sometimes the delirium reaches at once its maximum on its first occurrence, but otherwise it is slight at first and gradually becomes more and more marked. Sometimes, again, it is only nocturnal at the outset, and does not become diurnal until after a few days; and again, a patient who has been wildly delirious for a few days may recover his reason before death, although all his other symptoms grow worse.

From the beginning the patient staggers when walking, and his gait resembles that of a man under the influence of drink. When he has taken to his bed, he is extremely restless, and keeps constantly shifting his position. The muscles of his face and limbs, even in this stage, may begin to twitch involuntarily. When convulsions have opened the scene, as they frequently do in young children, they recur in frequent paroxysms one upon the other with scarcely any intermissions. The general sensibility is usually heightened in this stage, although it has sometimes been known to be normal. To sum up, the characteristics of the first stage are: high fever, cephalalgia, an occasional sharp piercing cry, vomiting and constipation, general hyperesthesia, sensorial and cutaneous, and fierce delirium. This stage may last only a day or two, but generally extends over a week, and sometimes over two weeks. It then merges into the second or transition period.

Stage Second.—The delirium becomes quieter; there is carphology, picking at imaginary flies in the air, or on the bed-clothes; and the patient's eyes become dim and lustreless: his pupils dilate, or they oscillate at first before they dilate, and become insensible to the influence of light. Vision is impaired; hearing gets dull. The patient complains less often of his headache, because he is less sensible; occasionally, however, he utters still a loud cry, he grinds his teeth, moving his jaw as if he were chewing, and rolls his head from side to side, boring his pillow with his occiput. Somnolence sets in, to be soon followed by a comatose condition. The pulse is less frequent,
SIMPLE MENINGITIS.

and occasionally intermits. The respiration is very irregular; at one time it is very rapid, and the next moment it is slow and suspirious, made up of a long, deep inspiration, followed by a slow and long sustained expiration. The urine is retained, or there may be sti̇llicidium after retention. The constipation persists; and the abdomen is apt to become retracted, sunken, and almost boat-shaped. The general hyperæsthesia is now replaced by hypæsthesia, which soon makes way for complete anaesthesia. The muscular twitchings increase; there is subsultus tendinum, and actual convulsions often set in. These may be general or partial, generally the latter, and they then attack different parts successively. The muscles most commonly affected are those of the eyeballs, producing strabismus, or rolling upward of the globes; the muscles of the face and lips, and lastly, of the extremities. The tongue itself may be the seat of convulsions. There may be rigidity in one or more limbs, and the head may be bent backwards, or be permanently inclined to one side. Spasm is apt, after a time, to alternate with paralysis, or the latter may be gradually or abruptly established. In some cases the paralysis may come and go; in others, a limb may be paralysed, whilst its homologue is the seat of violent convulsions. The characteristics of this second stage are generally prostration, convulsive movements, gradually developing coma and total paralysis, motorial and sensory, a thready pulse, and an irregular, suspirious respiration.

Stage Third.—The collapse is now complete, and the coma profound. The pupils are widely dilated, and are insensible to light, the eyes are half-open, the face sunk and ghastly, the skin cold and clammy. The sphincters relax, the urine and faeces are passed involuntarily, and the pulse becomes frequent again, indeed more so than before; it is small, and filiform, uncountable; the breathing is stertorous, and the patient at last dies in a state of complete coma.

Acute Meningitis in old persons, Dr. Machlachlan asserts, seldom occurs suddenly, and rarely exhibits the acute symptoms of Meningitis which affects persons of middle age, or of a younger period of life. It commences insidiously, and without premonitory rigors; it may exist some days without the most experienced eye detecting it. The pulse is natural, the tongue clean, the bowels regular, and there is little or no vascular excitement local or general. The temper is peevish and irritable, with more or less confusion of thought, inattention, and forgetfulness. The patient makes strange mistakes, takes possession of another's bed, uses the spittoon instead of the chamberpot. When addressed his replies are rational, but there is a peculiarity in his manner and expression of countenance, an apparent slowness of comprehension, and a vacancy of eye. The appetite meanwhile is normal, and then there is no feverish reaction. Yet there is great restlessness, unsteady gait, a trembling hand when the patient lifts anything to his mouth. After from twelve to sixty-two hours there comes on slight feverish reaction, expressed by increase of temperature only, and not by flushing of face
or increase of pulse. Next, wandering, low delirium, and incessant talking become a frequent and characteristic symptom. Maniacal excitement is uncommon, reverie generally passing into coma constitutes the rule. Headache is not a permanent symptom. The patient moans, but never complains. Unless the patient is pointedly asked about headache, there is never any allusion made to it, or to tinnitus aurium. Dr. Machlachlan takes especial notice of this absence of headache, for even in the most acute pus-forming or false-membrane-forming Meningitis, headache may be entirely absent from the beginning. The eyes are suffused, the pupils slightly contracted, or natural. Knitting of the eyebrows, intolerance of light, acuteness of hearing, and vomiting, are comparatively rare in the aged. The only objective evidence of increased vascular action within the cranium may consist of a hotter scalp than natural, and suffusion and injection of the eyes. There is great thirst usually, the patient will drink freely when liquids are offered to him, but he will seldom ask for drink, whilst he is very apt to refuse all food. In the worst cases, nervous twitchings and convulsions are observed, and these symptoms may be induced when otherwise absent, by raising the patient in bed. When coma is present, slight convulsions of the limbs may be present. The general aspect of the senile meningitis resembles typhus fever rather than Meningitis. The dryness and brownness of the tongue, the muttering delirium, excessive prostration, injection of the conjunctivæ and heat of scalp, equally belong to either affection; but in Meningitis the livid hue of the surface, and the mulberry rash characteristic of typhus, are wanting, whilst the diffused heat of skin of the latter disease is absent, or limited to the forehead and scalp in Meningitis.

Cerebral complications are sometimes apt to arise in the course of an attack of acute articular rheumatism. Of these, an affection resembling Meningitis seems by far the most frequent. In his work on "Diseases of the Brain," Abercrombie relates a few instances of this variety of the affection in a chapter headed, "A dangerous modification of Meningitis, which shows only increased vascularity." In France, where the affection seems to be more common than here, the subject has been very much discussed of late years, and has given rise to a good many publications. So far back as 1835, however, Dr. Watson had called attention to these head complications, which he ascribed to a disturbance of the cerebral circulation, arising from the cardiac disease, which so often supervenes in the course of acute articular rheumatism, and which he stated to denote inflammatory condition of the brain or its membranes.

There is no doubt that cases of rheumatic fever, have occurred in which, from the character of the symptoms, the existence of Meningitis has been diagnosed, whilst post-mortem examination disclosed no such affection. Several such cases are mentioned by Dr. Fuller, in his work on Rheumatism, pp. 303, 304.

The invasion of the disease is, as a rule, very sudden; mostly appearing in the middle of the night. There may or may not have
been some premonition of the coming complication in the shape of a feeling of anxiety, of terror, of strange forebodings of evil, a fear of impending death, expressed by the patient (Bourdon and Vigla); or, for a few hours before the actual attack, there may have supervened sudden mistiness of vision, as in a case related by Trousseau, in his "Clinique Médicale." As a rule, the disease does not occur at the commencement of the rheumatic attack, but is always preceded by pain and swelling of one or more joints. The invasion itself is characterized by restlessness and jactitation, extreme loquacity, and wild delirium, soon followed by coma, with intervals of muscular twitchings or slight convulsions. In some cases, the delirium is remarkable for the obstinate taciturnity of the patient. The pulse suddenly becomes very frequent, small, and irregular. The respiration is sometimes hurried, and sometimes slow. In the majority of cases, the swelling of the joints goes down, the redness disappears, and the cerebral symptoms seem to be attributable to a real metastasis. In some cases, however, the articular disease persists undisturbed. As to the pain in the joints, it is no longer complained of; but this is no proof that it has ceased, it merely shows that the intellect is so affected that it no longer is conscious of pain, or at least no longer takes cognizance of it. One of the most distinctive features of this form of Meningitis is the absence of headache and the absence of vomiting; two symptoms which are so prominent in simple acute Meningitis. In the latter affection, the course of the disease is generally rapid, but its rapidity is much less than that of Rheumatic Meningitis. The patient may die in a few hours; more often from two to five days. If he lives beyond that time, the probability is that he will escape; and this prognosis will be all the more certain if the swelling, pain, and redness of the joints again make their appearance. Recovery, however, is rare, but when it does occur, convalescence sets in rapidly. In some cases the affection terminates in insanity, but the rule is, that death takes place; according to Vigla,* thirty out of thirty-nine cases terminated fatally.

The causes of this peculiar complication of acute articular rheumatism are very obscure. It is said to occur more frequently in cold weather, in the cold months of the year; and there is no doubt that exposure to cold is often an exciting cause. Vigla's assertion that patients who perspire very profusely, and who show confluent sudamina, are more liable to the disease than others who perspire less and have few sudamina, can be easily explained by the greater liability of the former category of patients to catching cold. The disease has been attributed to the perturbing influence of certain methods of treatment. Repeated blood-letting has, by some, been regarded as the cause of the disease, on account of its weakening the system and causing a preponderance of the amount of fibrine over the other constituents of the blood (Beau and Briquet). Others, on the contrary, have ascribed it to the

* Actes de la Société Médicale des Hôpitaux de Paris, 1855, Troisième fascicule, p. 36.
large doses of quinine which, in France particularly, are administered in acute rheumatism. The well-known influence, they say, of quinine in large doses, in producing tinnitus aurium, giddiness, and deafness, explains how its administration may, in acute rheumatism, render the brain liable to be affected by the rheumatic poison circulating in the blood. This influence of quinine in the causation of Rheumatic Meningitis is far from being proved, and Trousseau denies it emphatically. This author cites a case of Dr. Beau in which the symptoms of Meningitis began to show themselves, after the commencement of the quinine treatment, when small doses only of the drug had been given, while it completely disappeared on continuing the treatment, and giving larger doses of quinine.

According to Trousseau, habitual excess in drinking is the chief cause predisposing to this affection, and also an hereditary tendency to neurotic affections of any kind, and chiefly the various forms of insanity. The post-mortem appearances found in such cases are generally a considerable injection of the membranes of the brain, and in some cases sub-arachnoid effusions of serosity are met with; in very rare ones, pus has been found over the hemispheres, as in three cases by Watson.* Trousseau regards the affection as a neurosis, and totally discards the opinion that it is really constituted by an inflammatory condition of the meninges.

Meningitis occurs also in individuals suffering from tertiary syphilis; for just in the same way as nodes and gummy tumours form under the periosteum, in different parts accessible to view, similar deposits are found in the substance of the dura-mater. In some cases, the membrane is not inflamed in the vicinity of these growths, but in others, the dura-mater is thickened, and adherent to the brain, while itself participates in its superficial layer, in the chronic inflammation.

—The symptoms indicating the presence of such deposits are intense and constant cephalalgia, with nocturnal exacerbations; in some cases with convulsions, obtuseness of the intellectual faculties, and sometimes paralysis. The previous history of the patient, the peculiar sallowness of his complexion, and the presence in many cases of periosteal nodes either on the head itself, or on the bones of the leg sufficiently attest the nature of the case. In less patent cases, the history of the patient will often decide its character. According to Robin and Lebert, these deposits can be recognized to be of syphilitic origin by the characters which they invariably present, and the following is a description of their microscopical structure as given by Robin.†

First.—They consist of an amorphous, transparent, greyish, granular blastema.

Second.—This blastema is traversed in spots by lamellar fibres which lie deeply in it, and are often difficult to see, and which are ac-

† In Zambaco, Affections Nerveuses Syphilitiques, p. 60.
SIMPLE MENINGITIS.

compained with fusiform, fibro-plastic bodies, not numerous on the whole.

Third.—In the portions that are whitish, the amorphous blastema is scattered over with a certain number of fat granules, and some drops of oil.

Fourth.—The most abundant elements of the tissue are cytoblasts, which make up four-fifths of the whole. They are uniformly distributed in the amorphous blastema, and between the fibres of the lamellar tissue; they are separated from one another by a substance which scarcely equals their own width. From their number, and their mode of distribution, they make the blastema look of a remarkable uniform composition. Free nuclei are found in great abundance. A few cells are also met with, with pale, transparent, finely granular bodies; they are almost all spherical in shape, some are ovoid, a few angular: the nuclei have a distinct and generally dark contour. They have no nucleolus.

Fifth.—A few rare embryo-plastic elements.

Sixth.—A very few globules of pus.

Treatment consists in the administration of large doses of Iodide of potassium, of mercurial Baths, or when pain and sleeplessness are constant, of calomel and opium at night, with salines and Iodide of potassium during the day.

Inflammation of the Dura-Mater is exceedingly rare, as at idiopathic affection, and generally comes under the cognizance of the surgeon as the result of a blow or a fall on the head. Abercrombie gives one case of spontaneous inflammation of the membrane which had come under his own observation, but even then, the disease had spread to the arachnoid. Inflammation of the dura-mater is apt to supervene in cases of chronic otorrhoea, an affection which frequently sets in after Scarlatina, and sometimes also after Measles and Variola. There is at first merely a thick muco-purulent discharge from the ear, with some tenderness about the mastoid process, and this goes on for a long time, when suddenly the patient becomes dull and drowsy, complains of intense pain in the head, he then becomes delirious, and lastly passes into a state of coma. After death, the petrous portion of the temporal bone is found carious and softened, and the dura-mater overlying it is seen to be detached, inflamed, and generally bathed in pus.

The same series of phenomena may also occur in cases of chronic disease of the ethmoid bone, or inflammation may spread to the dura-mater from the membrane lining the cavity of the orbit in cases of wounds of the eyeball or fractures of the orbit.

The symptoms of the meningeal complication are well marked: there is considerable rigor, recurring in paroxysms, followed by high fever, and so marked are the intermissions that the disease simulates an attack of Ague. Headache is complained of, and the discharge of matter from the ear does not give ease. Vomiting is often present,
together with hyperæsthesia of the retina. There may be slight convulsions, but these are never general, and never so marked and so violent, as in cases of pure meningitis. When there is inflammation of the sinuses in the head, which are formed by duplicatures of the dura-mater, secondary abscesses show themselves in distant and various parts of the body, in the joints of the big toe, the knee, the hip, the wrist, &c. The anguish aspect of the symptoms in such cases is extremely marked: there are strong rigors, followed by heat and clammy perspiration.

The treatment should have for its object to prevent, or at least to limit, the extension of the inflammation, by the application of leeches to the mastoid process, as soon as it is found to be tender, and subsequently by the use of blisters. The ear should be carefully syringed with warm water, and the pus allowed a free escape. When there can be no doubt that the meninges are attacked, the treatment recommended in Meningitis should at once be adopted. When secondary pyæmic abscesses have formed, the treatment should be of a stimulating character, combining the administration of wine and strong nourishing broths, with the use of bark and acids, quinine and iron, &c.

Instances of recovery have been recorded in cases when head symptoms have pointed to an extension of disease from the internal ear to the dura-mater, and Abercrombie has related a case of a young lady, who after the usual symptoms lay for three or four days in a state of perfect coma. Her medical attendants thought her condition utterly hopeless, and continued to visit her as a matter of form. One day, however, they were agreeably surprised to find her sitting up and free from complaint; a copious discharge of matter had taken place from the ear with immediate relief, and she subsequently perfectly recovered.

**Progress, Duration, and Termination of Acute Cerebral Meningitis.**—The progress of the disease is always continuous; there may be slight remissions, but never those intermissions which form such a remarkable feature of tubercular Meningitis, during which the apparent improvement is so great as to mislead the inexperienced into the belief that the patient is getting well.

The duration of the complaint is extremely variable. It has been known to be fatal in thirty-six hours (Rilliet and Barthez), but as a rule, death only follows about the end of the first week, although it may take place at the end of the second, third, and even fourth week.

The termination of the disease is generally in death: very few cases recover, and only when active treatment has been employed at the very outset. It is doubtful whether any acute cases ever pass into the chronic form.

**Pathological Anatomy.**—The post-mortem appearances necessarily vary according to the stage of the disease, in which death occurred. Thus, there may be only intense redness from increased vascularity of the membranes, which are also remarkably dry; or, if the disease has
SIMPLE MENINGITIS.

365

lasted a few days, there may be fluid effused on the free surface of the arachnoid, in the interior of its sac, and in the meshes of the pia-mater. The effusion may be serous, sero-purulent, or entirely purulent. It is rarely abundant enough to produce a distension and prominence of the anterior fontanelle, although a case is related by Abercrombie * in which "at an early period of the complaint, there was observed a remarkable prominence of the anterior fontanelle; in the second week this increased considerably; and in the third week it was elevated into a distinct circumscribed tumour, which was soft and fluctuating, and pressure upon it occasioned convulsion. It was opened by a small puncture, and discharged at first some purulent matter, afterwards bloody serum. After death the opening which had been made through the fontanelle, was found to lead to a deposition of thick flocculent matter mixed with pus, between the dura-mater and arachnoid, and covering the surface of the brain to a considerable extent.

When death takes place at the end of the first week, the pus is no longer liquid; its more fluid portion has been absorbed, and false membranes of a bright yellow colour are now found, which are not yet adherent to the arachnoid. The pus infiltrates the meshes of the pia-mater, and dips between the convolutions. The concrete pus is found in greatest abundance around the larger blood-vessels and in the sulci between the convolutions of the upper and lateral portions of the brain. Sometimes, as in a case detailed by Rilliet,† one hemisphere may be seen covered with pus or false membranes, whilst the pia mater on the opposite side is merely infiltrated with serosity. The brain, in uncomplicated Meningitis, is not affected, it is generally of firm consistency, and sometimes even more so than usual. If death occurred at an early period of the complaint, between the second and fifth day for instance, the grey and white substances present scarcely any traces of injection. After that time, they may still be perfectly healthy, although in the majority of instances, the grey substance is of a somewhat pinkish hue, whilst the cut surface of the white matter shows numerous red points. The whole mass of the brain is always firm, but the peripheral layer of the convolutions may be softened, and when stripped off, the pia-mater which adheres to it, carries away some portions of it. The longer the duration of the disease, the greater the risk of this complication, although there may be exceptions to this rule. In very young children, according to Rilliet, the whole mass of the brain is sometimes soft throughout, and he ascribes this softening to œdema of the brain. The lateral ventricles may be found empty, or they may contain transparent serosity, or even pus, and in rare cases, false membranes. According to Andral (Clinique Médicale, vol. v. p. 140) the presence of serosity should not be regarded as the result of a morbid process,

* Abercrombie: Diseases of the Brain, p. 57.
† Rilliet: De la Ménigite Franche chez les Enfants. Archives Générales de Médecine, 1846, vol. xii.
unless the quantity amount to more than one ounce of fluid in each lateral ventricle.

**Etiology.**—A. Predisposing causes:—

First,—Age.—According to Guersant (Dictionnaire de Médecine, art. Méningite) simple acute Meningitis may occur in the foetus in utero, and is pretty frequent in new-born infants. After the age of two up to fourteen, it becomes rare, and yields in frequency to Tubercular Meningitis, the two being then in the proportion of two of the former to twelve of the latter. After fourteen, it again increases in frequency, and particularly attacks individuals whose ages range from sixteen to forty-five.

Second,—Sex.—It is considerably more frequent in male adults than in women; according to Parent-Duchâtelet and Martinet, in the proportion of three males to one female.

Third.—Those trades or occupations which expose the individual to atmospheric changes seem to predispose to the disease. Thus masons, carpenters, soldiers, &c. seem to be more liable to it than other men.

Fourth.—The sanguine temperament, a short thick neck, hypertrophy of the heart, a very irritable temper, are said also to predispose to the disease, as well as the abuse of alcoholic liquors, excessive grief, and mental work.

**Exciting Causes.**—The most common are blows on the head, falls, and concussions, &c.; and more frequently exposure to a hot sun in tropical countries. The sudden disappearance of a chronic eruption about the scalp, e. g. chronic eczema or Impetigo has been known to be followed by acute Meningitis; but this cause is not so frequent as it has been held by some authors.

**Diagnosis.**—It is extremely difficult to distinguish Acute Meningitis from acute Cerebritis—as the two affections so frequently coexist; inflammation of the membranes having a tendency to spread to the substance of the brain, or the reverse obtaining. In simple Cerebritis, however, uncomplicated with Meningitis, the excitement is not so marked, the delirium is not of the same wild, fierce character, the pulse either does not rise above its natural standard, or falls below it, even down to fifty and sixty; it is, besides, irregular and varies considerably in its rate of frequency. There is also tonic rigidity of one or more limbs, followed by paralysis, which is permanent. In every case, however, the limitation of the inflammation can at best be merely suspected.

From Delirium Tremens, Acute Meningitis may be distinguished by the absence of headache in the former affection, the peculiar trembling, the hallucinations and spectral illusions and fears of the patient, the characters of the delirium, and the abundant, clammy perspiration. The previous history of the patient, besides, usually tells a long story of inebriation.
**SIMPLE MENINGITIS.**

*Typhoid Fever* may be separated from Acute Meningitis by the headache being less intense, by the frequency of the pulse, the presence of diarrhoea, the infrequency of vomiting, if at all present, the gurgling in the iliac fossa, and abdominal tenderness, the leaden tint of the countenance, and after the fifth day of the disease, by the characteristic rose spots.

The points of distinction between the simple and the Tubercular forms of Meningitis will be given when treating of the latter affection.

**TREATMENT.**—The treatment of Acute Meningitis is only successful when employed very early in the disease, and carried out with energy. It resolves itself into three great remedial measures; first, blood-letting; second, hard purging; third, application of cold water to the head.

**First, blood-letting.** The patient is to be bled in the sitting posture, from a large opening in a vein in the arm, and continued until syncope is induced. The bleeding is to be repeated as often as the symptoms require it, or to be followed by the application of leeches behind the ears and to the temples. Continental practitioners often prefer bleeding from the dorsal vein of the foot to opening a vein at the bend of the elbow. According to Guersant, in very irritable individuals who are very sensitive to pain, especially in very young children, the application of leeches to the head increases the restlessness and the headache, and he therefore recommends that the leeches should in such cases be applied round the arms or about the ankles.

When it is not considered advisable to repeat the bleeding, compression of the common carotids in the neck, as originally suggested by Dr. Bland (of Beaucaire),* might be had recourse to, so as to cut off temporarily the supply of blood to the head.

The application of leeches to the interior of the nostrils, or scarifying the membrane with a lancet, is a favourite practice with some of the German physicians, and must directly relieve the circulation in the head on account of the inosculations between the vessels which ramify in the pituitary membrane and those at the base of the brain.

**Purgatives.**—Active purging possesses considerable efficacy in the early stage of the disease, and materially aids bleeding in producing its full effects. Calomel, jalap, and scammony are the purgatives usually selected, but Croton oil seems by far the best, from the case with which it may be administered, even to children, and the certainty and rapidity of its action.

**Mercury.**—Apart from its purgative effects, it is a most valuable remedy in Meningitis. It should be administered in small and frequently repeated doses, so as to bring the system under its influence quickly; and this is best effected by combining, with its internal administration, the use of mercurial inunctions in the groin and axilla.

* Bibliothèque Médicale, vol. i.ii. See also Valleix, Guide du Médecin praticien vol. ii. p. 49.
The application to the head of cold, in its various forms, should never be neglected. There is no remedy so effectual in lowering the heat of the head, calming the headache, and subduing the violence of the delirium. Simple compresses, kept wet with cold water, are the least useful form of using cold, as they are soon heated and become dry, and the alternation of heat and cold thus produced, might be injurious by attracting more blood to the head. A bladder, containing pounded ice, or a mixture of common salt and ice, is an excellent mode of applying cold, because of the facility with which it adapts itself to the shape of the head. The most effectual method, however, is *irrigation*, i.e. allowing a small stream of water to run on the head from a vessel placed a little above it. The effect of this is almost magical, but it should be used with great caution, particularly in children and aged persons, so that its sedative influence might not be too powerful. Previous to using any applications on the head the hair should be cut close or shaved, and this simple measure is sometimes attended with great relief to the patient. Simultaneously with these applications revulsives should also be employed at the opposite extremity of the body by wrapping up the calves of the legs in mustard poultices, or in blankets wrung out of hot water and sprinkled with turpentine.

When the disease has passed into the third stage, that of coma, the above treatment is no longer admissible. Blisters applied to the nape of the neck and behind the ears, are exceedingly useful; and if the coma be very profound, a cap of blistering ointment applied over the whole skull has been known to rouse the patient. Flying blisters, applied in rapid succession to the inner aspect of the thighs, the calves of the legs, or mustard poultices even, are then useful also to rouse the system. When collapse has set in, mercury and purgatives should, of course, be discontinued, and stimulants, ammonia, and bark had recourse to. The bladder should be frequently examined to prevent the accumulation of urine and its consequent evils.

Dict.—The diet, in the first stages, should be low; no solid food is to be given.

In the third stage, however, strong broths given in small quantities repeatedly, and wine become essential.

The room in which the patient lies should be kept cool and dark, and well-ventilated, and free from the slightest noise.

Sometimes after the acute stage of the disease has passed, and convalescence has begun, the delirium is apt to return.

The practitioner should carefully guard against the error of mistaking this condition for one of recrudescence; it is due to exhaustion, and as such, requires a judicious stimulating plan of treatment. It may be known by the coldness and pallor of the surface, and the weak compressible state of the pulse.

When occurring in the course of acute rheumatism prophylactic measures should always be adopted, such as the avoidance of cold, clothing the patient in flannel, and carefully watching the condition...
of the joints: if there be retrocession of the swelling and redness and pain in the joints, while the patient becomes restless and loquacious, we must try and bring back the rheumatism to the joints by wrapping them up in mustard poultices or applying blisters. Opium and mustard have been recommended, and Trousseau declares that he has cured three patients by the combined administration of these drugs, although he adds that two others got well without any active treatment having been employed. In any case, the alkaline treatment for rheumatism should be continued, and careful nursing and the administration of unstimulating food adopted.

**Chronic Meningitis.**—This is a very rare affection, and it is generally recognised after death only from the pathological appearances met with in the meninges—namely, thickening and opacity of the arachnoid, cellular adhesions between it and the pia-mater, development along the falx cerebri of the so-called glandulae Pacchioni, which from their absence in infancy and youth are generally regarded as evidences of chronic meningeal irritation. In some cases, plates of osseous tissue have been found in the membranes; whilst during life, the symptoms presented by the patient did not point to any mischief in the head.

Troublesome headache, a disposition to somnolency, sometimes convulsive twitchings, and in children, vomiting, are regarded as symptoms which should excite suspicion of the existence of chronic Meningitis. Of that form of the affection—which is complicated with chronic inflammation of the superficial layer of the cortical substance of the brain, and is symptomatically characterised by lofty ideas, hallucinations, paroxysms of maniacal excitement and embarrassment of speech, followed by gradual general paralysis of motion, sensibility being scarcely affected, and terminating in idiocy—we have nothing to say here, as the affection is always treated of in conjunction with insanity.

Although chronic Meningitis in middle age and in early life is of rare occurrence, it is not so rare in old age. Concerning it Machlachlan observes, "The disease may be of a chronic nature, ab initio; chronic in regard to the subdued and insidious nature of its symptoms, while at the same time it pursues a strictly chronic course, seemingly, now and then existing one or two years, and never following an acute attack of the disease. It is not an unfrequent result of albuminuria, and repeated attacks of delirium tremens, or it follows gout and rheumatism. Chronic Meningitis in the aged is almost uniformly accompanied with great impairment of the mental faculties, frequently with thickness of speech, and paralytic weakness of the lower extremities, the gait being tottering and feeble. The energies of the system are reduced; all movements of the limbs are performed awkwardly, slowly, and with uncertainty. The appetite remains good; but digestion is slow, bowels are inactive, and the various excretions vitiated. Vertigo, singing in the ears, marked loss of memory,
slowness of comprehension, periodical fits of passion, and occasional attacks of headache, with or without signs of high vascular excitement, are frequently observed. Sooner or later the invalid takes to his bed reluctantly. Then he lies uncomplaining, vegetating, and gradually sinking, dying often in consequence of sloughs on the nates.

TREATMENT.—The diagnosis of this affection being so uncertain and obscure, it is clear that little is known regarding the mode of treating it. If the symptoms in the least show a tendency to assume the acute form, the application of leeches behind the ears, cupping the nape of the neck, and administration for a short time of small doses of a mild mercurial would be called for. Otherwise the use of repeated blisters applied to the nape of the neck, and the internal administration of iodide of potassium, and occasional purgatives, seem to be the most rational treatment that can be employed. In the form occurring in old age, cold lotion to the head, an occasional brisk purge followed up by an enema, are most advisable. The condition of the bladder must be frequently examined, and the catheter employed should retention arise; when, on the contrary, there is dribbling, a proper apparatus must be worn. Good nursing, cleanliness, the hydrostatic bed, are also essential. In the later stages of the disease, when the vital energies begin to part and fail, wine will be essential, but until then the treatment should be strictly antiphlogistic; the patient avoiding also all mental excitement, and if not secluded, he should be kept tranquil both in body and mind.

Secondary Meningitis.—This affection sometimes shows itself in the course of one of the eruptive, or exanthematous disorders, as typhoid fever, measles, scarlatina, and variola.

When Meningitis occurs in the course of an eruptive fever, some of its ordinary symptoms may either fail entirely, or be masked by those of the primary disease. Thus, the intense headache of acute primary Meningitis may be absent, or it may be slight only, and there may be no vomiting. The invasion of the super-added disease may, however, be recognized by a sudden slackening and irregularity of the pulse and respiration, by the pallor and anxious look of the face, and the extreme jactitation which ushers in the delirium.
By acute tuberculosis we mean that disease which is attended necessarily by the formation of miliary tubercle. Inflammation of the brain and its membranes, occurring as a consequence of the progress of acute tuberculosis, is called Tubercular Meningitis. The meningitis, then, is merely a fragment of a general disease; but, inasmuch as from the moment that the brain is distinctly involved the symptoms of the general disease are overpowered by the effects of the disorganisation of the brain, which goes on rapidly, attention becomes concentrated upon the local disease, so that we almost forget the tuberculosis in the encephalo-meningitis.

**Causes.**—The etiology obviously includes the doctrine of the causation of the tubercular diathesis, the acute tuberculosis, and the meningitis; but the known causes are not so numerous as to call for much method in their arrangement.

Be the case as it may with regard to the adult, I think that most physicians will agree that the tubercular diathesis in the child is strongly hereditary. To speak more particularly; it will be found that a large majority of children attacked by Tubercular Meningitis come of families in which there are, or have been, sundry manifestations of a tendency to tubercular diseases. Yet in many cases no tendency of the kind can be discovered.

Nor will the special build and temperament, which are characteristic of the diathesis, be present in all cases of Tubercular Meningitis, even among children.

Neglected hygienics are powerful incitements of acute tuberculosis. Injuries to the head, so far as is known, do not markedly determine tuberculosis upon the brain.

The influence of sex, season, or social position upon the occurrence of Tubercular Meningitis is quite insignificant.

Tubercular Meningitis may set in at any age. No doubt the disease is more common before puberty than afterwards; but it is, at present, impossible to procure numerical proof of the fact, and this on account of the comparative exclusion of children from the general hospitals into which adults are admitted. During the four years preceding April, 1866, thirty-six cases of Tubercular Meningitis were admitted.
into the Hospital for Sick Children, London, an institution making up from thirty-one to fifty medical beds: we may safely affirm that nothing like that number of cases would have been admitted into an adult hospital of the same size in the same time. In a spirit of reaction from old opinions, there has been a tendency of late years to underrate the comparative frequency of Tubercular Meningitis in the child. A fault of most tabular statements, which have been published to show the ages of patients dead of this disease, is that they encourage the notion that Tubercular Meningitis is much less common under two years of age than is really the case. It is sufficient to know that the disease does occur within the first two or three months after birth. The following is the table drawn up by Guersant (Dict. Méd. en 30, t. xix); it is the least open to objection of any table that I know:

Symptoms.—The symptoms of Tubercular Meningitis sometimes break in suddenly upon what has seemed to be, so far, a state of perfect health; sometimes they are preceded by several weeks or months of indistinct poorliness: both groups of cases (seeing that in both the sure and certain symptoms of distinct disease are cerebral from the very first) may be classed together under the head of Primary Tubercular Meningitis. But, on the other hand, Tubercular Meningitis sometimes attacks a person who has already exhibited symptoms and signs, either of acute general tuberculosis, or of local tuberculosis, acute or chronic: this may be called Secondary Tubercular Meningitis. Ordinarily its existence is apt to be overlooked, unless its special symptoms have been watched for; sometimes, indeed, the disease is wholly latent, and discovered post mortem only.

I. Primary Tubercular Meningitis:
1. With premonitory symptoms.
2. Without them.

II. Secondary Tubercular Meningitis, preceded by manifestations of
1. General Tuberculosis.
2. Local Tuberculosis: i. cerebral;* ii. thoracic; iii. abdominal.

The primary form of the disease with premonitory symptoms is the typical form.

* i.e. Tubercular tumours of the brain which have produced symptoms.
PRIMARY TUBERCULAR MENINGITIS IN THE CHILD.

1. Premonitory Symptoms.

Their Character.—i. Loss of flesh is the most constant precursor; indeed, is almost constant; often the first, sometimes the only symptom: the child’s face being very much spared, it is when the nurse comes to undress him that she finds the limbs to be losing their roundness, and the flesh flabby to the feel. This loss of flesh mostly proceeds continuously; sometimes, however, the child will seem to pick up for a time and afterwards begin to waste again. ii. Loss of colour concurs: it is sometimes masked by a false colour in the cheeks, due to permanently dilated capillaries; it may be only now and then that this colour leaves the cheeks, and then the real paleness of the child is obvious. iii. The child is drowsy by day and restless at night; he is easily tired, and in the midst of play will lie down on the floor and fall asleep for a short time; at night he grinds his teeth, sleeps with his eyes half open, starts, and cries out; he is sad, fretful, peevish, taciturn, and wants to be let alone: if for any reason a young child has been put to bed for a day or two, he will not take to his feet again. iv. Headache is frequently absent, rarely a prominent symptom, but mostly present to a certain degree: very young children will be observed to put their hand to their head, and to toss their head on the pillow; older children will say that their head aches, and this especially after some exertion of mind or body; a child will go to school and come home complaining of his head: the headache is rarely severe, and mostly frontal; a strong light increases it. v. Feverishness is not always present; when it is present, it is noticed chiefly in the evening. I do not myself possess any thermometrical observations made during this period, nor do I know of any that have been published.* vi. Loss of appetite is common; vomiting uncommon; the bowels are confined, or relaxed, or quite regular in action.

These symptoms are grouped in every manner possible; any of them may be absent, and, how many soever be present, they do not justify more than a fear lest the condition should terminate in Tubercular Meningitis.† It may be possible, in time to come, to distinguish between the prodromata due to tuberculosis, and those due to a state which merely affords an opportunity to the tubercular diathesis. It is highly probable that the remittent feverishness which attends acute tuberculosis might sometimes yield the means of a distinction: this is certain, that the most careful mother will often fail to observe any feverishness before the day of invasion, even though she have been disquieted for weeks or months by her child’s steady loss of flesh and strength. As the invasion approaches, all the premonitory

* The reader will bear in mind that primary tubercular meningitis only is under consideration.

† Refer to section on Diagnosis.
symptoms become more pronounced. The poorliness induced by the acute specific or other diseases often passes uninterruptedly into the premonitory period of Tubercular Meningitis. Measles (so far as I have seen) is the most common antecedent, hooping-cough next, occasionally an attack of diarrheoa and vomiting, bad sore throat, or hip disease.

The Duration of this period is different in different cases. Sometimes, as mentioned before, there are no prodromata at all.* There are all grades between this extreme and the other in which a child loses flesh for four, six, or even more months before the invasion. One or two months may be regarded the average; sometimes the prodromata last two or three weeks only. Again, in some cases, the precursory stage is interrupted by a temporary improvement in the health of the child.

2. Invasion.

By the invasion of Tubercular Meningitis, I mean the period at which there occur such new symptoms as enable us to pass from the uncertainties of the prodromal stage, and to declare most positively that from this date, at all events, the child has sickened with hydrocephalus. The invasion symptoms are the first which make the friends of the child think him dangerously ill; the poor, as a rule, only now begin to seek advice.

Character of Symptoms.—(1) Vomiting is by far the most common special invasion symptom. In the majority of cases the frequent repetition of the vomiting makes it seem to be the most important symptom of the onset; but sometimes, although serving to mark the invasion as well as ever, the sickness is subsidiary in urgency to the other symptoms. In the former case, the child may vomit incessantly with and without taking food; in the latter, the child may be sick only once or twice. (2) Convulsions are the next most frequent (though much less frequent) special symptom of the invasion; they, like the vomiting, may be repeated several times or not. Sometimes the attack is quite epileptiform, sudden, with complete unconsciousness, and yet without convulsive movements. It will give some notion of the comparative frequency of the different modes of invasion to mention that, out of twenty-five cases in which the invasion symptoms were carefully ascertained, vomiting without convulsions occurred in nineteen; vomiting followed by convulsions in one; convulsions without vomiting in two; several attacks of general rigidity, succeeded by vomiting on the third day, in one; in one an attack of temporary unconsciousness (epileptiform), followed by vomiting; and

• It may afford some notion of the frequency with which the prodromata occur to mention that, out of twenty-six cases of primary tubercular meningitis (the diagnosis confirmed by a post-mortem examination in all), there were only two in which premonitory symptoms had not been noticed. That sometimes the prodromal stage is absent, or so slight as to be unnoticed, even in children carefully looked after, I have no doubt.
in the remaining case the invasion was marked by a notable and comparatively sudden increase in the severity of the premonitory symptoms (headache, drowsiness, loss of flesh), without vomiting or any motorial symptoms. The most important concomitant symptoms of the invasion are: the first occurrence, or the increase of headache, or of the pyrexia, or of drowsiness; the coexistence of constipation is a rule with an occasional exception; there is often a change in the temper of the child, or some odd unreasonable behaviour; the character becomes morose, irascible, and obstinate.

**Period of Occurrence.**—From seven to twenty-one days elapse between the invasion and death; the average is fourteen days. "When the Meningitis sets in suddenly without prodromata, its duration is from twenty to thirty days, rarely less, provided that no complication modify the course of the disease" (Rilliet, iii. 487)—a very necessary qualification.*

3. The Established Disease.

Dr. Robert Whytt’s first stage of dropsy of the brain includes the prodromata and the invasion of the disease. The subsequent course of the disease he divides into two stages, the one being an earlier period during which the pulse is infrequent, and the other a later period of frequent pulse. This division of Whytt’s is true to nature, but the pulse is a fallible criterion. In order to recognise that a patient is in one or other stage of the disease, the physician must look at the symptoms in a comprehensive spirit. There is an earlier period (the second of Whytt) in which the brain may be regarded as reacting under or against the disease: the symptoms are sthenic, e.g. headache, delirium, exalted sensibility, infrequency of the pulse, consciousness being retained: the whole condition answering to the augmentum morbi infra statum of the schools. The disease goes on to produce destruction of the brain; the symptoms are simply the result of a steadily increasing paresis of the animal functions: stupor, insensibility, paralysis, frequency of the pulse—all indicate the augmentum supra statum, or the third period of Whytt. To repeat: the observer must not narrow his view to the variations of a single symptom, or he

* Rilliet thus describes a "slow invasion occurring in the midst of perfect health":—

"The development of the invasion symptoms may be so slow and insidious as to approximate to the characters of the prodromata. In some cases there is remittent or intermittent fever, accompanied by vomiting and constipation, with or without headache, and lasting several weeks. In other cases the child complains of headache, gradually increasing in severity, though only moderately severe at first, accompanied by vomiting, which lasts several days or several weeks. In spite of the headache, and sometimes in spite of the vomiting, the appetite keeps up, the children are not feverish [in the latter class of cases?] and go about as usual. We have seen children, ailing in this way a fortnight, and having already an infrequent, irregular, and unequal pulse, come on foot to consult us, and known them to answer questions perfectly clearly. Yet they sleep badly, are rather oppressed in the day; then, after fifteen or twenty days, or even more, symptoms supervene which declare positively the nature and gravity of the disease. The duration of the disease in such cases is about three or four weeks, sometimes more, even five and forty days or two months, but this is very rare." (Mal. des Enfants, iii. 481, 487.)
will often fail to perceive the stages of Dr. Whytt, or even be inclined to reject them. In the second of the ensuing paragraphs I have noticed the variations of the pulse somewhat minutely, so as to show how little it is to be trusted as a certain sign of the stage of the disease.

(1) Digestive Organs.—i. Vomiting.—As already mentioned, the vomiting of the invasion is ordinarily repeated several times. Sometimes the symptom is very urgent, occurs whether food has been taken or not; and this may be so every day for a week. When once the tendency to vomit has ceased for twenty-four hours, it does not ordinarily recur. ii. Constipation.—In the great majority of cases the bowels are constipated throughout the whole course of the disease; yet sometimes they are spontaneously relaxed throughout; more frequently (especially when hard purging has been part of the treatment of the beginning of the disease) they are relaxed, without the use of drugs, towards the end. The constipation is not often obstinate; it is easy, for the most part, to procure an action of the bowels by common means. iii. Retraction of the walls of the belly is a symptom which will be met with at some time or other in nearly every case: sometimes present for a day or two only, and at no certain period; sometimes present all along. Acute diseases affecting the brain are the only acute diseases of children, which, as a rule, cause great excavation of the belly. iv. The Tongue has no fixed character; it may be moist and clean. Aphthae sometimes occur as death draws nigh.

(2) The Circulation.—i. The Pulse affords symptoms which have been much studied, and with good reason, for they are most important. a. Its frequency is diminished in the earlier and increased in the later part of the disease: this is the rule. The increase mostly sets in during the second week; sometimes much later (e.g. boy, of four years, eighteenth day = 84; 116, 128, 128, 168, on successive days, death on twenty-third), or earlier (e.g. girl, eight years, sixth day = 140). Sometimes the increase occurs only three or four days, sometimes eight or ten days, before death. Sometimes the increase takes place suddenly (e.g. boy, two years four months, seventh day = 72; eighth day = 164), sometimes gradually. After the pulse has been very frequent, it may again become comparatively infrequent (e.g. girl of one year ten months, eighth day = 162; ninth = 144; tenth = 100; eleventh, day of death = 180). This infrequency may persist and increase up to the day of death (e.g. girl, two years six months, fifteenth day = 120; sixteenth = 140; seventeenth = 76; eighteenth = 70, i.e. day of death): cases of this kind die in a state of algid state unsurpassed in any other disease.* As to the absolute frequency, I have not known the pulse to fall below 64. At the invasion of the disease “the pulse is not much accelerated: 108, 112, 120 at most; sometimes it is even already slackened” (Rilict, iii. 480). The frequency is at all times easily increased by movement of the body.

* Refer to paragraph on Heat of Body.
TUBERCULAR MENINGITIS.

b. Irregularity in the rhythm and inequality in the force of the pulse are two symptoms upon which great stress is laid in the diagnosis of Tubercular Meningitis. They coincide with the period of infrequency; not that an infrequent pulse is irregular at all times, but it will be found so, at least, now and then. During the period of increased frequency the irregularity is less easy to detect, and is probably really less common; yet a pulse of e.g. 170 will sometimes be found distinctly irregular. ii. The modifications in the cutaneous circulation are well displayed in the face. If habitually pale (as it sometimes is from beginning to end of the disease), a flush is easily produced by excitation of any kind—by moving the child, giving him to drink, brushing the hand over the cheek, and so on. Sometimes the flushing is spontaneous: limited to one cheek, or general as regards the head; constant, or alternating with pallor. The highly characteristic facies of acute brain disease* is chiefly effected by the congestion of the face. What is best seen in the face is observed to a less marked degree in the skin of the trunk and limbs; that is, the skin is injected at times. Spontaneous injection is often made evident by the unusually distinct white ring left by the pressure of the end of the stethoscope. As in the face, so in the skin of the trunk and limbs, injection, when not present, may be easily procured: draw the finger across the skin, and, in a few seconds, a red streak will appear along the track of pressure. The peculiarity of the “tache cérébrale” is that it follows a lighter stroke, comes out sooner, is larger, and lasts longer than the red streak, which may be made in the skin of a healthy person. To myself it has often been impossible to get a red streak in cases of Tubercular Meningitis except by an unfairly hard stroke, such as would cause a redness in the skin of any child; and it has so happened also, that, when the tache cérébrale has been sought as an aid to diagnosis, its nice characters of less and more have often been so uncertain as to be useless; and that when a well-marked cerebral streak has been produced, the nature of the disease has been for other reasons abundantly certain. I think it is rare to get a red streak early in Tubercular Meningitis. The flushing of the face and the tache cérébrale are obviously the same phenomenon occurring in different places.

(3) The Respiration also yields symptoms deserving careful study. The frequency is increased, diminished, or at the natural rate. Increased frequency of pulse and respiration sometimes go together, but not always (e.g. boy of five years, P. = 190, R. = 24; day before death). Irregularity and inequality are often very striking in later stages of this as well as of all other acute cerebral diseases of childhood. Sometimes the respiration is irregular only, sometimes unequal only, often both irregular and unequal: the child may remain for many seconds as if he had forgotten to breathe, then follow a few rapid respirations, then another pause, and so on. A careful examination will sometimes be necessary to detect irregular breathing. Sighing expiration

* See paragraph (8).
is particularly common when children become half-insensible from Tubercular Meningitis.

(4) Heat of Body.—The first three or four days of the established disease are attended by what seems to be (judging by the hand) a distinct increase in the heat of the skin. This is followed by a period of low pyrexia, during which the temperature only occasionally exceeds 101°. I do not say that the temperature is not sometimes persistently higher, but I do not happen to possess notes of any cases in which it was so; whilst, on the other hand, for days together the temperature may vary between 96° and 98°. As death approaches (say for about the four days preceding death) cases have seemed to me to group themselves into three classes: in one, the state of moderate fever continues up to the very day of death; in another, the fever greatly increases before death; in a third, the body-heat falls below the standard of health. An example of each class will make this more clear:

The minimum and maximum temperatures of each day are given.

The peculiar variety of ardent fever referred to the second type (the lipryia of Galen) is, perhaps, more common in Tubercular Meningitis than in any other disease.† "Heat of the viscera, as if from fire, but the external parts cold; the extremities—that is to say, the hands and feet—very cold" (Aretæus; De Ac. Morb. Cur. ii. 3). "Pessima in acutis conditio:" and a plain proof that the power of resisting cold and the power of generating heat are distinct. A thermometer in the arm-pit will prevent our being misled by the coolness of the exposed parts. In the third type the algidity involves the viscera themselves; the temperature in the example adduced was taken by means of a thermometer kept permanently in the rectum; and, as the hyperpyrectic cases might deceive the hand applied to the limbs only, so might the state of algidity deceive the eye. The example chosen one hour before her death, when her temperature was 79·8°, her breath cold to the hand, and her pulse imperceptible at the wrist, still kept a little colour in her cheeks, and (except that her eyes were half-open) it would have been impossible for one merely looking at her to have said that she was not a tolerably healthy child calmly asleep. The pulse, as a rule, agrees with the temperature, rising in frequency as the temperature rises, and falling as it falls: no proportion is kept in the amount of the rise and fall. Excessive frequency of pulse may concur with a moderate elevation of temperature; or, reversely, the temperature may be high and the pulse infrequent (e.g. temperature

* One hour and a half before death.  † At very moment of death.  ‡ See article on Scarlet Fever, vol. i. page 342.
103°, pulse 72—a ratio really observed, and such as would serve to clench the diagnosis of acute disease of the brain). Heat of the head greater than of the rest of the body is a symptom far from always observed in the earlier stages of the disease, and still less frequently in the later.

(5) Nervous System.—i. *Headache* concurs with the invasion, or, if present previously, is much increased then. The pain is mostly referred to the top of the frontal bone. The headache is tolerably constant, subject to paroxysmal exacerbations, and lasts until stupor sets in. The temporary increase of headache is sometimes made known by the moaning of the child; sometimes he cries out, “Oh! my head,” or shrieks,* or holds his hands hard on his head; he greatly dislikes any disturbance, for that increases the headache. But it must not be supposed that headache of this severity is present even occasionally in all cases. ii. *Eye Symptoms* are very important. One pupil is often distinctly larger than the other: this state is present at some time or other in every instance of the disease, does not occur at any special period, and is not always constant; thus the inequality in size present in the earlier part of this stage not rarely disappears later on in the disease, in order, it may be, that the relation of size may be reversed for a day or two before death; or, sometimes the variations are much more rapid. Dilatation and sluggish action of the pupils is the rule towards the end of the disease, but the absolute size of the pupils is of small value in diagnosis. Squint is present sooner or later in every case. Hemiopia may occur so early in the disease as to be discoverable. (Trousseau, ii. 236, 237.) Oscillation of the eyeballs, or of one eyeball (the other being fixed), is common in the later period. iii. *Paralysis of the Face,* one eye opened less widely than the other, one nostril being rounder than the other, one corner of the mouth less acted upon by the muscles than the other, one side of the upper lip straightened—these are frequent concomitants of the later period. iv. *Paralysis of the Limbs.*—Quite towards the end of the disease we often observe one or more of the limbs to be unmoved, relaxed or feebly rigid, flexed or extended. v. *Convulsions and Rigidity.*—These have been already mentioned as occasional invasion symptoms. As terminal symptoms they are equally frequent, occurring on the day of death, the child perhaps dying immediately after a convulsion. Yet they are not to be trusted as a sign of impending death, or even of death likely to occur in a day or two. When convulsions have been invasive they do not necessarily recur. The following may be taken as an example of the state of a child in convulsions towards the end of the disease: he lies

* I copy the following particulars relating to the “hydrocephalic cry” from Trousseau (Clin. Méd. 2me édit. vol. ii. 239):—“It is a single, violent cry, resembling the cry of a person suddenly exposed to great danger: the expression of the face is not that of suffering: any period of the disease may be attended by this cry, which may occur every hour, half-hour, or even every five minutes.” Rillic (iii. 500) does not consider this to be either a common or a special symptom—an opinion with which my own experience would lead me to coincide.
unconscious, whole skin injected, eyeballs drawn upwards and to one side, pupils large, one side of face more wrinkled than the other, teeth clenched, limbs rigidly extended—except the hands, the fingers of which are flexed—slight twitching movements of face and limbs, more marked on one side than the other, respiration laboured. As the child comes round the unconsciousness diminishes, pupils become smaller, he is left bathed in sweat. Sometimes the clonic movements are more marked. Sometimes the limbs are relaxed throughout, and the twitchings limited to the face and eyeballs. Permanent feebler spastic rigidity of one or more groups of muscles is common during the latter period: sometimes the rigidity is much stronger. Opisthotonos may be present during the last few days of life; it may be paroxysmal and last only a few minutes, or it may be continuous and last until death. In such cases I have not found any signs of inflammation about the cord or its membranes. Tremulousness of the limbs is very common. A shudder may be often observed to pass through the body from head to foot. Many other niceties of motorial symptoms might have been described: enough has been said to show the infinite variety present in Tubercular Meningitis. vi. Sensation.—Tenderness of the skin can be demonstrated to be present in some cases; it is often very obviously present in the scalp when a barber is employed to shave the head. Pains in the limbs are sometimes complained of early in the disease. Dislike of light is common at the same period. Blindness is difficult of recognition, because occurring late. All these symptoms are sometimes unilateral. vii. Consciousness.—The children soon become somnolent: they lie with their eyes shut or half-shut, reply to questions in a dry short way or by a nod; when raised up in bed they complain much, knit brows, throw head back, and slip down in the bed. They dislike disturbance extremely: will clenched their teeth against food. As the somnolence increases, the children cease to speak, but they will put out their tongue when shaken and pertinaciously asked to do so; they then relapse willingly into their former soporose state. By degrees, or sometimes suddenly, the sopor becomes deeper; but not until near the very end, and not always even then, does the coma become so deep that the child will not withdraw his limbs (provided they are not paralysed or rigid) when pinched, and also give other signs of being discommoded. Inability to swallow accompanies the coma. Retention of urine is sometimes rather an early symptom. The consciousness may be perfect the day before death. The semi-coma may be continuous from the invasion to the end of the disease. Delirium is common, but is not a symptom of much value in diagnosis, prognosis, or treatment.

(6) Physical Signs of tuberculosis of the lungs are not often to be detected in cases which, by reason of their course, are arranged under the head of Primary Tubercular Meningitis. Yet occasionally, and that even when the foregoing pouliness has not been greater than usual, I have detected the signs of a cavity under one or other clavicle. Sonorous rhonchi may be met with, sometimes a little
bubbling; and in exceptional cases, which are, nevertheless, cases of Tubercular Meningitis as opposed to acute tuberculosis, all the physical signs are present of that very fine capillary catarrh which, in children, is nearly always indicative of the co-existence of tubercle or pneumonia. This sign I have observed in Tubercular Meningitis, and in no other disease: namely, the chest heaves equally well on both sides, and yet over a very large part, or even the whole of one side, no respiratory sound is heard by the stethoscope.* In a few hours this sign will have passed away. It is probably due to a slight pulmonary catarrh concurring with the respiratory unconsciousness of the brain disease. When the fontanelle is large, it is mostly distended; when small, the distension cannot be perceived.

(7) Urine.—In the case of a boy, aged four years, in whom it was necessary to employ the catheter, I had an opportunity of examining the urine. The following was the result:

Weight of body—case of Meningitis, 19\(\frac{1}{2}\) lb.

Healthy child, . . . 28 lb.

(8) General Appearance: Summary.—Although the individual symptoms which have been now described are grouped in almost every possible manner in the different actual examples of Tubercular Meningitis which we meet with, yet it may be well to recapitulate the chief matters in what has gone before, and so to arrange them as to form a sort of idea or type of primary tubercular meningitis in the child.

A boy of five years old, in whose parental antecedents there are signs of a tendency to tuberculosis, begins to feel poorly, to lose flesh, and to complain occasionally of his head; he is restless at night; and languid by day; his bowels are rather confined; he is subject to irregular feverish attacks. These symptoms last two months, and then, one day, the child vomits for the first time; during the next three or four days the vomiting is repeated several times; afterwards it ceases; at the same time the fever runs higher, the headache increases, the nights are noisy, the constipation is obstinate. About the time that the vomiting ceases, other symptoms pointing to cerebral disease appear; say, for example, on the sixth day after the first vomiting, he looks thin and pale; skin hot and dry; temperature

* Compare Laennec. Ausc. Méd. 2me édit. i. 147.
100.8° (evening); pulse 84, irregular; respiration 20, regular; tongue dry, red tip, light fur elsewhere; bowels not open; belly natural; converging strabismus of one eye; pupils of middle size, mobile, one larger than the other; he says he has headache, and points to his forehead as its seat; physical signs of chest are negative; tache cérébrale uncertain; the boy is quite rational, moves about in bed, sits up, answers questions, and the expression of his face is not peculiar: the diagnosis rests (and rests surely) on the previous history, the pulse, and the condition of the eyes. On the seventh day he is much the same; belly rather retracted; pulse 108, very irregular; respiration regular; temperature, 100.4° (morning) and 101° (evening). Eighth day: no marked change, rather lower; pulse 112, still irregular; temperatures, morning and evening, 100.2° and 100.6°; all the other symptoms remain unchanged. Ninth day: clearly much worse; consciousness failing; does not cry out; probably can still see; tache cérébrale easily produced; cheeks, habitually pale, easily flush; cannot sit up; no special expression in face; swallows well; pulse, 160, regular, weaker; eyes as before; arms very tremulous; temperatures, 101.2° and 103°. Tenth day: still worse, semi-stupor, cannot be made to speak; eyes only half open; passes excreta under him; lies fidgeting and picking with tremulous hands; pulse, 168, regular; temperatures, 101.3° and 102.4°.Eleventh day: stupor greater; he occasionally moans; whole surface much injected, face and head greatly flushed, dusky; and as the child lies on his back, motionless, with his half-opened and prominent eyes, their corners filled with thick secretion, and the cornea dusty and filmed, he has a look quite characteristic of hydrocephalus; pupils dilated: one eye fixed, and probably blind; swallows pretty well; belly greatly sunken; pulse, 180, regular, very weak; respiration, 15, irregular; temperatures, 101° and 103°. Twelfth day: stupor deeper still; moves limbs of one side feebly; those of the other side are somewhat rigid; swallows badly; pulse so frequent and feeble that it cannot be counted, feet cold; temperatures, 101.5° and 103.6°. The next morning he dies.

Duration.—The duration of primary Tubercular Meningitis with prodromata is from seven to three-and-twenty days. It has been already mentioned, on the authority of Riliet, that when the prodromata are wanting the duration is from twenty to thirty days, and that when the invasion is slow and insidious (page 79) the disease lasts from thirty to fifty, or even sixty days.

Remission in the gravity of certain symptoms is not uncommon in the acute cerebral diseases of children. The direct nervous symptoms are the most variable; the squint, the unequal or dilated pupils, the rigidities, and the somnolence. The variations in the last symptom are the most striking and deceptive, semi-stupor passing away so as to leave the intellect perfectly clear. But when once the physician has satisfied himself of the existence of Meningitis, he should not let his diagnosis be easily shaken. As Riliet acutely observes, "the improvement does not show itself in all the symptoms;" the pulse
remains irregular, it may be, the squint, or inequality of pupils persists, and though the remission should last a day or two, the child will die as surely and as early as if all the symptoms had been continuous.

Termination.—The rule of inevitable death, however, must be qualified, even in Tubercular Meningitis, by the admission that recovery occasionally takes place. But, although the latest period itself is not absolutely removed from the fortunate possibility, yet these mirabilia of recoveries are to be held of no account in the prognosis respecting any given case. The recovery is apt to be incomplete, the child remaining blind, paralysed, or imbecile: whether incomplete or not, a recurrence of the disease in the course of months or years is greatly to be dreaded.

Secondary Tubercular Meningitis in the Child.

As before explained, Meningitis is called Secondary when its symptoms have been preceded by manifestations not to be doubted of tuberculosis elsewhere. It has also been mentioned that, with this condition, the onset of the Meningitis is, as a rule, obscure; a fact which will not surprise the reader when he considers the nicety of the premonitory symptoms, and the slight prominence of the commoner invasion symptoms appearing in the midst of a state of tuberculosis already existing. A state of acute tuberculosis, we ought rather to say; for when the tubercular disease is of that chronicity which we sometimes see, lasting for years (insomuch that tuberculisation having probably ceased, the patient suffers from its permanent effects merely), the recurrence of actual tuberculisation is only somewhat less marked than its suprévention upon a healthy state. The small number of cases then (with regard to children, very small) which belong to the latter class may be dismissed from further consideration, differing as they do from primary Tubercular Meningitis only in this, that they run more rapidly to death. Per contra, in a case of acute tuberculosis the cerebral lesion may have reached the point of complete softening of the septum lucidum and fornix; and not have produced any symptoms of hydrocephalus which could be discovered even by the observer watching for them. Between these extremes with regard to curtailing of symptoms there are all possible grades.

Tubercular Meningitis, when secondary to cerebral tubercle, is attended by symptoms which are for the most part distinct enough. This, indeed, would almost follow from the law before laid down, for cerebral tubercle (that is to say, a tubercular tumour), which has caused symptoms whereby it has been recognised, must be so chronic that the onset of the Meningitis is well marked. If, on the other hand, the symptoms of tumour have been so slight as to have been insufficient for its diagnosis, then the case is, for clinical purposes, primary Tubercular Meningitis. Masses of yellow tubercle are often found imbedded in the brains of children dead of hydrocephalus.
acutus, whereof neither the prodromata nor the symptoms had led us to suspect the presence of anything more than the constant accom-
paniments of the latter disease. This only excepted, namely, the conclusion at which Rilliet arrived, "that meningitis, uncomplicated by tubercle of the cerebral substance, scarcely ever begins with convulsions:" although this is sometimes, and the converse frequently, not true; tubercles of the size of a hen's egg, at least, are sometimes found post mortem in those cases of Tubercular Meningitis which, neither at the invasion nor at any other time, have had convulsive movements.

It is uncommon for Meningitis to supervene upon chronic phthisis in children; when this does happen, the new disease has been, so far as I have seen, easy of discovery, the more easy the more chronic the precedent disease. Contrariwise, Meningitis which occurs in the course of acute tuberculosis of the pulmonary form, is mostly latent; when not so, very rapid in inducing death.

When tubercular peritonitis which has been diagnosed is com-
plicated by Meningitis, the latter is of the curtailed kind, apt to be overlooked, being, as it were, rather the harbinger than the cause of death—affecting another proof of the truth of that aphorism which may be here repeated under another form, that the more tuberculosis has involved the health at large, the more obscure are the signs of a sequential Meningitis: its premonitory and invasive symptoms have been anticipated. I have not known Meningitis to supervene upon tabes mesenterica of such gravity as to have been a disease by itself.

The recognition of the occurrence of Meningitis in the course of acute tuberculosis which has been previously known to exist, depends greatly upon the degree to which the brain becomes im-
plicated. Cerebral symptoms may be well marked (though shortened in duration, reduced to a week or less) even when they have been preceded by such grave symptoms, independent of the brain, as have not permitted us to doubt the existence of acute tuberculosis. Acute tuberculosis, not primarily cerebral, assumes for the most part one of two forms, namely, the typhoid form, or the pulmonary form.* I cannot do better than quote Rilliet's description of the typhoid form when it precedes Meningitis:—"In rare cases the invasion symptoms are more acute and febrile than usual, the skin is somewhat hotter, the pulse somewhat more frequent. The child complains of his head and belly at the same time; he does not vomit, but his bowels are obstinately constipated; he does not shriek, nor sigh, nor grind his teeth. The symptoms last from six to twelve days; fever continued; tongue covered with a thick fur; belly somewhat swelled and tender. The child is drowsy, but easily roused, answers sensibly; no pho-
phobia; pupils natural; pulse regular, equal, 120 or more; no spots or

* The reader who desires more information upon the subject of acute tuberculosis, may be referred to Rilliet et Barthez, Mal. des Enfants, iii, pp. 370, et seq. p. 481. Trousseau, Clinique Médicale, i. 536: Phthisie pulmonaire. Empis, La Granulie: Paris, 1865.
TUBERCULAR MENINGITIS.

sudamina anywhere; facies not that of hydrocephalus. This state is followed by the second (established) stage of meningitis." Let me add, that I have remarked, in such cases, the tongue to be pointed, with a central white fur and red tip and edges, and the bowels to be spontaneously relaxed. The *pulmonary* form is more common. The child sickens with what seems to be a bad cold; rapid loss of flesh and strength; fever rather high. The catarrh continues, fever increases, dyspnoea and lividity ensue; the rhonchi heard in the lungs become more and more abundant, fine, sharp, and metallic; the percussion note is high-pitched and hard, without losing in resonance. After two or three months from the beginning, symptoms of meningitis appear, more or less distinct, therein following the rule already several times laid down.

**Tubercular Meningitis in the Adult.**

It will be no small gain if, by treating separately of Tubercular Meningitis as it occurs in the adult, a single reader be put upon his guard against supposing that acute hydrocephalus is a disease peculiar to childhood. Our notions of acute tuberculosis in the adult have been too much limited by pulmonary phthisis; were every one to study acute tuberculosis in the child, and then to transfer the knowledge acquired to the investigation of the diseases of the full-grown, there would probably be no special difficulty in the recognition of Tubercular Meningitis at any age.

Meningitis, when intercurrent in the course of chronic phthisis, is characterised by more or fewer of the following symptoms:—Headache, complained of for the first time; or, if previously present, greatly increased in severity; mostly, but not always, very painful; frontal. Vomiting is an early symptom, occurring in almost every case: vomiting in uncomplicated pulmonary phthisis is uncommon, except when brought on by the violence of the cough. Convulsions, occasionally, mark the onset of the meningal disease. Delirium, of a quiet talkative kind, ensues. Sometimes the patients become speechless; they make ineffectual efforts to answer a question, or they look steadily at the speaker for a few moments, and then, without any expression of face, turn their head away. Numbness, paralysis, rigidity, of a limb or of some other part, may be a very early indication of the affection of the brain. At the same time, the symptoms, so far as the chest disease is concerned, "abruptly improve or actually disappear," *qua data porta ruunt.* Then follow: com-

* The smallness of my direct knowledge respecting the matters handled in the following section has compelled me to draw largely upon—

parative infrequency of the pulse, and irregularity both of pulse and respiration; squint; inequality of the pupils; the patient lies in a meditative, semi-unconscious state, then becomes more and more unconscious, while motorial symptoms, of any kind, ensue.

The phthisis is not often advanced. Primary Tubercular Meningitis is at least as common, in the adult, as secondary; and, like as in the child, the symptoms may be nearly wholly cerebral from the first, or may assume a typhoid character. In the latter case, the disease is rather acute tuberculosis than Tubercular Meningitis; the non-cerebral symptoms predominate, at least at first. In the other case, the symptoms do not differ from those previously described as occurring in the child, either in their character or their order of appearance; headache, at the beginning, is mostly very severe, but is not always so. Vomiting, strabismus, diplopia, more or less loss of power over some part of the body, convulsions, numbness, dilated pupils, infrequency of the pulse, early delirium, a cerebral streak,—the presence of any of these symptoms in an adult suffering from an acute illness, should suffice to put us on our guard: the physical examination of the chest does not often help the diagnosis. The duration of the disease is from eight to fifteen days.

DIAGNOSIS.—The diseases which are confounded with Tubercular Meningitis may be divided for practical purposes into two classes: the first comprehending those diseases which simulate the earlier, and the second those which simulate the later, periods of Meningitis. And it so happens that the resembling diseases of the first class are not attended, and of the second class are attended, by organic lesions of the nervous centres, or their appendages: this, speaking generally. The difficulty is greatest in the diagnosis of the earlier, the premonitory and invasive, periods of Tubercular Meningitis from the diseases of the first class; and the reason of the difficulty is obvious, namely, that the premonitory symptoms of Tubercular Meningitis are common to many diseases; so that the physician, full of a just dread of tuberculosis, and not wishing to be confronted by meningitis unawares, is continually suspecting tuberculosis when it is not present.

To have treated incipient hydrocephalus slightly is a mistake which, once made, is not readily forgotten: the patient's friends, at any rate, will remember the failure in prognostics. Loss of flesh going on steadily, is a symptom to which it is wise to give the worst possible meaning. Repeated vomiting, in the child or the adult, occurring as a new symptom during a state of good health, or after a period of poorliness, is worthy of all our attention. Very carefully do we examine a child who has had a convulsion, lest it should be the first warning of the existence of incurable disease.

TUBERCULAR MENINGITIS.

1. Simple exhaustion of the vital powers sometimes occurs so acutely and reaches such a pitch as to be mistaken for tuberculosis, or, indeed, actually existing Tubercular Meningitis. The exhaustion may be primary: a child, without any obvious cause, or perhaps in consequence of a change of diet, loses its appetite, and therewith its flesh; becomes pale, languid, and restless; there are no distinct dyspeptic symptoms; the nurse fancies that the child is feverish; the pupils are large, and do not act very readily; a convulsion, or a series of fits, may occur—no other symptoms of meningitis being present. Wary in our prognosis, we submit the child to the test of treatment. We order pounded meat, milk, wine, or brandy, the aromatic confection, or a mixture of muriatic acid, cinchona, and chloric aether: the next day we shall be able to prognosticate much less dubiously; possibly, in the end, we may really have warded off Tubercular Meningitis. The exhaustion which is secondary to acute diseases, and especially to the longest acute disease, typhoid fever, is sometimes so great as to be mistaken for established hydrocephalus. It is chiefly in the houses of the poor that we see children, wofully manhandled during their illness, wasted past belief. The alimentary canal ceases to perform a single natural function; the disgust for food is complete, the children are not even thirsty; forced to swallow broth, or food which is called light by a foolish metaphor, vomiting ensues; the child is somnolent, yet extremely restless, lies rooting with his head in the pillow, tossing from side to side, waving his arms in the air, or constantly passing his hand over one side of his head; incessantly whining, occasionally screaming, and, if old enough, complaining, when asked, of severe pain in the head; the tongue rolls from side to side, the lips are dry and peeling; the eyesight becomes dim, the somnolence deepens into unconsciousness, and the child dies. Post mortem we find the marasmus has invaded the brain; it is small and very bloodless; the pia mater is watery. The sketch is from nature, and the possibility of mistake is more than a mere possibility. The diagnosis will depend upon the previous history of the case, upon the character of the symptoms, and the order in which they have been developed.

2. Derangement of the Alimentary Canal.—i. Acute dyspepsia causes symptoms which are almost identical with those of the earlier periods of Tubercular Meningitis. To take an example: a child of four years old, of a phthisical family, suddenly vomits several times, becomes feverish, complains of pain in his head, has no appetite, coughs a little; is very irritable, thick-looking, and heavy; greatly dislikes being touched; the bowels are confined. Occasional vomiting continues; in the course of a few days (measured by the thermometer, the pyrexia in such a case may last a week) the fever diminishes, the pulse becomes irregular and much less frequent. But, happily, at the same time the child begins to look brighter, and to sleep better. It is important to bear in mind that, during convalescence, even from so trivial a complaint as dyspepsia, the pulse of many children becomes actually infrequent and very irregular. To increase the
difficulty, I have known one pupil to become larger than the other at the same time, and to remain so several days. A diagnosis off-hand is often impossible; there is no help for it but expectation—expectation of the active kind. The patient is visited more often, examined more minutely, and treated more carefully than if there were no doubt; at least he does not suffer, probably he derives benefit, from the uncertainty of the physician. II. *Gastro-intestinal Catarrh.*—A little child, who had lost appetite and flesh for several weeks past, has one day a fit, which lasts, say, a quarter of an hour; on the same day her bowels become loose; they remain so for a week, then she vomits several times. All this time there is more or less pyrexia; what heaviness there is, caused by the diarrhoea, tends to complicate the diagnosis. From one example the reader will learn all: diarrhoea, although no doubt an uncommon, is not an impossible, accompaniment of Tubercular Meningitis. When dentition coincides, the pain caused thereby is not always distinguishable from the headache of Meningitis: nor must we attribute too much to dentition; I have known the canines to pierce the gum and Tubercular Meningitis to break out at the same time.

3. Typhoid fever resembles not so much Tubercular Meningitis as acute tuberculosis. But typhoid acute tuberculosis is sometimes immediately fatal by way of meningitis. With regard to children, the physician, when in doubt, is far more ready to suspect acute tuberculosis than typhoid fever. The difficulty is caused by the aberrant forms of typhoid fever which we meet with; cases with confined bowels, with an empty belly, with spots which are small, dusky, and hard to the feel, or even vesicular at the apex; cases which have the facies of acute tubercle; cases complicated with consolidation of one or other apex of the lung, and attended by universal mucous rhonchi. In the adult, however, typhoid fever is far more likely to be suspected than acute tuberculosis. The practitioner, if fully aware that acute tuberculosis does occur in the adult, will not fail of making the diagnosis as soon as it becomes possible.* Diarrhoea may accompany acute tuberculosis.

4. Small-pox and scarlet fever, both of which invade by vomiting, may be attended at the same time by very severe cerebral symptoms.†

5. Tubercular Meningitis sometimes at first simulates the symptoms of ulcer of the stomach,‡ or may assume a quasi-hysterical form. §

6. Simple convulsions cannot per se be discriminated from those which are precursory of Tubercular Meningitis.

7. The vomiting of incipient pleurisy and pneumonia, if accom-

* See the twenty-eighth case in Louis (op. cit.), wherein acute tuberculosis very closely simulated typhoid fever. Also several cases in Empis.
† See vol. i. pp. 336 and 436; also Rilliet and Barthez, iii. 224.
‡ Empis, p. 159.
§ A remark which I owe to Dr. Jenner. I have recently seen an illustration of its great practical value.
COMPANIED by convulsions, as may be the case, is apt to divert attention from the chest to the head. But acute tuberculosis tends to cause inflammation of all the serous membranes; and, as a matter of actual experience, I have heard the friction sound of pleurisy in cases of Tubercular Meningitis; so that, on the contrary, attention must not be diverted from the head to the chest. The rhonchus of lobular pneumonia is less general than that which we hear in some cases of miliary tubercle of the lung. In the lobular pneumonia of children, chlorides are often present in the urine while the body-temperature is still high.

1. By simple meningitis is meant Meningitis which occurs totally unconnected with the tubercular diathesis. Rilliet thus epitomizes the chief points, wherein simple differs from Tubercular Meningitis (Mal. des Enfants, i. 122):—"The children present no sign of tubercle (i.e. during life) anywhere. The disease occurs in the midst of good health, or if it be secondary, it has been preceded by an acute, non-tubercular disease, or an accident. The invasion symptoms are these: violent convulsions accompanied by intense febrile movement, great acceleration of the respiration; or severe frontal headache, with fever, bilious vomiting, and (on the first, second, or at latest the third day) excessive restlessness, preceded by somnolence; furious delirium; great collapse; constipation slight. Course rapid; continuous increase of the gravity of the symptoms; tendency to exhaustion. Duration from twenty-four hours to six days; rarely longer." These observations are based upon thirty-two cases.

Simple meningitis (not traumatic) of the convexity is extremely uncommon in London. Sporadic cerebro-spinal meningitis (the membranes of the base and ventricles of the brain, and the sub-arachnoid space of the spinal cord, being especially affected), totally unconnected with tubercle, has been, in my experience, comparatively common. Rilliet's description of simple meningitis labours under this defect, that, because he did not in many cases open the spinal canal, he has confounded the two diseases mentioned above, they being, in all probability, totally distinct in nature. Cerebro-spinal meningitis is frequently quite a chronic disease; when acute, it resembles Tubercular Meningitis very closely.*

2. Cerebral abscess occurs under several different circumstances

* The symptoms are the same as those of epidemic cerebro-spinal meningitis, to the article upon which subject refer, or to the very numerous descriptions of the several epidemics in France, Germany, and Ireland, enumerated by Hasse in Virchow's Hand- buch, Bd. iv. Abth. i. A good account of an epidemic in West Prussia, in 1865, has been published by Dr. Rummel in a volume on children's diseases: Neu-Ruppin. 1865.
and differs accordingly in clinical details. The diagnosis of Tubercular Meningitis continually opens up the whole field of diseases of the brain; the ability to distinguish them greatly depends upon a full and minute knowledge of their history. The reader will refer to the special articles, and make the necessary comparisons for himself. i. Cerebral abscess of pyemic origin may be dismissed at once as never complicating diagnosis. ii. Cerebral abscess due to suppuration of the pia mater, going on so far that numerous large collections of pus are protruded into the brain substance which disappears by rapid atrophy, so far as I have seen, does not modify the ordinary course of simple meningitis. iii. Cerebral abscess due to disease of bones of the skull differs in its symptoms according as pyæmia is combined with it or not. Abscesses merely pushed into the brain, inasmuch as they are not commonly combined with disease of the sinuses, cause symptoms which are altogether those of an intracranial tumour. Abscesses which are separated from the diseased bone by a layer of brain tissue (often greatly altered), and which are therefore presumed to have originated in the very midst of the lobe affected, are, for the most part, attended by pyæmia, the symptoms being complicated accordingly. But pyæmia does not always accompany even these non-peripheral abscesses, and then the difficulty of diagnosis from Tubercular Meningitis is very great, especially if we bear these facts in mind: first, that it is not uncommon for otorrhœa to concur with Tubercular Meningitis; and next, that external otorrhœa, in cases of cerebral abscess due to disease of the pars petrosa, may not set in until a week before death, and may have been preceded by the gravest symptoms of that intracranial otorrhœa which destroys the patient. The pulse of cerebral abscess is more persistently infrequent than that of Tubercular Meningitis.

3. Thrombosis of the sinuses of the dura mater, when secondary to neighbouring inflammation, does not admit of diagnosis, unless there be present pyæmal symptoms and some obvious possible cause of disease of the sinuses; caries of the pars petrosa is by far the most common. Thrombosis secondary to debilitating causes may be suspected if signs of disease of the brain follow a profuse diarrhœa or hæmorrhage in a young child, but could hardly be distinguished from the simple exhaustion before described; while, on the other hand, I have known a decolorised softening thrombus to occupy the whole bore of the upper longitudinal sinus, to be attended by large sub-arachnoid hæmorrhages, and to have caused no symptoms during life.

4. Caries of the atlo-axoid joint may cause such brain symptoms as to lead to a suspicion of the possible existence of Tubercular Meningitis. It is well, therefore, in a doubtful case, to examine the cervical region carefully, so as to discover any thickening and swelling of the soft parts.

5. Arachnoid hæmorrhage, according to Legendre, may simulate

* These remarks apply also to cerebral abscesses not due to diseased bone.
Tubercular Meningitis.* This can be only in exceptional cases of the former rare disease.

6. Non-tubercular acute hydrocephalus, due to a primarily morbid state of the lining membrane of the ventricles, and unaccompanied by meningitis, is supposed to occur, and to be a cause of death, preceded by symptoms indistinguishable from those of Tubercular Meningitis. The cases which are brought forward to prove the existence of the disease in question are, to say the least, so wanting in details as to leave full room for doubt, especially when we bear in mind that Tubercular Meningitis may occur, and no tubercle be positively discoverable in the brain or its membranes.

7. An intracranial tumour of the fibro-plastic, myeloid, soft sarcomatous kind, which approaches nearest to cancer in general appearance and in rapidity of growth, may cause symptoms which resemble those of Tubercular Meningitis so closely, that, for a week or two from the beginning of the disease, it may be impossible to arrive at a diagnosis. In the case of the tumour, the pyrexia ceases for several weeks before death, and the disease becomes of a more chronic character.†

8. Local hypertrophy of the brain is sometimes attended by symptoms which, at first sight, are like those of Tubercular Meningitis. We discover afterwards that the hypertrophy is, comparatively, very chronic.

9. Every practitioner, from time to time, will come across an acute febrile disease, accompanied by symptoms which seem to point unmistakably to some affection of the brain; there being every reason to exclude the notion of suppressed exanthemata or analogous disorders. After one or several weeks of coma, delirium, severe headache, or whatever may have been the prominent symptom, the patient recovers, and we are left quite unable to say what has been the matter with him. To go more into detail, I could not do otherwise than narrate a series of cases which would differ from each other in most important points, and have nothing in common excepting pyrexia and brain symptoms. There is, generally, something wanting which makes us suspect that we have not to do with Tubercular Meningitis. Brain fever is as good a name as any whereby to designate these different anomalies; cerebral congestion, which is more commonly used, involves an explanation which is probably often wrong, and certainly never proved to be right.

Morbid Anatomy.—I shall describe the morbid appearances of Tubercular Meningitis, in that order wherein they are brought under view during a post-mortem examination.

Separation of the calvaria is easily effected as a rule. Occasionally the dura mater seems to be hyperæmic. Slitting up the longitudinal

* Rilliet and Barthez, ii. 259.
† The subject of this outline sketch was a boy under the care of Dr. Hillier at the Children's Hospital.
sinus, a pale narrow clot is seen in the posterior half: sometimes the sinus is filled with fluid blood and loose coagula, sometimes with a large black shining thrombus. Removing the dura mater, the great arachnoid sac is found to be destitute of fluid; the membrane itself is dry, and, what is more, sticky to the finger passed over it. Scrape the surface gently with a scalpel and the sticky matter will be removed, minute in quantity, and puriform in appearance. Reddish serosity has been observed in the arachnoid sac by Senn and Becquerel; transparent or turbid serosity by Rilhiet and Barthez. This serosity, was it observed before or after the brain had been removed? If after, the observations are quite valueless, unless indeed certain precautions were taken which probably were not. The ordinary unnatural state of the arachnoid may be looked upon as the sign of a feeble inflammation; similar stickiness is common in incipient pleurisy and peritonitis. Empis once found the arachnoid sac obliterated by old adhesions in a patient who had probably passed through an attack of acute tuberculosis long before. Still more to the point: in Tubercular Meningitis there is almost constantly present, adhesion, more or less firm, of the opposed surfaces of the great longitudinal fissure, especially just above the corpus callosum.

The pia mater affords more unequivocal signs of disease. First, as to vascularity. Sometimes there is obvious hyperemia of the whole convexity of the brain: it looks rosy; examined minutely, the fine vessels are seen to be injected everywhere; the body having lain on the back, the injection is nearly as well marked over the anterior as over the posterior lobes. More commonly, the capillaries are not much injected; what colour the surface has being derived from large veins full of blood. Sometimes capillaries and veins both are emptied of blood, so that the brain has a most striking appearance, exactly resembling in colour painters’ putty. These differences depend for the most part upon the amount of pressure from within to which the surface of the brain has been subjected. Secondly, as to edema. Excess of clear serosity is commonly met with in the meshes of the pia mater between the convolutions; sometimes the effusion is semi-opaque and lymph-like. Thirdly, as to the tubercles. Examine the membranes of the lateral regions of the brain, corresponding in position to the temporal fossae, and almost certainly miliary tubercles will be seen: not that they are absent elsewhere, but they are most common at the spots indicated; they are common at the bottom of the great longitudinal fissure also. These tubercles are beneath the arachnoid, often adherent to its under surface; those exposed to pressure against the skull are more or less flattened. Alongside the branches of the middle cerebral artery it is common to find a firm, greyish, semi-transparent material, which is probably infiltrated tubercle. Minute opacities of the pia mater are sometimes seen in the same region, most numerous by far in the neighbourhood of the miliary tubercles, and possibly tubercular in nature, a sort of white “tubercular dust.” Sometimes the tubercles are yellow at their
TUBERCULAR MENINGITIS.

centre, sometimes all of them are yellow throughout, remaining crude. The number of tubercles present may be very large. There may be none at all. Raising the membranes from the surface of the brain, small portions of the brain substance adhere to the membranes so as to be removed with them: not that this is always the case; the difference depends upon the degree which the softening of the cortex has reached. The amount of vascularity of the pia mater and the degree of cortical softening are not always in direct proportion. The convolutions of the brain are more or less flattened, the intervening sulci narrowed. Proceeding to slice the brain, we perceive that the colour of the cortex is increased in depth if the pia mater be hyperæmic, or diminished vice versâ, or remains natural. As a rule, the centra ovalia are anaemic, sometimes exceedingly so. Sometimes the texture of the whole brain is obviously softened. When we reach the lateral ventricles, they are found to be distended with fluid; a colourless serosity, of low specific gravity, mostly clear, but becoming faintly turbid when agitated, slightly albuminous, containing chlorides and phosphates. The quantity of the fluid is from one to four ounces; sometimes more. In one case I found a drachm of fluid in the fifth ventricle, the septum lucidum being everywhere perfect. The foramen of Monro is dilated. The lining membrane (ependyma) of the ventricles is toughened, sometimes obviously opacified in places, especially in the sulcus between the corpus striatum and thalamus opticus. Viewing the surface of the lining membrane sideways, we see that it looks as if it had been sprinkled with the finest dust. It seems probable that this condition is mostly due to small heaps of cells, a commencing suppuration of the lining membrane;* sometimes the dusty look, in part at least, is due to a minutely wrinkled state of the ependyma, resulting from the stretching it has previously undergone. Occasionally we see larger granulations than those described, greyish elevations, something midway, in every respect, between the sandy specks and miliary tubercles. The whole ependyma down to the fourth ventricle may be thus granular, or this sanded appearance may be quite absent. The vessels of the ventricles, the choroid plexuses and veins of Galen, with their tributaries, are sometimes obviously full of blood, but more often not so, and sometimes almost empty, the plexuses being quite pale. Softening of the cerebral matter beneath the ependyma is almost always found; the septum lucidum and under surface of the fornix are reduced to a pulp; the corpus callosum, walls of the posterior cornua, and other parts are often similarly affected. The question naturally arises, What are the causes of these grave lesions of the ventricles—the dropsy and the softening? We cannot suppose that the brain substance will soften by passive imbibition of fluid; were it possible, there would be no reason why softening should not occur in health. But the fluid is forced by its excess into the brain substance? This is not so, because the ventricles are sometimes nearly empty when their walls are thoroughly softened.

Mechanical congestion might conceivably be the common cause of the dropsy and the softening; but, in the great mass of cases, it is impossible to discover any impediment to the return of blood from the ventricles. The blood may be made to flow from the veins of Galen back into the straight sinus with perfect ease; moreover, as stated above, the plexuses are often quite pale, and the veins nearly empty. It would be difficult to explain the effusion of serosity into the pia mater, and the cortical softening, by mechanical congestion. Inflammation will account for all the conditions. We have already seen that the ependyma presents an appearance common in inflammation of surfaces,—namely, proliferation of cells. The connective tissue which underlies the epithelial layer of the lining membrane, is gradually lost in the neuroglia or interstitial non-nervous tissue of the brain.* And hence, inflammation of the ependyma leads to effusion of serosity both into the ventricles and into the brain matter; the softening being rendered complete by the mal-nutrition which ensues in consequence of the more or less arrested capillary circulation. The great anatomical sign of inflammation, redness, is often wanting, no doubt; but the inflammation is, as it were, glaucomatous. The statement of Dance, approved by Empis, that the amount of effusion into the ventricles and of brain softening are in inverse proportion, is not strictly true. In what manner did these observers determine the amount of the effusion, when there was the dilated foramen of Monro ready to let the fluid out as fast as formed? Moreover, we often find the ventricles distended by fluid, and the septum between them broken down. To proceed. The velum interpositum is natural, or oedematous, or thickened and somewhat opacified; studded, it may be, here and there with mililiary tubercles. The condition of the third ventricle resembles that of the lateral ventricles: the distension is ordinarily less because of the resistance of the thalami optici; in front of these masses the dilatation sometimes goes so far as to expose the pia mater of the base: the commissura mollis is often more or less torn and speckled with capillary haemorrhages. The fourth ventricle also is distended. I have several times examined the cerebro-spinal opening† in situ, and have always found the membranes about it perfectly healthy. When the spinal canal is laid open before the calvaria has been removed, to puncture the sub-arachnoid space (internal arachnoid of Hilton) causes the escape of a certain quantity only of fluid, merely the excess in the spinal canal; when the calvaria has been removed before the spinal sub-arachnoid has been touched, the cerebral ventricles can be drained completely by opening the membranes of the cord. The spinal internal arachnoid is distended with fluid, especially around the cauda equina. I have never observed any other morbid condition within the spinal canal, but then it

† It was the perusal of Mr. Hilton's book on Rest and Pain (London, 1863) that led to the examination of the cerebro-spinal opening and sub-arachnoid space in Tubercular Meningitis, and, so far as I know, for the first time.
has been examined in a minority of cases. Removing the brain from the base of the skull, we occasionally find adhesions of the two surfaces of the great arachnoid about the circle of Willis. The membranes at the base of the brain are sometimes greatly injected, sometimes much less so. Miliary tubercles sometimes swarm in the sylvian fissures, interpeduncular space, round the crura cerebri, and on the top of the cerebellum: ordinarily they are not in very large numbers; occasionally there is only a tubercle here and there; still more rarely no unquestionable tubercles can be found. Sometimes the tubercle is of the crude yellow variety. Other parts of the membranes of the base than those mentioned sometimes present tubercles. Besides being tuberculised, the membranes (i.e. pia mater, sub-arachnoid) undergo those changes which have caused the name of meningitis to be given to this disease. The meshes of the pia mater are filled with serosity (clear or turbid), or with lymph-like material, or with puriform: sometimes the membrane seems to be merely thickened, toughened, and opacified. The inflammation of the pia mater is most marked in the interpeduncular space, but tends to spread forwards along the optic and olfactory nerves, sideways into the sylvian fissures, and backwards round the crura cerebri on the upper surface of the cerebellum, or right over the pons and as far back, it may be, as the medulla oblongata. There is no proportion between the amount of tuberculosis and of meningitis. Softening of the brain cortex is usual; the under surface of the anterior lobes, and the under surface of the cerebellum, are affected with especial frequency. Softening of the optic commissure and of the smaller nerves is mostly found. The sinuses at the base present nothing abnormal.

Accidental Lesions.—1. Masses of yellow tubercle are often met with in examining the brains of children dead of Tubercular Meningitis. Sometimes the tubercle is softened. 2. Capillary haemorrhage coincides with the softening of the cerebral matter, when the softening has reached a certain point. Most frequently seen in the soft commissure, haemorrhage sometimes occurs in other parts, the brain proper, the pons varolii, &c. leading to utter disorganization of the tissue. 3. I have seen miliary tuberculosis of the brain substance carried almost as far as can be conceived possible—a whole hemisphere of the cerebrum so much softened that it was easy to wash all the brain matter away; which done, there remained a close network of injected and dilated capillaries studded everywhere with miliary tubercles. The meningitis in this case ran a very rapid course. 4. Meningeal apoplexy, and a decolorised thrombus of the superior longitudinal sinus, I observed in one case of tuberculosis of the meninges, unattended with obvious inflammation of them.

Other Organs.—Tuberculosis of the lungs, liver, spleen, lymphatic glands, and kidneys, concurs with the brain disease. The tubercle is mostly miliary, sometimes yellow crude or softened. A girl of four*

* Under the care of Dr. West in the Children's Hospital.
died on the tenth day of tubercular meningitis without prodromata; post mortem we found numerous miliary tubercles in the pia mater, great ventricular effusion, very little lymph at the base of the brain, and absolutely no tubercle in any other part of the body (which was carefully examined) excepting a small mass of cheesy material in each lung. Tubercular ulcers of the intestines are often present: also intussusceptions easily reduced. The children will have frequently preserved a large amount of subcutaneous fat.

Prognosis and Treatment.—Tubercular Meningitis has been known to end in recovery. It is necessary to state this as a matter of science, but in practice it unhappily comes to this, that a person suffering from Tubercular Meningitis will inevitably die. Rillict relates that Franck, when told of Heim and Gélis, who cured a large proportion of their cases of this disease, and of Formey, who cured nearly all those to whom he was called in time, replied: "Etsi viri graves de hoc sibi suaviter blandití sint, absque ulla in istos injuria, quæ nobis ipsis non contigerint dubitabí licebit." The prognosis is only too easy; reckon twenty-one days from the invasion symptoms, and, in the majority of cases, that will cover the fatal termination. It is very unwise to venture upon a more precise prognosis.

What, then, is to be done by way of prevention of the disease? The prophylactics and ordinary hygienics are the same—animal food, change of air, warmth to the surface, moderate exercise; to which may be added cod-liver oil and cinchona. The sad prognosis of Tubercular Meningitis does not attach itself to acute tuberculosis. No doubt many persons recover from acute tuberculosis: knowing this, any patient suffering from what is possibly acute tubercle should be treated very carefully, so as, if possible, to stop the disease and prevent involution of the brain. Nor should the physician give way to the fatalism which follows upon being sure of the existence of hydrocephalus, until he is quite certain of his diagnosis. As much liquid food as possible should be given to the patient, by means of a syringe placed between the teeth, if need be. There is no doubt that leeches, active purging, blistering, ulcerating, and such-like measures, hasten the advance of death. It is best not to shave the head unless there be a distinct indication. If the corneæ begin to ulcerate, it is as well to keep the eyelids closed by means of a little sticking plaster.*

* The majority of the cases of Tubercular Meningitis which I have seen have been under the care of Drs. West and Hillier at the Hospital for Sick Children, London; and here I wish to offer my acknowledgments to those gentlemen for favours and opportunities, without which the preceding paper could not have been written.
CHRONIC HYDROCEPHALUS.

BY J. SPENCE RAMSKILL, M.D.

This disease is a real dropsy occurring within the cranial cavity. The fluid may be collected in the sac of the arachnoid or in the ventricles of the brain, beneath the arachnoid membrane. The affection may be congenital or acquired. When congenital, it is generally, but not invariably, due to an arrest of development of the cerebral mass, although even in such cases the dropsy has been regarded by Rokitansky and Vrolik, whose opinion is quoted and endorsed by Dr. West,* as not a mere passive dropsy, but as the result of a slow kind of inflammation of the arachnoid, especially of that lining the ventricles, which may have existed during life. Such inflammation may also attack the child after its birth, and "each year," says Dr. West, "leads me to estimate more highly the share of inflammation of the lining of the ventricles in the production of Chronic Hydrocephalus. Acquired Hydrocephalus begins to show itself about the period of the first dentition." According to Dr. West (p. 124), out of 54 cases, 18 of which came under his own observation, some indications of the disease were observed in 50 before the child was six months old; in 14 the symptoms existed from birth, and in 21 more they appeared before the completion of the third month. In some rare cases, the disease attacks children, seven, eight, or nine years old, who until then had seemed to be free from all cerebral complaint. In some extremely rare cases, this affection has been known to attack persons of advanced life. Dr. Watson† cites several instances of the kind, one of which occurred under his own observation. A young and distinguished lawyer of his acquaintance had one or two attacks of rather sudden loss of consciousness, while engaged in the Court of Chancery: by degrees he became dull, stupid, forgetful, and at length insensible. In this condition he died. A large quantity of serous fluid was found distending the ventricles of the brain. No other alteration could be detected. A case of Dr. Baillie's is quoted by the

* Diseases of Children, p. 121.  † Practice of Physic, 4th edit. p. 464.
same author, the patient being a man fifty years old. The celebrated Dean Swift died of this complaint at the age of seventy-eight, three years after the commencement of the disease.*

Golisi also mentions three instances in which this affection began in advanced life: two of the patients were about seventy years of age; the third, who was a physician at Vienna, likewise died in the decline of life, having suffered under the disorder for ten years. When Hydrocephalus shows itself some time after the birth, it is generally accounted for by the presence of a tumour (cancer, tubercles, or cysts). The dropsy in such cases is produced, as was pointed out by Dr. Whytt long ago, by the same mechanism as ascites in cases of scirrhus of the liver, of the spleen, or of the pancreas. Any deposit compressing the veins of Galen, which bring back the blood from the ventricles of the brain, is sure to lead to accumulation of serosity within those ventricles.

Dropsical effusion within the sac of the arachnoid is sometimes the result of a former haemorrhage into that cavity, as pointed out by Legendre, and supported by Rilliet and Barthez. In some very rare cases, chronic hydrocephalus seems to be a result of the acute disease. Two cases of this kind are recorded by Rilliet, one in his work on "Diseases of Children," p. 162, and the other in the "Archives Générales de Médecine," Dec. 1847. Dr. West also relates a case in which the first link in the chain of morbid processes seems to have been an injury to the head; the child, when five months old, having fallen out of the arms of the person who was nursing her, and on the same day she had a fit, and remained stupid and senseless for hours.

Anatomical characters.—1. Ventricular Hydrocephalus.—The quantity of fluid varies from a few ounces to a few pounds. In a case mentioned by Trousseau,† the head measured a mètre (39·3 inches) in circumference, and about thirty pounds of fluid were found in the ventricles. The same author cites another case from Franck, in which the fluid amounted to fifty pounds.

As a necessary consequence of the accumulation of fluid, the ventricular cavities are considerably enlarged, the openings through which they communicate with one another are considerably dilated, although in some instances, from the pouring out of lymph, these apertures may get closed, and the fluid may therefore accumulate in one part more than another, producing an unsymmetrical enlargement of the head. Thus, Vrolik‡ has related the case of a young man who died from chronic hydrocephalus at the age of twenty, and in whom a false membrane had occluded the foramen of Munro through which the two lateral ventricles communicate.

The walls of the dilated ventricles may be of normal consistence, or even of greater consistence than normal. Rilliet and Barthez state that they have been able, in some cases, to dissect the condensed

---

* Practice of Physic, 4th edit. p. 464.
† Trousseau, Clinique Médicale, 2e edit. p. 247.
‡ Traité sur l'Hydrocéphalie interne. Amsterdam, 1839.
mass into several layers. In other cases the walls feel softer, and oedematous for some little distance. The brain mass above the ventricles becomes thinned and unfolds itself. The convolutions are flattened out, and the sulci between them disappear. The cerebral substance looks pale and anaemic. In some cases it happens that the commissures of the brain yield, and that the whole, or a portion of the fluid which it contains, escapes into the cavity of the cranium. This appears to have taken place in the well-known case of Cardinal, whose skull contained seven or eight pints of fluid, "while the brain lay at its base with its hemispheres opened outwards like the leaves of a book."* When the accumulation of fluid has resulted from inflammation of the membrane lining the interior of the ventricles, that membrane is found thickened and rough, and in some cases in a granular condition.

2. Intra-arachnoid Hydrocephalus.—When the result of haemorrhage into the arachnoid sac, the fluid is found more or less yellowish in colour, and may be even more or less mixed up with thin, serous blood. When it has been poured out to fill up the vacuum in the skull due to defective development of the brain, it is perfectly limpid and clear. The sinuses of the dura mater in this, as in the preceding form of hydrocephalus, are either empty, or are found to contain blood, both liquid and coagulated. The fluid of hydrocephalus, when tested by heat and nitric acid, is found to contain albumen, chloride of sodium, soda, and traces of salts of lime and potash have also been found in it. Urea was detected by Dr. Bostock in his examination of the fluid found in Cardinal's head.

Condition of the Bones in Chronic Hydrocephalus.—They are generally found to be considerably thinned, and transparent; if the union of the sutures has been completed, the bones are found to be less firmly united than usual, with less dovetailing; and there are numerous osa triquetra found in the lines of the sutures. In some cases, the bones have been found of normal thickness, and in rarer ones they have been of greater thickness than normal (Rilliet and Barthez), hard, compact, and resisting.

Symptoms.—When the disease is congenital, signs of cerebral disturbance manifest themselves very soon after birth. There may be either strabismus and rolling of the eyes alone, soon followed by gradual enlargement of the head, or convulsions recurring pretty frequently may set in.

According to Dr. West,† "enlargement of the head is by no means invariably the first indication of Chronic Hydrocephalus. In twelve out of forty-five cases, fits, returning frequently, had existed for some weeks before the head was observed to increase in size: in six, the enlargement of the head succeeded to an attack resembling acute hydrocephalus; and in four other instances it had been preceded by

* Bright's Reports, vol. i. part i. p. 483.
† Diseases of Children, p. 121. 5th edit.
some well marked indication of cerebral disturbance. In the remaining twenty-three cases no distinct cerebral symptoms preceded the enlargement of the head." Failure of nutrition is almost invariably present, although Rilliet and Barthez assert that "the nutritive functions are as a rule well performed in hydrocephalic children, unless they be in an advanced stage of tubercular cachexia, or chronic intestinal catarrh. Except such cases, the children are plump and well nourished, and even have sometimes an abundance of fat which is certainly morbid."* The cases, however, in which nutrition is unaffected, form the exception, not the rule. The child sucks well, voraciously even, and yet does not grow; he may even waste. His bowels are generally constipated, and his motions are unhealthy. The gradually increasing head soon attracts notice, and the peculiar physiognomy and aspect of a hydrocephalic child soon develop themselves. The fontanelles enlarge, and the anterior one is seen often to pulsate, and grow tense and prominent, and at such times there is heat of the head, and the child is more restless than usual. The sutures of the head widen, and the head by degrees assumes a globular shape. The forehead is round and prominent, the orbital plates of the frontal bone gradually become slanting, and the eyeballs become half hidden under the lower eyelid, so that the cornea cannot be seen until this is depressed. The parietal bones being pushed outwards and their edges being last to ossify, there is a considerable increase of the sagittal suture, whilst the occiput is driven downwards and backwards, in some cases to such a degree as to be almost horizontal. On applying the hand over the opened sutures and fontanelles, a distinct sensation of fluctuation is perceptible. The hair grows very scantily on the head, on which very large distended veins are seen to ramify. The face is small, and contrasts remarkably with the large size of the head; and looks triangular, with the apex of the triangle at the chin. The child's expression is dull and stupid, and he has a very aged look: he cannot sit up, or hold up his head, but lies down constantly. As the fluid continues to accumulate, and the disease progresses, the sight becomes impaired, and is completely lost after a time; the eyes are bright and shining, but restless and oscillating. Hearing is as a rule preserved much longer, but is lost at the close of the disease. Paralysis often sets in; contractions and rigidity of the limbs and trunk are not very rare, according to Rilliet and Barthez, particularly in very young children (p. 160). Occasional attacks of laryngismus stridulus are not unfrequent, and they may even come on before there is much enlargement of the head. (West.) That form of Chronic Hydrocephalus which results from the transformation of a cyst, the result of haemorrhage into the arachnoid sac, may be recognised, according to Legendre, "by its being never congenital, by generally beginning about the tenth month; that is to say, about the time when the teeth begin to appear. The head, indeed, enlarges gradually, but does not acquire so large a size as in internal hydrocephalus; while, lastly, it is always preceded

by convulsions, or by some other form of active cerebral disturbance, which marks the date of the occurrence of hemorrhage."* At best, however, the diagnosis can be but hypothetical. When hydrocephalus becomes developed after the sutures are united the bones, being subjected to pressure, become thin, and in some cases the sutures have been known to give way. Such cases are spoken of by Rilliet and Barthez, who also quote from the "London Medical Journal," (pro 1790, p. 56), the case of a child who at the age of nine years, and eleven months before its death became affected with chronic cerebral symptoms. Nine months and a half after the first manifestation of the disease, the sutures of the cranial bones, chiefly the coronal, began to open. At the time of his death the distance between the edges of the coronal suture measured half an inch, and at the spot where the lambdoidal joins the sagittal suture, there was a marked opening, so that the occipital bone was completely free.† As a rule, however, when hydrocephalus begins after the sutures are united, the head does not enlarge considerably, although it may do so in some rare instances, as in a case mentioned by Rilliet and Barthez (p. 165), of a child nine years old, who from the age of eight exhibited the symptoms of hydrocephalus, and whose head became enormously enlarged in spite of the ossification of the fontanelles. The size of the head in chronic hydrocephalus varies considerably; it has been known to measure two, and even three feet in circumference. In the Museum of the Faculty of Medicine of Paris, there is a hydrocephalic skull which measures 39 inches round. The shape of the head is generally globular and flat at the top, but in some rare cases it is conical, shaped like a sugar-loaf.

The termination of the complaint is generally in death, which occurs either from some intercurrent affection, hydrocephalic children being always weakly and unable to resist disease, or from an attack of laryngismus stridulus, or from convulsions due to passing congestion of the meninges, or lastly from gradual exhaustion, from positive asthenia. The disease extends at least one or two years, but it may last from four to ten years. Cases have even been recorded of individuals living to an advanced age who had been hydrocephalic from infancy. Thus Dr. Bright's patient, Thomas Cardinal, lived to nearly thirty. Franck, cited by Trouseau,‡ speaks of two individuals, the one aged seventy-two, and the other seventy-eight, who had been hydrocephalic from infancy. Strictly speaking there is no cure of the complaint, but merely an arrest of its progress. Fluid may be no longer poured out, but that which has been already effused is not absorbed. The sutures and fontanelles ossify and close, and a good manyossa-wormiana are then found along the lines of union: these

† Dr. Watson (p. 464, 4th edit.) also cites two similar cases, one from Dr. Baillie, the patient was a boy, seven years old; and the other from Dr. Yeats' work on Hydrocephalus—a boy nine years old.
‡ Clinique Medicale, p. 247.
are like nuclei for the formation of bony matter. In some instances it has been said that a real cure takes place; that there is increased activity of the nutrition of the brain producing hypertrophy of that organ, the fluid being absorbed and new matter deposited in its stead (Otto).* Such cases, however, must be quite exceptional, and the rule is that the fluid is unabsorbed and remains in the cranial cavities. The patient's intellect and senses are not perfect it is true, but are still sufficient to enable him to perform the ordinary duties of life, although he is apt to be fretful and irritable, and somewhat childish in his ways.

Diagnosis.—1st. Congenital hydrocephalus has to be diagnosed from encephalocele and perforating fungus of the dura-mater. In encephalocele, the feel of the swelling is doughy and elastic, not fluctuating; it is local and not general, and it is not transparent. In cases of fungus of dura-mater which has perforated the cranium at birth, the general size of the head is not affected, the perforated spot can be easily detected, and it is over the central parts, not near the sutures or fontanelles; the mass feels doughy-elastic, quasi-erectile, and when it is compressed, symptoms of irritation are produced. Acquired hydrocephalus has also to be distinguished from a merely excessive development of the head apart from any disease. The absence of all cerebral symptoms is sufficient in such cases to establish the diagnosis. Sometimes hydrocephalus may be suspected where none exists, because of the disproportion between a small, emaciated, triangular face and largely developed skull. Rilliet and Barthez candidly confess to an error of this kind. 2d. From abnormal thickening of the bones of the skull which sometimes obtains in rickets. In such cases the diagnosis may be made by a careful inspection and palpation of the bones of the head. The development of the skull is not uniform, it seems as if flat bumps had been superadded to the centre of the frontal and parietal bones, and we can detect with the finger the exact spot where the bone begins to thicken.† The swelling of the articular ends of the bones of the limbs which is characteristic of rickets, will at once awaken suspicion, for rickets and hydrocephalus do sometimes co-exist.

3d. From hypertrophy of the brain. This is an exceedingly rare affection, in which the head enlarges without exhibiting any symptoms at first; and when these show themselves after a time, they run an acute course which soon terminates in death.

Treatment should be persisted in for a long time, without the adoption of any violent measures. The plan recommended by Professor Gölis, of Vienna, seems to be one of the best. He advises the head to be shaved, and a scruple or two of mercurial ointment, mixed with ointment of juniper berries, to be rubbed on the scalp twice a day. The child should wear a woollen cap, to prevent the risk of the perspiration being checked by the cold air. From a quarter to half a grain

† Rilliet and Barthez.
of calomel should be administered twice a day; if it purges too much, the inunction of mercurial ointment must be alone employed. This treatment is to be persevered in for thirty or forty days, when, if there be some improvement, the remedies may be gradually diminished; but the cap is to be worn after the inunction has been discontinued. If there be no marked improvement after six or eight weeks, some diuretic, acetate of potash or squills, for example, may be added; and a couple of issues may be inserted in the occiput. Blisters to the nape of the neck may be advantageously substituted for these. Whenever there is heat of head, and the child grows fretful, restless, and irritable, a couple of leeches behind the ears will be found of service. Gölis affirms that under this plan of treatment he has known the circumference of the head decrease by half an inch, or an inch, in a period of six weeks to three months. He thinks that convalescence, when once begun, may be accelerated by small doses of quinine. Dr. Gower's plan of treatment, which is said to have been successful in many cases, consisted in rubbing ten grains of crude mercury with about a scruple of manna and five grains of fresh squills. This was one dose, and it was to be repeated every eight hours. The medicine induced great prostration of strength, loss of flesh, and profuse action of the kidneys, without ptalism. Chronic Hydrocephalus has been treated by two mechanical means: by bandages and tapping. Bandaging, which has been particularly advocated by Mr. Barnard, of Bath,* seems to be chiefly useful in pale flabby children, whose bones are loose and yielding: strips of plaster, about three quarters of an inch wide, are made to encase the head; they are to be applied circularly, transversely, and diagonally. Trousseau, who was at one time an advocate of this plan, has given directions for properly carrying it out in the Journal de Médicine, for April, 1843. But this eminent practitioner has good reasons for changing his views, and no longer advocates this plan. In his Clinique Médicale, second edit. p. 250, he says that he has given it up completely, since a child aged five months, whom he treated in that way, died suddenly on the fluid making its way through the æthmoid bone and the nasal fossæ.

The second mechanical mode of treatment, namely, by tapping the skull, and letting out the fluid accumulated in its interior, has been opposed by such men as Gölis, Richter, and Dupuytren. Dr. Conquest has been the greatest advocate of the operation in this country, and a paper on the subject may be found in the Medical Gazette, for March, 1838. Dr. Watson gives the sanction of his high authority to the procedure; and although Dr. West speaks rather doubtfully on the subject, yet he does not regard the operation as unjustifiable in some cases; when, for instance, there is good ground for believing that the hydrocephalus is external, or where the enlargement of the head has not been attended by indications of active cerebral disease. The operation itself does not seem to be attended with any very great immediate risks of life, if performed carefully. The best spot for

puncturing the skull is about an inch, or an inch and a half, from the anterior fontanelle, near the edge of the coronal suture, taking care to avoid the longitudinal sinuses, and some of the large veins which empty themselves into it. The trocar should be a small one, and it should be introduced perpendicularly. The fluid should be let out very slowly, and a few ounces at a time, and the skull supported by bandages, both at the time and subsequently. If the child turns pale and faints, a few drops of ammonia, or of brandy, will be found useful. If any inflammatory action should be set up a day or two after the tapping, cold lotion to the head and leeches behind the ears, and small doses of mercury will be required. The administration of iodide of potassium internally, and of iodine lotions to the scalp, has been advocated by Trousseau; and, when more active measures may not appear justifiable, some hope in the way of arrest of the further progress of the disease may be entreated from the use of these remedies. In addition to them I have found great assistance from the use of syrup of iodide of iron, cod-liver oil given in small doses, and bone-earth. The dose of cod-liver oil should be limited to a tea-spoonful, the object being not to increase, but to improve nutrition. The iodide of iron is usually very well borne by hydrocephalic children, unless there be a tendency to congestion, or to inflammatory action. Amongst the children of the poor the combination of the oil and the syrup of iodide almost always gives the most satisfactory results. Bone-earth mixed with fine sugar, administered with every meal, sprinkled on the surface of milk, or of other food, has appeared to me to possess a tonic action beyond that possessed by any chemical compound of the phosphates. It has an increased value in cases associated with rickets or imperfect nutrition of the bones; and a diet, of which lentil flour forms part, has appeared to be highly advantageous. Good food, given in limited quantities, and at small intervals, is absolutely necessary, and I object to the use of stimulants. When the patient appears faint and languid, beef-tea will prove a better and more permanent stimulant than wine or ammonia. The usual hygienic measures should be adopted,—warm clothing for the extremities, the head being kept cool. Bathing with sea-water is useful, taking care the limbs are rubbed to produce warmth and redness of the surface after the bath. The patient should, if possible, spend the summer months on the sea coast, or in some elevated district, and he should almost live in the open air.
MENINGEAL HÆMORRHAGE.

By J. Spence Ramskill, M.D.

The term, meningeal hæmorrhage is used to denote extravasation of blood, either into the cavity of the arachnoid, or beneath this serous membrane, and into the meshes of the pia-mater. Hæmorrhage occurring between the dura-mater and the bones of the cranium is extra meningeal, and, as it is usually the result of a blow or a fall on the head, in which case it often takes place on the side opposite to that of the injury, by contre-coup, it comes within the province of the surgeon and not of the physician.

In his valuable work on diseases of the brain, Abercrombie, at p. 238, relates a most curious instance of "extravasation in a cyst, formed by separation of the laminae of the dura-mater, from rupture of the middle meningeal artery." The patient, a man aged forty-eight, about the 12th of November, 1814, was assisting a neighbour to carry a heavy load up a high stair, when he felt a sudden attack of headache. He was from that time troubled with headache and giddiness, increased by stooping; and after these symptoms had continued rather more than a fortnight, he became sensible of some imperfection of vision. When seen by Dr. Gairdner, on the 2d of December, he complained of violent headache. The pulse was forty in the minute, and feeble. The pupils were at this time sensible to the light, but after a few days became insensible. He sank very gradually into coma, without any remarkable symptom, and died on the 13th. Inspection:—On the left side of the head, a cyst was found in the course of the middle meningeal artery, occupying the region of the lower part of the parietal, and upper part of the temporal bone. It was formed by a separation of the laminae of the dura-mater, and contained about four ounces of coagulated blood. The portion of the dura-mater forming the cyst was considerably thickened and very vascular. There was a depression on the surface of the brain, corresponding to the cyst, and the ventricles contained a considerable quantity of serous fluid. There was no other morbid appearance.

True meningeal hæmorrhage is an affection which is found generally at the two extremes of life, in infancy and old age. It occurs in new-born infants, after severe and protracted labours, and from the discoloration of the skin attending it, is often mistaken for cyanosis. It may be distinguished from this mal-formation, however, by the absence of cardiac murmur, which is almost always present in the latter.
The blood may be effused, as we have said, into the arachnoid sac itself, or under it, and in the pia-mater. A third variety has also been described, in which the blood is said to be formed between the dura-mater and the arachnoid; but recent researches have made it more than doubtful that the extremely delicate visceral layer of the arachnoid can be separated without being torn from the dura-mater.

Baillarger* has shown that the error arose from the rapid formation of a false membrane resembling the arachnoid, which isolated the effused blood. An instance of this variety, of traumatic origin, is related by Sir Robert Carswell. A man fell on his head, was stunned for some little time, but afterwards went to work as usual. Three weeks afterwards, he applied to a hospital, but was refused admission because he had no fever, and he was suspected of malingering. On leaving the hospital he drank some hot spiced wine on his way home, became delirious, and died in thirty-six hours. A post-mortem examination showed six ounces of blood effused between the dura-mater and the arachnoid, part of which was in a coagulated and part in a fluid state.

Two cases of the same form of hæmorrhage, but of spontaneous origin, are given by Andral in his "Clinique Médicale," occurring in two men, aged respectively seventy and seventy-three. Other instances are recorded by Rostan,† Blandin, Ménière,‡ Cruveilhier.§

Hæmorrhage into the arachnoid cavity.—This may be traumatic or idiopathic. When the latter, the blood accumulates in the cavity of the arachnoid, and is equally diffused over the brain, not accumulated at the base. It is generally more fluid anteriorly, and more coagulated posteriorly. The arachnoid and dura-mater are coloured by imbibition. After a time, the blood is enveloped in a pseudo membrane, and in old cases, cysts are found with yellowish contents and smooth walls; in some cases the two layers of the false membrane are found agglutinated, leaving no doubt as to the possibility of a perfect cure occasionally being made. With regard to the source from which the blood comes, there exists a discrepancy of opinion. According to most authors, the extravasation results from the rupture of a blood-vessel, but Prus|| maintains that intra-arachnoid hæmorrhage is always the result of exhalation. Hæmorrhage by exhalation is, however, a pathological phenomenon not accepted now-a-days, and for which cases of molecular rupture of blood vessels used to be mistaken.

SYMPTOMS.—In persons of advanced age, there are sometimes certain premonitory symptoms observed, in the shape of drowsiness, vertigo, general malaise, diminution of motor power, loss of speech, &c. All

---

† Rostan: Recherches sur le Ramollissement du Cerveau, p. 396.
§ Anatomie Pathologique du Corps Humain. Livre vi. viii. xvii.
these symptoms do not snow themselves in the same case, but one or other of them is generally present. Cephalalgia is a symptom which is usually met with in old people when hemorrhage has occurred.

Some authors regard the false membranes as being of inflammatory origin, and as the first step in the morbid process—the hemorrhage being only the second.* There may be such cases, doubtless, in the adult and the old, but that they are very rare, in children especially, is sufficiently proved by the suddenness of the symptoms.

There may be sudden paralysis of motion on the side opposite to that of the extravasation, and when this is considerable in amount, both sides of the body may be affected, or paralysis may begin in one side and extend to the other. Sensation is rarely affected. Motor paralysis is not a constant symptom, and deviation of the tongue and of one angle of the mouth, and strabismus, are of very rare occurrence in adults, whilst they have never been observed in children; according to Legendre,† paralysis occurs only in one out of nine cases; Rilhiet and Barthez say, in one out of seventeen.‡

Contractions, rigidity of the limbs, and convulsions are, on the other hand, almost always present. There is at first, somnolence, which gradually merges into coma, and this, when once established, persists, as a rule, unto the end. About the third or fourth day of the attack, there is intense fever lighted up, accompanied by the other symptoms of Meningitis.

The course of the disease is exceedingly irregular; death may take place suddenly, or only at the end of a month. The prognosis is not necessarily fatal, and according to Legendre serous cysts may be formed, which give rise to a form of chronic hydrocephalus. Hemorrhage may also occur beneath the arachnoid, between it and the pia-mater. In some cases, it may take place suddenly; in others, it may be preceded by some headache, drowsiness, redness and heat of the scalp and forehead. When the extravasation has taken place there is generally headache, but not very acute, and having no fixed seat. Paralysis of motion is rare, probably from the thinness of the layer of blood effused. It has been said that when the blood is derived from a ruptured artery, motor paralysis is more apt to occur than when it proceeds from a ruptured vein, the difference being explained by the rapidity with which the blood escapes from an artery, and the incidental shock to the brain. Sensibility is not affected as a rule. The intellectual faculties are merely enfeebled, not perverted. After a time coma sets in, which persists until death.

On inspection after death, which seems to be an invariable termination of the disease, the blood is found in a liquid state, showing no

‡ Maladies des Enfants, p. 257.
tendency to coagulate, or to form pseudo-membranes. From the fact
that no old cysts are ever discovered between the arachnoid and pia-
mater, it is inferred that sub-arachnoid haemorrhage is invariably
fatal. In his memoir on "Diseases of the Lateral Sinuses," Tonnellé*
has related instances of rupture of a sinus, giving rise to sub-arachnoid
extravasation of blood. In a case reported by Dr. Mullar,† the blood
came from the right lateral sinus which was ruptured at its point of
entrance into the torcular Herophilii: death occurred in twenty-four
hours, the symptoms preceding it having been those of cerebral
haemorrhage. According to Aitken, arachnoid haemorrhage occurs
when the extravasation bursts through the pia-mater and arachnoid
into the space between the membranes, and he says, such an affection
cannot be distinguished from ventricular extravasation. If, however,
the extravasation is immediately arachnoid at first, and of limited
extent, it may be approximately diagnosed; first, by the nature of the
symptoms having partaken of meningeal inflammation, such as by
severe pain in the head, with impaired intelligence and loss of power
of movement; second, the attack is less sudden than in cases of con-
gestion or of cerebral haemorrhage, and the symptoms are progressively
developed.

The following are the combinations of symptoms which indicate
sub-arachnoid haemorrhage:

First.—Complete and profound coma without paralysis, or with
general paralysis slightly developed.

Second.—Complete loss of consciousness without paralysis, but com-
bined with rigidity or clonic contraction of limbs.

Third.—Paralysis of hemiplegic distribution, as regards the limbs;
but without deviation of the features, the muscles of the face not
being implicated.

Fourth.—An apoplectic attack without anæsthesia.

Fifth.—Imperfectly developed coma with general paralysis.

Sixth.—An apoplectic attack, of which the symptoms are somewhat
interchangeable or remittent.‡

The Treatment of arachnoid haemorrhage must be guided by
symptoms present. When there is perfect coma with a full, hard pulse,
which is possible, a hot head, flushed face, turgid veins of the neck,
and a hot general state of surface, with a slow, deep respiration, we
may open a vein and take away ten ounces of blood with advantage;
but in by far the majority of cases there will be no such opportunity.
If the tendency be to death by syncope, the pulse small or feeble, the
surface cold, the face pale and head cool, if there be signs of disease
of the aortic or mitral valves, of kidney disease, or a general appear-
ance of anæmia, we should do mischief by abstracting blood. The
administration of a turpentine and castor-oil enema, and the applica-
tion of an ice-cap or cold lotion to the shaved scalp, will generally

MENINGEAL HÄMORRAGE.

limit our power of treatment, until the period of shock has passed away, or until consciousness has returned. Then the propriety of applying leeches must be measured by the degree of pain in the head, and of heat of the scalp. In the majority of cases even this will be found unnecessary. Free purgation will always be advisable, and the continued application of cold to the head. After a time, if the patient survives, the continued administration of the Iodide of Potassium promises the most hope of good. With respect to the abstraction of blood, it is right to say that the most eminent authority in Paris, Professor Trouseau, never sees any reason to order it. He denies the slightest advantage to be gained by it, either in arachnoid or in any other cerebral haemorrhage.

ADVENTITIOUS PRODUCTS IN THE MENINGES.

Under the head of Syphilitic Meningitis the presence in the dura-mater of so-called gummata has been adverted to. Calcareous deposits are also sometimes found in the substance of the dura-mater; in some cases the falx cerebri has been found completely ossified.

Hämatoma of the Dura-mater is hardly recognizable during life. The symptoms, according to Aitken, extend over several months, and consist in general weakening of memory and of intelligence, the occurrence of giddiness, and local pain in the head. A chronic form of idiopathic inflammation of the dura-mater is set up. At a later period an aggravation of all the symptoms occurs with transitory losses of consciousness. Somnolence and apathy prevail, and generally one-sided paralysis of the extremities, which may soon disappear; eventually the case terminates with symptoms of apoplexy. On post-mortem examination, sanguineous and flattened masses, composed of fine layers of fibrine, spread to a greater or lesser extent over the dura-mater, are discovered, accompanied by small extravasations which are converted into pigment. By repetition of the process, numerous layers come to be deposited one on the other. Numerous and larger blood-vessels form in these layers; and from these vessels renewal of the haemorrhage occurs (Virchow, Weber). The lesion is sometimes described as due to intra-meningeal apoplexy, with false membranes on the dura-mater; but the false membranes, which are the result of chronic inflammation, precede the apoplectic phenomena. The hæmatoma often attains considerable size. It may be four to five inches long, by two and a half broad, and one-half to three-quarters of an inch thick. It is generally of a flattened circular form, with a central elevation. The long diameter is parallel to the falcaliform process. The tumour generally occurs on one side only, or if bilateral, one is more developed than the other. The affection occurs only in the adult, and usually after the age of fifty. It has been clearly made
out that the hæmorrhage which gives rise to the formation of the hematoma takes place between the layers of false membranes, and becomes encysted there. Treatment must be tentative. Iodide of potassium is our chief remedy. Any symptoms which indicate a recurrence of the chronic inflammation must be met by the application of cold to the forehead, by purgatives, and revulsives. If we can succeed in preventing the recurring attacks, there is fair ground for believing the newly-formed membranes may undergo a retrograde change, and finally disappear.

Tumours have not been unfrequently found springing from the dura-mater, varying as to their character and the nature of their contents. They are sometimes fatty and encysted, and have been known to contain hair; and Morgagni (in Epist. Anat. xx,) speaks of an adipose tumour with hair in the substance of the tentorium. But sometimes also the tumour is of cancerous nature, constituting what has been termed "fungus of the dura-mater." The celebrated French surgeon, Louis, has written a most important series of essays on the subject published in Mém. de l'Académie de Chirurgie, vol. v. p. 1, Paris, 1774. The cancer may be of the encephaloid, or of the scirrhous variety: the former is the more frequent of the two, and indeed, when the tumour has made its way outwards by perforating the bones of the skull, it has often been mistaken for hernia cerebri. The tumour may spring from the outer or the inner lamina of the dura-mater, and in some cases there may be tumours co-originating on both surfaces of the dura-mater, as in cases reported by Chelius and by Dr. Bright. When they spring from the inner surface of the dura-mater, they have a tendency to grow inwards and depress the surface of the brain. But in comparatively rare cases they press on the skull, cause absorption of its substance, and protrude externally. In one case, described by Cruveilhier, protrusion had actually occurred; in another, perforation was in progress. In connexion with the dura-mater, are sometimes also found fibrous tumours, which, on microscopical examination, are seen to possess the same curvilinear stromal arrangement as the common uterine fibrous tumour.

The bony plates found on the inner side of the dura-mater have, by some, been regarded as growth belonging to the arachnoid, but that they are not so, is sufficiently proved both by the position in which they are found, and by the property of periosteal tissues, to which class the dura-mater undoubtedly belongs, to generate bone.

In connexion with the choroid plexus (that intra-ventricular appendix of the pia-mater) the adventitious products found have been indurated yellow bodies, the remains of former hæmorrhagic effusions, and more frequently round or oval bodies of a yellowish tinge, apparently formed of concentric lamina, which only become more apparent on the addition of acetic acid. They are generally microscopic, but sometimes accumulate into masses of the size of a pea or small nut. They have been called by Virchow corpora amylacea, and by Dr. H. Jones concentric corpuscles.
Small cysts are also pretty frequently found on the choroid plexus, which have by some been erroneously spoken of as hydatids, but there is no evidence to show that they belong to those parasitic formations. They rather seem to be due to a condensation of the epithelial covering of the plexus, and an accumulation of fluid beneath it, limited by an effusion of plastic matter.

CONGENITAL MALFORMATIONS OF THE MENINGES.

The dura-mater is the one generally affected, and such cases are of extremely rare occurrence. Sometimes the falciform process is entirely or partially deficient, as is also the tentorium.

The falx is, of course, absent when the cerebrum is undivided; or if the cerebrum be single in front and divided behind, the falciform process begins to appear where the division is, namely, at the coronal suture. In monsters, in which the posterior lobes of the cerebrum are deficient, the tentorium is also deficient. In a girl, seventeen years old, who was idiotic and motionless from birth, the hinder part of the tentorium was deficient.* The Reports of the Pathological Society, 1847 and 1848, p. 178, contain the account of a very rare defect of the falx cerebri exhibited by Mr. Shaw. Dr. Bright also gives a similar case, in which no trace of the process was visible anterior to the tentorium, and it was assumed that the defect, which occurred in a lady of thirty years of age, had existed from birth.

* Gilbert, in Edinburgh Medical and Surgical Journal, No. 95, April, 1828.
Addenda to Article on Simple Meningitis, p. 360.

Varieties as to Seat.—Meningitis may be partial or general. When partial, it may be limited to a small portion only of one hemisphere, generally the anterior lobe, or to the whole of one hemisphere alone; in that case, stopping abruptly at the median fissure, or it may affect the convexity of both hemispheres, or be restricted to the base alone. In some cases it affects the base, and the convexity of the hemispheres simultaneously. Meningitis of the base alone is, in the immense majority of cases, of tubercular origin. Parent-Duchâtelet and Martinet regarded very profound coma, not preceded by delirium, as characteristic of this variety of the disease; but Andral has conclusively shown that they were mistaken. As regards the relative frequency of the partial and general forms of Meningitis, Parent-Duchâtelet and Martinet say, that in ninety-one out of a hundred and seventeen cases, the inflammation affected the convexity of both hemispheres, and in twenty-six, one hemisphere alone.*

A very rare form of Meningitis is that which is confined to the membrane lining the interior of the lateral ventricles, a membrane which is so very fine and delicate, as to be indistinguishable when in a healthy condition, and the existence of which has even been denied by Kölliker. Andral relates five cases of this variety, in one of which the granular condition of the membrane pointed to its tubercular origin, a view which was supported by the presence of tubercles in one lung; whilst in another of these cases, the intraventricular effusion occurring in the course of general anasarca and ascites, was probably one of the results of albuminuria. The first case of the series, however, seems to be an instance of genuine inflammation of the membrane lining the lateral ventricles, which cavities were found after death to contain a sero-purulent fluid. The symptoms of this rare form of the disease do not differ from those of Meningitis in other parts. There is the same acute cephalalgia, generally referred to the supra-orbital region, followed by delirium and coma, and in some cases attended with violent agitation, convulsive movements, and tetanic rigidity of the limbs.

* Parent-Duchâtelet et Martinet : De l'Arachnitis, p. 94.
CONGESTION OF THE BRAIN.*

BY J. RUSSELL REYNOLDS, M.D., AND H. CHARLTON BASTIAN, M.D.

Under this name there are to be included several forms of disease very different from each other in the general character of their symptoms. In one of these the patient is feverish, and his attack is sometimes regarded as "brain fever;" in another the case is described as an "apoplectic" or "paralytic stroke;" in a third, as a fit, or seizure of "convulsions;" and in a fourth, as an attack of "delirium," or of "wandering." Patients taken with symptoms of disturbance, in any one of these forms, often die; and upon post-mortem examination there may be but one departure from healthy appearance of the brain, viz., congestion. We cannot but suspect that in many cases there have been alterations of nutrition which have escaped our notice, and that the locality and nature of such alterations have determined the form that the malady has taken. In others we may infer that, if the congestion has been the sole cause of symptoms, the character of the symptoms which accompanied it was determined by the situation of the excess of blood. But we cannot yet demonstrate the truth of these surmises or inferences, for we cannot see the brain while the symptoms last, and the most characteristic often pass away before the patients die. The premonitory, and even the earlier developed symptoms of cerebral congestion may be closely similar in many cases; they then speedily pass into one or another of the several groups enumerated above, and from the special characters which they then present the cases derive their names; but if the morbid state continue, and advance towards a fatal issue, the distinctive features of these several forms pass away; convulsion, delirium, and febrile action cease; and patients, who a few days before presented very wide symptomatic differences, look much like each other, and die in a similar manner. Such being the case, we should expect to find the traces of that which existed only a short time before death, and to fail in discovering evidences of those localized changes which must have determined the character of the previous symptoms.

It will be convenient therefore to describe first the premonitory symptoms of cerebral congestion, viz., those which are or may be common to its several forms; then to detail under four distinct categories the developed symptoms, with their modes of termination

* The sections on Pathology and Morbid Anatomy are written by Dr. Bastian.
in recovery; and lastly, to describe again generally those which are fatal, and into which any one of the four varieties may pass by a rapid or a gradual progress.

**Symptoms. A. Premonitory.**—There is often a mixture of two classes of symptoms,—those which indicate over-action, and the reverse; sometimes the two co-exist, at other times they alternate; in one case the former group is predominant, in another the latter; whereas in a few, all the symptoms tell in the direction either of inaction, or of undue excitement. It is possible sometimes to foretell from the nature of these symptoms, the form which it is most likely that the disease will hereafter assume; but such forecast is uncertain in all cases, and useful in only a very small proportion.

The mind is changed in such manner that there is diminished intellectual power; thought becomes confused, and memory treacherous; the individual may be irritable, "put out about little things," worried, fanciful, peevish, or depressed; sleepy, and especially so after meals, at times indifferent and sluggish; he complains that he "cannot think," and the forced effort to do so makes him worse; he talks at random, using wrong words—sometimes noticing his blunder, correcting it, and expressing his annoyance; sometimes not observing that he was wrong, and being greatly annoyed with any one who should attempt to set him right. He is usually worse after being in the recumbent posture, and after sleep; his sleep is heavy, and disturbed by dreams and nightmare; sometimes there are transient delusions—one person is mistaken for another—the past and the present are curiously intermixed, and the conversation is like that of a dream, a dream which goes on while the patient is awake, but from which he may be awakened still further by a loud voice or any other strong appeal to the senses.

The senses are dull: hearing is defective, and there are rumbling "noises in the head;" the sight is dim, and "black specks" appear before the eyes; sometimes diplopia is present; there is giddiness, and a feeling of oppression and fulness in the head, with "stupid headache," made worse by lying down. There is rarely "pain" in the head, but as the patients say, "a confused, uncomfortable feeling." The limbs feel heavy, and there is often numbness or "pins and needles" in the toes and fingers. These sensations come and go, but between the periods of their recurrence there is a sense of general discomfort which it is often quite impossible for the patient to describe. Often it is that of "oppression about the breathing;" and great difficulty from this source is experienced in walking upstairs, uphill, or even a little more quickly than usual on level ground. Sometimes "feelings of faintness" are complained of, and with them nausea and increased vertigo.

The power of movement is diminished, and with it yet more notably the readiness of action. The limbs are dragged along sleepily, or sluggish; the step loses its elasticity, is shorter than in health;
the "general bearing" is changed; and sometimes, but rarely, the alterations in power and activity are observed on one side of the body more distinctly than on the other. The patient simply leans forward, and appears weak and lethargic; or he may lean to one side, hold one shoulder half an inch or an inch higher than the other when standing, and when sitting collapse, as it were, on the lower side. Friends of such patients say, "He seems to go down on this side," and, "We are afraid that he will fall off his chair, or off the pavement," but the physician may observe no paralysis; for the stimulus given to voluntary effort by his presence is often enough to remove the trifling want of symmetry. The features are regular, the tongue is straight in its protrusion, and the grasp of the hand and the movements of the feet, are as pronounced on the one side as on the other.

There are other symptoms than those of direct change in the nervous functions, such as redness, and often dusky redness of the lips, conjunctive, face, and scalp. The head is hotter than the cheeks, the jugular veins are distended, and the neck appears thick. On stooping the veins of the forehead are too full, and the beat of the carotids is too distinct. The pulse is slow and laboured, or quick and feeble; the tongue is foul, the urine small in quantity, and often loaded with lithates; the bowels are confined, and the extremities are cold. The heart may be found dilated, and there may be tricuspid regurgitation, shown by the pulsation of the jugulars, and systolic murmur at the ensiform cartilage.

These premonitory symptoms may exist for very variable periods of time; may appear and disappear; or may gradually increase and pass into one or another form of malady already hinted at, but now to be described.

B. Developed Symptoms.—1. Apoplectic form.—The attack usually takes place during some muscular exertion, such as lifting a heavy weight, blowing the nose, coughing, sneezing, straining at stool, or stooping to pick up something from the floor. Sometimes it cannot be traced to any one of these, but it rarely occurs during sleep; patients do not wake up and find themselves in a state of what is called "congestive apoplexy." They are more commonly doing their ordinary work, or trying to do a little more than they are able to accomplish, when the attack is made. Consciousness, sensation, and power of motion seem to be lost, and the patient is said to have "an apoplectic stroke;" but these faculties are not altogether lost, or if they are it is for a few moments only, and the physician usually finds the following conditions:

The Mind is not in complete abeyance. There are indications that the patient knows, although but imperfectly, what is said to him; he makes some attempt to respond to questions, and to do what he is asked to do. He starts at a loud and sudden noise, looks round him, and gives signs of annoyance when he is disturbed. If at the moment of seizure he should appear to be in profound coma, this coma is of short, almost of momentary duration, and soon there are signs of return-
ing consciousness: there is confusion of thought, wilderment, and dulness of apprehension, passing sometimes into a mild delirium, but more often into a heavy sleep.

The senses, obtuse for a moment, are rapidly restored to a certain point. The patient shrinks from strong light, groans when pinched, starts when spoken to, but yet takes little or no notice of ordinary impressions.

The power of motion is so diminished that the patient falls down, and the limbs when raised fall heavily. All of them appear equally weak; but in a few moments, occasional voluntary movements may be seen in them, and these are commonly more distinct on the one side than on the other. There are slight twitchings of the muscles, but there is no rigidity. The features are usually symmetrical, or if drawn to one side are speedily set straight again. There is no stertor in the breathing; the speech is clumsy and the words are clipped, wrong words are used, but this is for a short time only; and the sphincters do not fail in their action.

The pulse at the moment of attack is sometime suspended at the wrist; and the breathing is arrested; but soon the pulse is felt to be heavy and laboured, and the respiration becomes tumultuous; and again, in a few seconds, both pulse and respiration go on as they did before. There is an exaggeration of the previous vascular fulness of the face, neck, and head; sometimes a bloodshot eye, or epistaxis; not unfrequently vomiting, with apparent faintness and a condition of collapse.

The symptoms of a first attack usually abate quickly; they may last for a few minutes, or for several hours; but most commonly they disappear within an hour; and the patient, although languid and perhaps alarmed, may feel better than he has done for some days before. Upon the repetition of seizure, however, the duration of symptoms is prolonged; the recovery of consciousness, sensation, and movement is less complete; drowsiness is more marked; and if there be some momentary awakening, it is momentary only; fresh attacks supervene, and each leaves the patient lower than he was before.

The apoplectic form of cerebral congestion is most common in advanced life, and has usually been preceded, and that to a marked degree, by the "premonitory" symptoms that have been described.

2. The convulsive form. The paroxysms that occur have the general features of epilepsy, described at p. 277; but they differ from the attacks of that disease in their general history and mode of onset. Congestive convulsions may occur at any period of life, but they are most frequently met with at the time of full maturity, or when that stage is passed. There are usually the premonitory signs of congestion, but these may be very slight; there may be no forewarnings, and the patient may be seized during sleep, or while making some unaccustomed effort. When the attack occurs during sleep it is difficult, and sometimes impossible to "say in what manner it com-
CONGESTION OF THE BRAIN.

menced; but when it has come on while the patient is awake and friends are about him, it has been usually observed that much discomfort has preceded it, for a few seconds, minutes, or hours. A tight cravat, worn while making some undue exertion; a sudden alarm; or an indigestible meal, rapidly swallowed, may be the immediate antecedents. The patient, more or less suddenly, becomes confused, then apparently half unconscious, makes some unintelligible sounds, turns red and then blue in the face, staggers for support, looks round him wildly or imploringly, and then sits down, convulsed, and a paroxysm, epileptiform in character, supervenes. From this he recovers partially, exhibiting great confusion of mind, headache, muscular feebleness, and sometimes partial paralysis of one side, or of one limb. The attack is occasionally followed by quasi-maniacal excitement, lasting from half an hour to three or four hours; after which, the patient becomes exhausted and falls into a heavy sleep. From this state he may recover, or during sleep a second or third attack of convulsions may come on.

When congestion of the brain has assumed this convulsive form, the patients, so far as my own experience extends, have usually been in middle life, and have recovered. But in other instances, when the age has been further advanced, the attacks have recurred more frequently, the intervals between them have become of shorter duration; and the patients—less sensible and less reasonable after every paroxysm—have presented the appearance of those whose attacks have been apoplectiform at their commencement.

3. Delirium may be the most marked symptom of congestion of the brain in certain cases. This is observed almost exclusively in those who are of an advanced age, but it is not absolutely limited to the period of senility. It may occasionally be met with in middle or even early life, and is then commonly accompanied by some change in blood-quality. The attack may come on suddenly, may be induced by a fall or a fright, but when occurring spontaneously is first observed towards evening. Sometimes the attack is preceded by "depression of spirits;" the patient, after some hours, or even days of undue taciturnity, becomes cheerful, or gay, and hilarious; he talks loudly and incoherently, but rarely exhibits any violence. He gets out of bed, wanders about his room or ward, opens drawers, puts on his dress, and is bent upon doing something which he cannot explain, or which, if expressed in words, is unnecessary, unaccustomed, and absurd. He is under a delusion, of no fixed character; and can usually be directed and managed without much difficulty. Sometimes, and this is especially observed in the aged, there may be hysterical crying; or still more rarely, great irritability of temper and some attempts at violence. The latter occur almost exclusively as the result of bad management and rough thwarting of the delusive purpose.

The patient may complain of pain in the head, or of uneasy sensations in the limbs; and there may be twitching of the muscles,
or weakness of the extremities. But none of these are complained of while the delirium lasts, although weakness and clonic spasm may be observed at the time of its occurrence. It is when the delirium has completely or partially subsided that these things are noticed, and that the general phenomena of cerebral congestion, viz. those which are described as premonitory symptoms, may be observed. Durand Fardel states that it is common to find "a mucous secretion, clear and viscid, produced on the eyelids, or in the interior of the mouth, and sometimes in extraordinary abundance, running over the whole face";* but this is very common in other diseases of old people, and has no special relation to mere congestion of the brain.

The recurrences of delirium may be very frequent or very occasional; some old people present them nightly for many weeks, and know nothing about them on the following days; while others exhibit them after much longer intervals, and only when "upset" by the little occurrences of the day. The tendency, however, is towards increase—not so much in degree as in persistence of mental change—and the patients become gentler, but less rational. The mind is weakened at each onset of delirium, and does not recover itself; there is drowsiness in the daytime and wandering talkativeness at night; but the intellectual powers are seen to be failing day by day; the physical energy diminishes, and the patient keeps his bed, and gradually passes into the state hereafter to be described.

4. Febrile form.—In the earlier periods of life, and especially in infancy and childhood, congestion of the brain may occur with marked elevation of temperature, a dry skin, thirst, and the restlessness and malaise of a pyreptic state. There is headache, not of great intensity, but of dull, oppressive character; the head is unduly hot, the cheeks and conjunctivae are flushed, while the extremities are cold; the mental faculties are obscured, and the sleep is broken by dreams or transient and mild delirium. Usually there has been some distinct cause for such disturbances; there is no marked prostration, no initial rigor; there may be some vomiting, but it is not persistent, nor are the bowels obstinately confined; there is no photophobia, no intolerance of sounds, no eruption on the skin; the secretions may be foul, but they present no indications of organic disease; and the patients usually recover speedily. Recovery is, however, not always observed; the distress may persist, there may be, alternately, convulsions and delirium, or there may be the changes from over-excitement to drowsiness, the latter gradually becoming relatively more marked, until the patient passes into a state of stupor from which he may never rally.

C. Final symptoms.—Under whatever form congestion of the brain may primarily appear, its tendency, unless speedily recovered from, is to produce a condition of torpor and inactivity. The mind becomes a blank; there is sometimes profound coma, stertorous breathing, and involuntary evacuation of both bladder and rectum; sensibility both general and special is lost, and voluntary muscular power reduced

* Maladies des Vieillards, p. 27.
CONGESTION OF THE BRAIN.

419
to a minimum. Convulsions may occasionally disturb the calm, or there may be fitful and momentary muttering of unintelligible sounds, but usually, in this latter stage, the patient lies quietly, with laboured pulse and breathing, and with flickering contractions of the muscles of the limbs until he dies.

CAUSES.—Among the predisposing causes must be reckoned such physical confirmation, as should impede the return of blood from the head, and the most important of these is a morbid condition of the heart. Dilatation of the right side of the heart, with loss of both power and valvular competency, are commonly found, during life and after death, in those who succumb to cerebral congestion. It is in old age that such changes are usually discovered, and hence advanced age appears as a predisposing cause. It is more common to find severe cerebral congestion in men than in women. Sedentary occupation, and shortness of neck, have been reckoned among the predisponents, but I think with insufficient reason; for attacks of cerebral congestion often occur in those of active habits and of healthy build, and indeed sometimes the worst forms of seizure that I have witnessed have been in persons of great mental and physical activity, in those who have been over-wrought, and who have continued in forced exertion beyond the bounds of reason and habitual practice.

The determining causes are to be found in all those conditions which entail sudden changes in the circulation. These are exposure to extreme heat or cold, and especially to the direct influence of the sun’s rays; blows upon the head or trunk; violent exertions, such as make it necessary to “hold the breath;” rarefaction of the air, such as is encountered in balloon ascents, and in some mountaineering expeditions; violent emotion, or prolonged mental effort; an over-loaded state of the stomach, and especially after undue abstinence; the ingestion of large quantities of alcoholic stimulants; a sudden change of posture, such as stooping or lying down with the head too low; and tightness of the dress around the neck.

Besides the so-called predisposing and exciting causes of cerebral congestion, there are two general conditions of the organism which may have some causative relation to the symptoms, although neither of the preceding words fully conveys the nature of that relation. A full-blooded, lax-fibred and fat man, in middle age, represents one of these conditions; a thin, pale, wiry old person, with rigid vessels, is an example of the other. Both are prone to suffer from disturbances, irregularities, inequalities in the circulation; and in either there may be cerebral congestion in a grave or fatal form. If these conditions be regarded as “predisponents,” it must be remembered that they have no special relation to this locality of congestion, and further that the mode in which the one operates is quite distinct from that in which the other leads to its results. In the former cerebral congestion is but part of a general condition, and some accidental posture may determine that the brain shall be the organ upon which the weight of
the burden falls; in the latter, feebleness of circulation-power, and locally increased resistance in the walls of vessels, may be the main factors in the production of such partial congestion of the brain as shall give rise to an apoplectiform seizure.

Diagnosis.—Remembering the general character of the symptoms which were described as “premonitory,” there can be but little difficulty in carrying the diagnosis up to a certain point, and in explaining them by the fact of congestion; but when the malady passes into either one of the four forms of “developed” symptoms, the diagnosis is sometimes difficult, and it is therefore necessary to consider it in detail with regard to each.

The apoplectic form of congestion resembles cerebral haemorrhage, acute softening of the brain, urinæmia, and syncope. From haemorrhage it may be distinguished by the facts of its less sudden onset; its occurrence while the patients are awake rather than when asleep,—patients do not wake up in the morning and find themselves paralysed on one side, as they often do in cases of haemorrhage,—the attack of “congestive apoplexy” occurs during the day, and its onset is observed;—by the equality of disturbance usually noticed in regard of mind, sensation, and motility at the commencement of the seizure; each of them is affected generally, and to nearly the same degree, but in no one direction is there entire and absolute loss of function except for a few moments; by the subsequent relative proportion of symptoms, such for example as partial paralysis of all the limbs with imperfectly-developed coma, a combination not to be observed in haemorrhagic apoplexy; by the speedy restoration of the mental faculties; and by the equable and usually simultaneous removal of other symptoms.

From softening of the brain in its acute form, congestive apoplexy cannot be always distinguished at the outset, for in some cases of the former the attack is in reality due to the occurrence of the latter. The diagnosis can only be made after some little time has elapsed, and then it will turn upon a recognition of the following points:—In congestion the mind speedily recovers, in softening it does not; in the former there is widely distributed but imperfect paralysis, in the latter, limited, but more complete, loss of power; in the one the patient is generally powerless, in the other he is hemiplegic; in the one there is flaccidity of muscle, in the other there is rigidity; in the former the premonitory symptoms have been those of congestion of the brain, in the other those of chronic disease elsewhere and loss of power.

From urinæmia the attack may be distinguished by regard to the premonitory symptoms; by the absence of œdema of eyelids or of lower extremities; by the absence of albumen from the urine; by the absence of marked rigidity of muscles; by the nature of the coma, its momentary profundity, rapid diminution, and want of that peculiar character which often attaches to blood-poisoning, viz. its apparent profundity in strong contrast with the ease with which the patient may be awakened up to a certain point; and further by the absence
CONGESTION OF THE BRAIN.

of a peculiar variety of stertor occasioned apparently in the mouth or at the palate.

From syncope congestive apoplexy may be distinguished by an examination of the heart, and the pulse at the wrist, the carotids, and the temples; by the colour of the face and head; the premonitory symptoms, and the conditions which led to the attack.

The convulsive form of congestion may be confounded with epilepsy or with eccentric convulsions. From epilepsy the diagnosis may be made by a consideration of the previous history; in the one there have been the premonitory symptoms of congestion, in the other no such phenomena have presented themselves; in the former the patient is usually of middle or advanced age, in the latter he is young, and is either under twenty years, or has not far exceeded that period of life; in the one the period of most marked congestion is at the moment of onset of the seizure, in the other congestion of the face and head is most marked as the attack is passing off; in the former there may be some moaning sound, in the latter the "epileptic cry;" in the one there is the sudden onset of an acute disease, in the other the attack of a chronic malady.

From eccentric convulsions it is possible to distinguish congestive convulsions by regard to age, and attendant symptoms. Eccentric convulsions are observed in infancy and early life and when some definite source of irritation can be discovered in certain organs of the body; they are found most commonly in the weak, irritable, and nervous subject, and they are attended by no premonitory symptoms of congestion, and by little or no evidence of its presence during the attack. There is but trifling somnolency, and the seizures differ from those of epilepsy and of congestive convulsion in not passing through the stages which were described as proper to the former, and which are closely simulated by the latter.

Congestion of the Brain in the form of delirium is met with almost exclusively in old age; and it is necessary only to mention delirium tremens in order to prevent the possibility of their being confounded. From senile softening of the brain, when this is accompanied by recurrent delirium, the diagnosis may be made by regard to the intermediate state; for when only congestion is present the patient returns to his normal condition in the intervals of wandering, whereas when the brain tissue is undergoing degeneration, and is the cause of delirium, no such recovery is possible. There is, moreover, a progressive enfeeblement of all the nervous functions, and a general condition of depraved nutrition such as is not necessarily found in cases of congestion.

The febrile form of congestion may be distinguished from meningitis by the absence of acute pain, and of intolerance of sensorial impressions; by the milder character of the delirium, the dilatation rather than contraction of the pupils, the absence of persistent vomiting, and of obstinate constipation, the generally milder character of the symptoms and their early cessation.
Pathology.—The circulation through the cerebral vessels has been supposed to present certain peculiarities owing to the brain being inclosed in an unyielding case, and being, therefore, beyond the influence of atmospheric pressure. This was first alluded to by the second Momro. It was supposed that no great alterations could take place in the total quantity of blood within the cranium at different times, although there might be an altered ratio, as regards the respective amounts of arterial and venous blood. It was even held by Dr. Kellie, that in animals which have died from haemorrhage there is no lack of blood in the brain; that where, on the contrary, we should expect to find a condition of cerebral hyperaemia we do not meet with it; and that the quantity of blood in the cerebral vessels is not affected by gravitation, and thus is uninfluenced by the position of the head with respect to the body. These views have also been supported by Dr. Abercrombie and by Dr. John Reid;* though they have been ably opposed by Dr. Burrows† and Donders,‡ many of whose experiments go to establish the direct reverse of the results arrived at by Kellie. It seems by no means satisfactorily demonstrated that the contents of the cranium are so entirely removed from the influence of atmospheric pressure. Dr. Burrows says: "The numerous fissures and foramina, for the transmission of vessels and nerves through the bones of the cranium, appear to me to do away with the idea of the cranium being a perfect sphere like a glass globe, to which it has been compared by some writers." And the other dogma on which this hypothesis rests, and which Dr. Abercrombie supports when he says, "we may safely assert that the brain is not compressible by any such force as can be conveyed to it from the heart through the carotid and vertebral arteries," seems to be directly contradicted by a consideration of other facts.§

The observations of Robin,|| and of His,||| who have discovered a system of lymphatic sheaths inclosing spaces around the cerebral blood-vessels, are of great importance, and reveal a structural adaptation which seems especially calculated to permit of varying amounts of fulness of the cerebral vessels, within certain limits, without injury to, or compression of the surrounding nerve pulp. Professor His has succeeded in injecting this system of perivascular canals, and has found them most numerous in the grey matter of both brain and spinal cord. He has found the injections come to the surface of the encephalon and cord, and fill a vast system of lacunæ situated between the pia mater and the surface of the nervous centres; whilst, if pushed still further, he has found it fill the lymphatics of the pia mater itself. Thus there is, as it were, a second series of vessels inclosing

CONGESTION OF THE BRAIN.

and surrounding with a fluid medium all the ramifications of the cerebral and spinal vascular system, whilst these two sets of vessels, containing and contained, are lodged in definite cylindrical canals permeating the nerve substance in all directions. The lymphatic sheaths are in contact with, though easily separable from, the walls of the canals through the nerve substance, in which they are contained. The diameter of these canals, and therefore of the lymphatic sheaths, may be seen in transverse sections to be generally twice, and sometimes three or four times as large as that of their contained blood-vessel. It will be easily understood that these two systems must have such a complementary relationship to one another, that an extra fulness of the one set of vessels must correspond with diminished fulness of the other set. That is to say, in order to make room for an increased amount of blood in the cerebral vascular system, a corresponding amount of fluid must be driven out of the enveloping lymphatic vessels;* whilst, when the vascular supply is again diminished, a proportionate amount of fluid re-enters the cerebral lymphatic canals.

Thus, we believe observation and experiment alike show that the amount of blood existing within the cranium may be subject to great variation, and that the peculiarities of the cerebral circulation have been much overrated.

The conditions capable of bringing about a state of cerebral congestion are very various, and so also is the degree of hyperæmia met with, and the extent of its diffusion over the encephalon. In one class of cases, the congestions seem to be more strictly mechanical phenomena, due to some impediment to the proper return of blood from the brain, owing to diseases of the heart or lungs, to pressure upon the great veins by tumours, or to their obliteration by thrombosis. In other instances, however, the condition of hyperæmia seems a more purely vital phenomenon, as when it is the result of prolonged study and over-mental work, or when it has an irritative origin, and is set up around some old clot, bony exostosis, or adventitious product in the brain. Then, alcoholic intoxication, great elevations and alternations of temperature, exposure to the sun’s rays in hot summer weather, and the suppression of accustomed fluxes, whether menstrual or other, are all looked upon as occasional causes of cerebral congestion. It is met with sometimes in the course of the acute specific diseases, and, in connexion with inflammation of the meninges, congestion is doubtless the initial stage of what afterwards becomes diffuse superficial cerebritis.

Cerebral congestion is most intimately related to cerebral hemorrhage on the one hand, and to inflammation on the other. Hæmorrhage is most likely to be associated with the congestions of mechanical origin, especially if these are brought about rapidly; and although such cerebral conditions generally give rise to well-marked brain symptoms, still the groups of symptoms previously described are usually related to congestions of a more active kind—such as are commonly spoken

of as 'determinations' of blood to the head—and which may be said to commence rather on the arterial than on the venous side of the circulation. In these cases, perhaps by virtue of certain changes occurring in the nerve tissue itself, an increased flow of blood takes place to the brain, which may subside after a variable time and after the production of a certain set of symptoms, or which may occasion the death of the patient after the superintervention of symptoms of a graver type. In certain other cases the congested condition of the membranes and cortical substance may gradually lapse over into a state of inflammation and be associated with tissue changes of a more marked character.

**MORBID ANATOMY.**—Congestion of the brain is almost invariably associated with a similar condition of the pia mater, and the amount of cerebral congestion is often judged of, in a loose way, by the degree of fulness of the vessels of this membrane. What many would consider a state of congestion is, however, natural to the vessels in this situation. Hasty opinions on this subject should, therefore, be especially guarded against. This fulness of the vessels of the pia mater is most notable in the occipital region, whether the blood gravitates, for the most part after death. Occasionally, however, as suggested by Laborde, this occipital congestion may take place during the last days of life, so as to place it in the same category with hypostatic congestions of the lungs.

In some cases where there has been every reason to believe that a state of congestion existed during life, it must be confessed that little or no traces of it can be recognised after death; though, on the other hand, when it has existed for some time and has been carried to an extreme degree, or when it has been often repeated, undoubted evidences of the present or previous existence of such a condition may be met with. In young and middle-aged subjects, in whom no atrophy of the brain has taken place, where there has been an extreme condition of congestion during life, the brain seems, after removal of the calvaria, almost too large for the cavity which contained it. The dura mater is seen to be tightly stretched over it, and on reflecting this, the convolutions appear broad and flattened and the sulci less obvious, from the effects of pressure against the interior of the skull. Then, there is not only the usual fulness of the large veins of the pia mater, but also a more tortuous and even varicose condition of these trunks, together with a more complete injection and turgescence of the smaller vessels than is usually encountered. The membranes may be stripped off the surface of the convolutions without tearing the grey matter, and on section this appears darker than natural, and dotted with bloody points in the situations of its loaded vessels. The white substance also shows an abundance of red points; and gorged vessels are pulled out for a certain distance from the cut surface. These are only comparative signs, however, and their true value must be estimated accordingly, since all intermediate
CONGESTION OF THE BRAIN.

conditions may be met with between the ordinary healthy amount of fulness, and the most marked degree of hyperæmia. It is extremely difficult to draw the line and say what is morbid, and what consistent with health.

If, however, the congestions have been often repeated or have lasted for any length of time, microscopic examination does enable us to discover evidence of this. The capillaries, and more particularly those of the grey matter, become twisted and varicose, displaying partial dilatations, or real aneurysmal swellings, implicating either a part only of the calibre of the vessels, or dilating them in numerous adjoining parts in their whole extent, so as to constitute “l’état moniliforme” of Laborde. But a still more certain mark of old congestion is afforded by the presence of a quantity of blood pigment (hæmatine) surrounding the vessels, though inclosed within the lymphatic sheath described by Robin. It is met with in the form of more or less rounded grains, which are mostly of large size, and may be as much as 3000 in diameter. They are usually of a dark olive, or amber yellow colour, and are composed of a number of minute pigment granules aggregated into small spherical masses, in the same way as the little fat particles composing an ordinary granule corpuscle. The pigment remains quite unaltered after the application of ether, alkalies, or the strongest acids. The crystalline form (hæmatoidine) is not met with, since this seems to be produced only in places where an actual extravasation of blood has taken place, whilst the pigment in this granular and amorphous condition seems to result from stasis of blood, and more or less transudation of colouring matter, or hæmatine, through the walls of the vessels into the surrounding lymphatic canals. It seems impossible otherwise to account for what I have seen. I have found, for instance, this matter in great abundance around almost all the small vessels and capillaries of the brain and spinal cord of two individuals. Both were lunatics; the one an epileptic and chronic maniac, subject to paroxysms of great excitement, and the other a chronic maniac of the most violent and excitable disposition whose fits of passion were both frequent and long-continued. It was in these individuals that this granular blood pigment surrounding the vessels first attracted my attention. I have found since that it had been noticed and described by Robin, and I can endorse his statement that a few such masses of pigment are usually to be met with, here and there, on the cerebral vessels of even young and healthy subjects. It is, therefore, the abundance of this matter only which is

1 "Le Ramolliss. et la Congest. du Cerveau," Paris, 1866. These irregular aneurysmal dilatations must not be confounded with the distinct microscopic aneurisms described by Bouchard as frequently existing in different parts of the brains of old people. We have previously hinted at the occasional connexion between cerebral congestion and cerebral hemorrhage, and now we may state that the links which bind the two together are frequently the minute aneurisms just mentioned. Congestion may have something to do with their formation, as it certainly has with their final rupture leading to effusion of blood. (Trans. of Path. Soc. vol. xviii. 18.)
to be looked upon as an index of disease; and the duration of past congestions may be roughly guessed at by the more or less excessive accumulation of pigment around the vessels.

Occasionally, however, an actual rupture of one of the minute vessels may take place under the increased strain upon its walls in cerebral congestion. This is all the more likely to occur in elderly people whose vessels have been weakened by atheromatous or other degenerations. In such cases I have not unfrequently found, after careful preparation, evidences of past capillary haemorrhages on several of the smallest vessels of the same brain. After the brain substance has been washed away, and when the vessels are floated in water in a shallow dish, one or more little orange coloured specks may be seen, even smaller than a pin's head. When examined with the microscope they are found to be accumulations of altered blood pigment in the form of amorphous canary-yellow flakes, interspersed with distinct crystals of hæmatoïdine, situated around one of the minute vessels, and distending its sheath in a more or less obtuse fusiform manner. In these cases the presence of the perivascular sheath seems to limit the amount of blood effused, since as soon as this becomes distended in the immediate neighbourhood of the rupture, the pressure so produced tends to close the aperture in the ruptured vessel.

Lastly, there is to be mentioned that condition of certain parts of the brain which was spoken of by Durand Fardel* as "l'état criblé," and which he and others regard as an evidence of previous dilatation of the vessels from long-continued congestions. This condition is occasionally well seen, more especially in old people, in the white substance immediately beneath the grey matter of the convolutions. On section a number of round or oval apertures appear—some large enough to admit a pin's head,—and within each may be seen the cut extremity of a vessel. In these situations the canals in the nerve substance have become enlarged by pressure, and the lymphatic sheaths have been dilated to a similar extent, whilst in the space between the sheath and the much smaller blood-vessel a large quantity of pigment granules is generally met with. This dilatation of the vascular canals sometimes reaches an extreme degree in the corpora striata and in the optic thalami, and the same condition is encountered, though to a less extent and less frequently, in the substance of the pons varolii. Whenever they are met with, however, the structural conditions and the mode of origin seem to be the same.

Durand Fardel says:—"Tantot l'état criblé du cerveau se trouve répandu dans une grande étendue des hémisphères, tantôt on ne l'observe que dans un espace circonscrit." This condition is found at all ages, though more particularly in old people, and in these latter, the same writer says, the canals are sometimes so large and numerous in the corpora striata, that these bodies seem to have lost nearly half their substance. Many of the facts connected with these canals, seem

* Loc. cit. p. 57.
to render it doubtful whether they are produced by the dilatation and pressure exercised by congested vessels, though others seem to make this method of pathogenesis most probable.

Prognosis.—In cases of cerebral congestion regard must be paid to the age of the patient, the form of his attack, the severity of the symptoms, and the frequency with which the symptoms or the attack of symptoms may have occurred.

Age cannot be fairly estimated by the mere duration of life, for some men are “older” at fifty-five than others are at seventy years, and are so without any necessary co-existence of exhausting, or definite disease. The apparent age is a truer guide than the real age in the matter of prognosis. Baldness, gray hair, rigid vessels, a weakened heart, arcus senilis, and enfeebled powers, must be taken into more serious account than the date of birth; and judged by such tests, the prognosis is unfavourable in proportion to the oldness or agedness of the individual.

The form of attack is worthy of most grave consideration. That which is of the worst omen is the apoplectic; next to this is that characterised by delirium; after it the convulsive form; and least serious of all is the febrile, or quasi-febrile.

The severity of symptoms is of much value in relation to the apoplectic form; the danger being in direct proportion to the profundity of coma, and its duration. It is of but little moment when delirium is the most prominent symptom, and the value that it possesses is in inverse rather than direct ratio to the force of the disturbance; the prognosis is worse when the delirium is mild, muttering, and continuous, than when it is noisy, or even violent, although—as is usually the case—of short duration. When convulsions occur it is not safe to base any prognosis on the mere fact of their severity; for often patients recover after the most frightful seizures, whereas others succumb to much milder paroxysms. The degree to which in the intervals of seizure, the mind is restored to its normal state, is a fairer criterion of the amount of danger than is the violence of the convulsion. In the febrile form the prognosis is bad in direct proportion to the intensity of the symptoms. When the disturbance is slight, confident hopes of recovery may be entertained; when it is severe, there is room for the apprehension of ulterior, and “inflammatory” changes.

Congestion of the brain is rarely fatal at its first attack; it becomes dangerous in proportion to the frequency and readiness of its induction; and this is true with regard to each form in which the symptoms may be developed.

The other conditions by which the prognosis must be determined are those of organic disease, or degeneration in any of the important vital organs. It is obvious that the heart, the vessels, the kidneys, and the liver should be examined with care, and that the opinion formed as to the future should be guided by the kind and amount of
disease that may be found in them. The prognosis, however, when such diseases are discovered is not that of cerebral congestion only, but of those complicated morbid conditions of which it is but one form of expression. It may be that congestion of the brain is likely to prove the cause of death, but the nature of the disease which leads to such congestion, furnishes the materials, by a consideration of which the probabilities may be estimated.

TREATMENT.—As there are two distinct, practically opposite, conditions of the body under which cerebral congestion may occur, so there are two different lines of treatment to be adopted. If the brain congestion be but one of many symptoms of a general plethora, much may be gained by either general or local blood-letting; if it be but the outcome of weakness and vascular obstruction, then such measures may increase the evil. The previous habits and health of the patient, the present state of his integuments,—their warmth, vascularity, and colour,—the state of the pulse, of the heart and vessels will furnish the guides in this important matter. A man in middle age, who has over-strained himself, or placed his head in some dependent position, and who is attacked by violent convulsions, characterised by great turgescence of the skin, bloodshot eyes, and a full but laboured pulse, may be relieved, and greatly relieved, by venesection to the amount of six or ten ounces. But such cases occur rarely, and in the majority of instances, no man would at the present day think of bleeding from the arm. When, however, there is distinct general weakness, and with this, heat of head, oppression, continuous headache, and a tendency to drowsiness, much relief may be obtained by the application of leeches to the temple, or by cupping to three or four ounces at the back of the neck. When there is no such heat of head, and no flushing of the face, but when the diagnosis of cerebral congestion may still be made—per viam exclusionis,—and when the vital powers are low, the pulse small, feeble, irregular, or intermittent, even a small abstraction of blood locally may be followed by the worst results. It is when attacks of congestion are frequently repeated, and other measures have failed to relieve them, that local depletion may be found of signal service.

It is well to raise the head, to apply cold water or ice to the forehead, and to place the feet and hands in hot baths. If the stomach be overloaded an emetic of mustard, or ipecacuanha may be given, and often with the discharge of the stomach the symptoms pass away. This is especially useful when the attack has followed a full but hastily taken meal. It is of great importance to empty the rectum, and the most efficient means for doing this is the administration of an injection of warm water. Should there be any suspicion of the existence of hardened masses of feces, the injection of a large quantity of warm olive oil will prove more useful than that of water.

When the tendency to cerebral congestion is noted, rather than any marked symptoms of its presence to a high degree, the secretions
must be carefully regulated, and among these one of the most important is the urinary. Many cases of threatening aspect are to be relieved by saline diuretics; and I have known a copious flow of urine to be followed by the removal of symptoms which had existed in spite of free purgation, and other treatment.

There are many cases occurring in advanced life in which the congestion is of only momentary duration; and the patient, when seen by the physician, is simply bewildered, pale, and with a cool, moist skin, and feeble pulse. Under such circumstances the cautious administration of stimulants is called for; and of these salvolatile and wine are the most useful. It is well to combine with them carbonate of potash, or of soda, as there is often considerable "acidity of stomach," and the discharge of flatus by the mouth, which results from such administration, is often followed by a complete remission of the symptoms.

As precautionary measures, quiet of mind, and gentle exercise of body, with the careful avoidance of either fatigue, sudden change of posture, or strain, should be enjoined; and much relief may be obtained by insuring a position during sleep, which shall prevent not only the head, but the head and shoulders from sinking down to the level of the body. This may be easily obtained by a simple contrivance placed under the bed or mattress upon which the patient lies; such an arrangement being much better than a mass of pillows, which shift their places, and often maintain the head in a condition of undue heat.
CEREBRITIS.

By J. Russell Reynolds, M.D., and H. Charlton Bastian, M.D.*

It is probable that general inflammation of the brain never exists alone, but that it is invariably associated with meningitis. The terms encephalitis, meningo-cerebritis, and phrenitis, which have been employed to denote the condition now referred to, are sufficient of themselves to point out this constant association. Nevertheless, in some cases there is to be found, during life, the predominance of a class of symptoms which simple meningitis will not account for; and, after death, the presence of such changes in the cerebral tissue, as do not necessarily accompany the meningeal inflammation. It would seem therefore, that the brain-substance is not only susceptible of morbid change under an inflammatory type, but that the presence of such change may determine the clinical history of the case. We may, in particular instances, refer some of the symptoms of a complex encephalitis to inflammation of the membranes, and others to an implication, in like change, of the cerebral tissue.

Meningitis has already been described, and it remains for us, in this place, to describe only those symptoms which mark the extension of the malady to the brain itself. All that relates to that which has been described as local cerebritis, or limited softening of the brain, will be found under the articles on Abscess of the Brain and Softening of the Brain.

Causes.—The most common causes are injuries to the head; such as violent contusions, wounds, diseases of the bone, and insolation. It would appear, however, that sometimes prolonged mental exertion, or moral excitement have led to the development of this disease. In rare cases there has been no distinctly recognisable cause, the symptoms having appeared in the absence of any one of the conditions above mentioned.

Symptoms.—These are, of necessity, associated with those of meningitis, but sometimes they are the earliest to appear, and are predominant throughout the case. Thus, some mental change may be the first evidence of disease; it may be very slight, and may be mistaken for "hysteria," "stomach disturbance," or some such vague malady. In one case, which I saw several years ago, there was a mere confusion of ideas, and a worried manner, with misuse of words, and this for two

* The section on Pathology is written by Dr. Bastian.
CEREBRITIS.

431

or three days before other phenomena appeared. Usually the patient is sullen, and the faculties are obscured; there is a confused, "muddled" state of the intellect, sometimes merging into mild delirium, sometimes, when meningitis is present, alternating with, or superseded by, violent excitement.

There is deep-seated, oppressive pain in the head, described as sometimes shooting from the centre to the vertex, the temples, eyes, or ears, and this pain is persistent, and is out of all proportion to the pyrexia, which is often very slight. Except in dependence upon meningitis, there is no intolerance of light or sound, but there may be obscurity of vision, diplopia, and failure of sight, together with ringing noises in the ears, and some difficulty in hearing.

There is general muscular lassitude, but neither definite paralysis nor spasm; the limbs are weak and aching, but they may all be moved.

Such symptoms may continue for two, three, or four days, and then a violent convolution may occur, followed by coma, from which the patient never thoroughly recovers. There is, however, partial recovery sometimes, and then more or less general paralysis is discovered. The patient is stupid, sleepy, comatose, and lingers for a shorter or longer time, in proportion to the amount of nourishment that can be given and retained by either stomach or rectum. Convulsions somewhat epileptic in character, usually recur, and in their intervals there is to be observed a gradual dying out of the various functions of the brain. Mind, sensation, and voluntary power are lost, and the patient lives a merely vegetative life, disturbed occasionally by slight spasmodic movements, or rigid contraction of the muscles. The convulsions are often of long duration, involve the limbs especially, and are not marked by notable asphyxia.

The general symptoms are, as a rule, so slight that they attract no notice. There is no fever, little or no vomiting, and no obstinate constipation of the bowels. Very often the sphincters are relaxed quite early in the history of the case, and nothing abnormal can be discovered in the evacuations.

Diagnosis.—That which gives to the diagnosis of meningitis its gravest element, is the recognition of co-existing cerebritis, and hence the diagnosis is valuable as an aid to prognosis. Cerebritis may be inferred when there is a rapid transition from the excitement of meningeal inflammation to the marked loss of function which is characteristic of cerebral change. When the signs of meningitis are unusually severe, the pain deep-seated, and followed after twelve or twenty-four hours by convulsions, coma, and paralysis, there is commonly Cerebritis of considerable extent.

Pathology.—Of uncomplicated Cerebritis we have no knowledge. When inflammation of the brain substance exists, it is either associated with a more marked change of the same kind in other parts, such as
the meninges, in which case it is treated of as a concomitant condition, and not as a primary morbid affection; or else it speedily lapses into other distinct pathological states, such as abscess or softening, which, on account of their importance, are usually treated of as independent affections of the brain.

Two kinds of Cerebritis are usually described, namely, the diffuse or general form, and local Cerebritis, which by most recent writers has been held to be synonymous with "red softening," or "acute ramollissement" of the brain.

The diffuse form, or general Cerebritis, is a more or less wide-spread affection of the cortical substance, or grey matter of the convolutions, and is always associated with inflammation of the meninges. It may be met with in surgical cases, from injury to the skull, when, conjoined with it, there is inflammation of the dura-mater and arachnoid, together with the formation of purulent lymph within the arachnoid cavity, and also beneath the visceral layer, into the meshes of the pia mater. Cerebritis may also be met with in the more limited meningitis, not of traumatic origin, which affects the pia mater principally, and which is not accompanied by purulent effusion into the sac of the arachnoid. In these cases, there is extreme vascularity of the cortical grey substance, which is also more soft and pulpy than natural, often of a leaden hue, and frequently adherent to the meninges, so as to be torn when these are stripped off. For further particulars we must refer to the articles MENINGITIS and TUBERCULAR MENINGITIS, under which heads is included an account of this condition, so far as it comes under the cognizance of the physician. It should be stated, however, that many pathologists of the French school look upon GENERAL PARALYSIS of the Insane as a disease due in part to a species of chronic cerebritis. The same adhesion between the grey matter and the meninges is frequently met with in this disease, but for further information we must refer to the article on this subject. See p. 36.

With regard to local Cerebritis, we think with Lebert and other pathologists, that this may be the antecedent condition and proximate cause of ABSCESS in the brain, and we do not deny, also, that some acute softenings of the brain may have an inflammatory origin. We do, however, strongly object to the view that all "red softenings," or "acute ramollissements," have to acknowledge this method of pathogenesis. We believe that most of the softenings hitherto placed in this category have been brought about by embolism or thrombosis, and consequent obstruction to the cerebral circulation, and that the characters, usually considered as diagnostic of their inflammatory nature, are capable of receiving a totally different interpretation, as may be seen by reference to the article SOFTENING OF THE BRAIN. In this view we are supported by many recent writers on the subject. With regard to the existence of softening of the brain of inflammatory origin, we do not deny it as a fact, only we plead ignorance as to the characters by which it is to be distinguished from softenings of a
different nature, and we believe it to be of infinitely rarer occurrence than is thought by many pathologists. It would seem most likely to occur in cases of wounds or injuries to the brain, or around adventitious products, as centres of irritation.

Prognosis.—The prognosis is as bad as it is possible to be. There is no probability of recovery when symptoms such as those above described have been developed.

Treatment.—Only palliative measures can be used with any advantage. I have never seen any good result from mercury, given by the mouth or by inunction; nor from blisters, cupping, or other modes of blood-letting. Pain may be relieved by the application of ice; and spasmodic movements may be limited by sedatives, such as belladonna and Indian hemp; but beyond such relief of symptoms therapeutic art has failed.
SOFTENING OF THE BRAIN.

By J. Russell Reynolds, M.D., and H. Charlton Bastian, M.D.1

Definition.—A disease characterised during life by impairment of mind, sensibility, and motility, and after death by diminished consistence, and degeneration of the cerebral substance.

The disease now to be described is that which has been known as white, or non-inflammatory softening; ramollissement blanc, or ramollissement non-inflammatoire.

Causes.—There is little that is satisfactory which can be said with regard to the etiology of softening of the brain. Among the conditions which predispose to its occurrence the most important is age, or agedness. Softening of the brain is essentially a manifestation of decay, and this may be either the natural result of the wear and tear of a long life’s work, or it may be the early outcome of excessive strain. The real cause is that waste of tissue which is unbalanced by repair, and this may come from the long continuance of work,—old age, —or the unhealthy severity of work, and its undue relation to rest. Neither sex, constitution, nor season of the year have been shown to exert any marked predisposing influence, nor has any distinct relation been made out between any one particular condition of the heart and cerebral softening. Degeneration of the kidneys and impaired nutrition of the heart and vessels are among the conditions which frequently accompany ramollissement; but these ought to be regarded as certain parts of a general change of which the cerebral softening is but another or a counterpart, rather than as predisposing causes of its existence. Vegetations on the valves of the heart may become detached and may block up one of the cerebral arteries; and thus their presence on the valves might be regarded as predisposing to softening of the brain. But it must be remembered that such vegetations when in situ, i.e. undetached, do not predispose to softening of the brain, that they may lodge in other vessels than those of the cerebrum, and that when they are carried from the heart to the cerebral arteries they become determining and not predisposing causes.

1 The sections on Pathology and Pathological Anatomy are written by Dr. H. C. Bastian.
If we may employ the term "predisposing cause" under these circumstances, we should do so to the general, or constitutional state that has led to the production of vegetations rather than to the vegetations themselves.

There is nothing definite to be said with regard to exciting causes. Attacks have sometimes followed violent mental or moral excitement, anger, abuse of alcohol, over-fatigue, or local injuries; but in the majority of cases no such conditions have been present, and in very many there has been a singular immunity from all apparent causes of disturbance. Exposure to cold has been followed by an apoplectic seizure, and one of the more frequent determining causes of an attack has been too free a purgation of the bowels.

**Symptoms.**—Softening of the brain may occur as either an acute or a chronic disease. It will be well, therefore, to describe the affection under two general headings, and first:

**Acute Softening of the Brain.**

1. **Premonitory symptoms.**—These may be absent altogether, but such complete immunity is rare; for softening of the brain most frequently occurs in those whose health has been, for some time, below the average; and very frequently in others who are the subjects of some distinct chronic and exhausting diseases. There is nothing so special in the character of the general condition which may precede softening of the brain as to render it of much value in the forecast of a patient's chances. There is often an enfeebled condition, with impaired nutritive power, shown in the general bearing of the patient, and more distinctly in the weakness of cardiac impulse, rigidity of arterial vessels, and local inequalities of temperature. These facts may be noticed for months, or even years, but there is nothing in them that points specially to the brain as the organ which is likely to give way. In combination with symptoms of cerebral failure they are, however, of great significance.

The symptoms which, when thus combined, are premonitory of softening, are those already described as characteristic of impending or actually developed congestion of the brain. (See p. 414, article Congestion of Brain.) They are,—headache, more or less constant in duration, and usually "dull" in character, dulness of sight or hearing, numbness, obscure pain, weight, or an indescribable sensation of "something wrong" in the extremities, slight confusion of thought, sleepiness, weakness of purpose, hesitation in judgment, irritability of temper, diminished control of emotion, deficiency of muscular power, a stooping gait, and tendency to cramps in the limbs. Sometimes the face assumes a dull, expressionless aspect when the patient is at rest, and he may pass hours in a state of apparent indifference to all around him; but when called upon to exert himself is able to resume his
habitual manner, and do his accustomed work, although with some heaviness of manner and apparent effort. There may be occasional and slight symptoms of faintness, the face becoming pale, and the limbs cool, and such occurrences are of much significance. It sometimes happens, moreover, that the altered sensations above described are noticed more on one side of the body than on the other, and the fact of this limited distribution is highly indicative of impending evil. There may be a little dragging of one leg, or only a tendency to lean to one side when either walking or sitting, and this, when constant in its locality, is of much graver meaning than is a much greater amount of weakness when variable in its seat.

Such symptoms may continue for a shorter or longer time, and may precede either acute or chronic softenings, and there is nothing in their nature, when existing only to the degree described, and which can alone be regarded as "premonitory," that furnishes any clue to the form which the developed symptoms are likely to assume.

2. The developed symptoms may occur in one of three distinct forms. The patient may either have an apoplectic seizure, be taken with convulsions, or may pass into a state of delirium; and it will be convenient to describe these forms separately, premising that sometimes they pass into one another, and that occasionally mixed cases are observed, in which apoplectic, delirium, and convulsions alternate.

(a) The apoplectic form may be very gradual or very sudden in its onset. When the former, there is an increase of the premonitory symptoms for days or weeks; when the latter, there may have been no special premonition, but the patient suddenly falls down in what is termed an "apoplectic fit," and he is said to have had "a fit," or "a stroke."

Very commonly the attack occurs after too long an abstinence from food, or when the patient is fatigued by too long a walk, or too protracted an effort; sometimes when, as in congestion of the brain (see page 415) he is making an excessive exertion. It is not common, so far as my experience extends, for patients to wake up in the morning and find themselves paralysed on one side of the body, a mode of attack by no means uncommon in the case of cerebral haemorrhage.

The condition of the mind is highly significant. Transient excitement, talkativeness, irritability, or wandering of thought, amounting sometimes to mild delirium, may occur for a few minutes. The patient says or does something quite out of relation to his surrounding circumstances or previous conversation; speaks as if to some person he may not have seen for years, asks a question which refers to events long since passed; or, in some other manner shows that he is "not quite himself," is bewildered and "queer," vexed or pathetic, he makes some effort to get up and do some extraordinary thing which no one can understand, is impatient of attempts at dissuasion or control, looks faint, and becomes more or less insensible, sometimes falling to the ground, sometimes voluntarily sitting or lying down, as if merely
fatigued, or disgusted with the stupidity of those around him, who do not understand what it is he wants to do.

The patient may for a few minutes be completely insensible, and when he is so, it is probably due to sudden congestion of brain, or to equally sudden anæmia of brain, either of which may be recovered from in a few seconds or minutes. When, however, the physician sees the case, he rarely finds absolute loss of consciousness. The patient lies quietly, in apparently profound sleep, snoring, and taking no notice whatever of the questions that friends ask in anxious and beseeching tones; but if spoken to sharply, told to put out the tongue, open the eyes, give the hand, or do any other simple thing, he responds at once, usually makes an awkward failure, and then relapses into his former state; if asked a question he makes some inarticulate or unintelligible sound in reply, and again falls back into his heavy sleep, sometimes muttering to himself, but more commonly snoring continuously, or occasionally interrupting the rhythm of his snore by a long-drawn sigh.

In such a state the patient may continue for hours, days, or even weeks. There is often sufficient intelligence remaining for him, when roused, to swallow food, to recognise friends, to make efforts to say something; but so much dulness of apprehension, and so much difficulty of expression, that the real life is "hidden," and it is impossible to know that we are on such common terms with it that we can understand its meaning.

Sometimes there is marked improvement, the faculty of articulation returns, and a certain amount of conversation is possible to and with those who will give pains to learn the language that is spoken. The names of common objects are forgotten, or are confounded with those of others; and this, sometimes with such constancy that friends may understand what is intended, sometimes with such thorough want of uniformity that the meaning is unintelligible. Notwithstanding this great obscurity of expression, it may be perfectly clear that the patient himself knows distinctly what he means, is aware that he is wrong in his use of words, is vexed at his blunders, and ingenious in contriving means to counteract or avoid them. For example, he may know so well the words which he wants, and which he supplies by others in ordinary conversation, as to write down lists of words, and point to one or more of them in order to make up his sentences, or correct erroneous expressions. (See page 443.)

Occasionally, after being even profoundly affected, the mental condition may undergo great improvement, and the patient, although not perfectly restored, be carried back again to the point described in the notice of premonitory symptoms. But far more commonly there is no real restoration; some confusion may clear away, the stupor may be lessened, but when these improvements have occurred the mind is found to be dulled, and incompetent, and in a state of gradually increasing deterioration; week by week, and month by month, the patient is further and further removed beyond the reach of intercourse, until
the attempts to talk with him are given up, so gradually by the friends that they are scarcely aware of the change, so imperceptibly to the weakening mind of the patient that he takes no notice. In this way a sudden attack of softening may pass into what is termed "chronic softening;" the patient becoming imbecile of mind, and powerless in body.

In a certain number of cases, the course is rapid, the apoplectiform attack is repeated, and at the end of two or three days there is profound coma, passing into the sleep of death; in a much smaller number, the symptoms are very transient, and the recovery may be complete. For example, a young lady at twenty-two, in her first attack of acute rheumatism, marked by considerable swelling and redness of knees, wrists, and ankles, and a recently developed systolic murmur at the base of the heart, received a visit from some friends, was excited in conversation, and had palpitation of the heart. A few minutes after her friends had left her she grew faint, looked pale, became unconscious, and remained so for two or three hours. At the end of that time she was confused, unable to utter any intelligible sentence, clipped her words, made some sounds that were quite inarticulate, and had marked right hemiplegia, the features being drawn to one side, the right arm being completely, the right leg incompletely, paralysed. At the end of three days speech was perfect; and at the end of a fortnight the hemiplegia had disappeared. The most rational interpretation of such case is, that an embolus blocked up the left middle cerebral artery, and led to impaired nutrition of the brain, which equals the first stage of softening; but that, owing to either the re-establishment of the circulation by the breaking up or removal of the embolus, or to the perfect establishment of the circulation in the collateral vessels, the nutrition was restored to its ordinary condition.

Sensibility is sometimes quite destroyed at the time of attack, and for some few minutes afterwards; but in the greater number of cases it is only dulled or impaired, and subsequently changed. While the patient is lying apparently unconscious, or only half conscious, it is often obvious that some sensibility is present, for he moans, moves about uneasily, puts his hand to his head, and starts or draws away some one or another of his limbs, if the skin be scratched or pinched. It is probable that there is headache, and a general feeling of distress, with, very frequently, some distressing sensation in one or more of the limbs. Often before the patient is able to speak, he is evidently uneasy in some of the extremities, and these are usually on one side of the body, and are paralysed; he looks inquiringly at them, or rubs them, moans at them, and cries out if they be either moved or touched. When sufficiently conscious to make himself intelligible, the patient often complains of coldness, or numbness, or "queer feelings" in the arm or leg of one side; of headache, or discomfort in the head not amounting to pain; of a bewildered feeling, and some vertigo. There is said to have been occasionally hyperæsthesia, and that its occurrence
SOFTENING OF THE BRAIN.

in the limbs affected by a stroke of hemiplegia is highly characteristic of acute softening of the brain. It would appear, however, that, instead of true hyperæsthesia, there is a modified sensibility, such as that described above, and that it renders ordinary impressions painful; sometimes these modifications present very curious features, the patient feels distinctly and painfully any impression on the skin, but is unable to refer it to its proper locality. For example, a pinch on the sole of the foot is referred to the inguinal region, while similar irritation above the knee may be felt in the shoulder, or side of the neck; and sometimes the sensation may be referred to the wrong side of the body.

In the majority of cases the sensibility of the limbs is, after an apoplectic attack of softening, speedily restored to its normal condition.

The special senses are, as a rule, unaffected except in the earliest stage of the attack, when all of them may be in abeyance. There is not rarely some complaint of tinnitus, and of musæ, or of dulness in hearing, or mistiness of sight, but there is no one change which is characteristic of softening. There is often to be observed some marked peculiarity in the eyeballs and in the pupils, which being, however, illustrations of altered motility rather than of sensibility, will be described under the following heading.

The symptoms due to changes in motility. It has been often observed that the eyeballs are directed to one side, and that the head is turned in the same direction, so as to give the idea that the patient is making an effort to look at something by the side of him, and usually on the opposite side to that of the paralysis in limbs. If carefully examined it may sometimes be shown that the patient does not see at all, and that the retina is quite insensible to light; while in other cases the patient sees distinctly, and may by an effort of the will bring the eyeballs to the middle line, or even beyond it and to the opposite side. In one curious case, under my care in University College Hospital, this synergic condition of the eyeballs was observed for nearly a fortnight, at the end of which time the patient died. The patient was, when roused, sufficiently sensible to give a coherent account of himself, his sight and hearing were good, he could distinguish not only objects but colours, and seemed rather amused at being put through any examination on such points, yet while talking to me the eyeballs were constantly turned towards the right side, and so much so as to hide a considerable portion of each iris beneath the lids at the left inner, and right outer angles. The patient often fell asleep, and began to snore while the students were standing round his bed, and what was very interesting to observe was this, that at the moment of doing so the eyeballs returned to the middle line. Upon touching him, or speaking to him so as to rouse him a little, the synergic movement again instantly appeared. Owing to the ease with which the transition from sleeping to waking could be effected in this case, the above observation was repeated many dozens of times, and
always with a similar result. The eyeballs are usually, except at or
soon after the occurrence of the attack, unaffected. It is the rare
exception, and not the rule, to meet with strabismus even to a slight
degree. There is nothing characteristic in the condition of the pupils;
they may be found in almost every degree of either dilatation or con-
traction, and they are usually equal on the two sides in cases of acute
softening. Their relation to light is determined by the general
sensorial condition rather than by any special involvement of their
own motor centres. It has been said that occasionally the pupils
dilate upon exposure to light and contract upon its withdrawal, but
there has been, I believe, a fallacy in such observations which it is
very easy to correct. The facts as they have been witnessed by my-
self in many cases are these, that the patient is found asleep, or in a
state of half-unconsciousness with contracted pupils; a strong light is
brought before him, or the eyelids are suddenly raised, and then
immediately there is dilatation; left to himself, again the drowsiness
comes on, and the pupils pass into the state of contraction. The
pupils dilate because the patient is roused, not because they are
exposed to light; the contraction and dilatation that have been
observed have had no relation to light or darkness, but simply to the
facts of sleeping and of waking. This I have shown again and again
by gently raising the lids of such a patient, and exposing the con-
tracted pupils to the light without arousing him; there is then no
dilatation nor change of any kind, but if he be then addressed loudly
by name, or if his toe be pinched so that he is awakened, the pupils
instantly dilate.

The features are sometimes quite symmetrical, both when at rest
and when in motion; but commonly there is some deviation, noticed
most distinctly in the lower part of the face at the angle of the mouth
when the patient speaks or laughs, and sometimes it is so trifling that
it may escape observation unless the patient smiles, or makes a forced
effort to exhibit either the upper or the lower teeth. In other cases
there is marked paralysis of the face on one side, and dragging of the
features towards the other, with deviation of the tongue; but let it be
remembered that this paralysis does not, as a rule to which there are
very few exceptions, involve the muscles of the forehead, eyeballs,
eyelids, or pupils. The patients can equally raise the eyelids, open or
close the eyes, and there is neither ptosis nor strabismus.

The speech is commonly interfered with, not only at the moment of
attack but for a long time afterwards, and sometimes persistently. It
may be so thoroughly abolished that no intelligible sound is uttered,
although it is obvious that ideas of some kind are passing through the
patient's mind; it may, on the other hand, be so slightly affected that
alteration is observed only in the articulation of certain sounds, such
as those of the letters l or r. Between these two extremes there is
almost every variety of degree in the impairment of speech as a
mechanical act, and there is also every shade of difference in the
precision with which it expresses mental processes. Some patients
can read with ease and correctness, articulating every sound distinctly, and yet they cannot construct for themselves a sentence of half a dozen words, so as to answer intelligibly the simplest question. Such patients, although able to hold a pen and to copy sentences, or sometimes to write a few words from dictation, cannot compose anything for themselves. In such instances language is interfered with on its intellectual side. Other patients can write well, when not flurried can talk for a little time so as to be understood, can help to convey their meaning by signs and gestures; but when "excited," or sometimes even when not disturbed in such manner, they can make no such succession of articulate sounds as shall be intelligible. Here speech is interfered with on its mechanical side. In the former group of cases there is usually paralysis on the right side of the body: in the latter there is not any constancy in such association. It is to the former class that the terms "aphasia" and "aphemia" have been applied; and it is not rare to meet with cases which illustrate either it or the opposite condition; it is exceedingly easy to recognise intellectually the difference between the two extremes of symptoms, or between them as conjoint elements in a particular case; but by far the most common event is to meet with such combinations of the two that it is by no means so easy to say how much is due to the one failure and how much to the other.

As the words aphasia and aphemia have now passed into frequent use, and the conditions described by them have become not unfrequently the topics for medico-legal investigation, it is desirable that some further attention should be directed to them, or to what they mean. Aphemia was the word constructed by M. Broca;¹ and aphasia, an old Greek word, signifying the dumbness occasioned by strong emotion, was that used by M. Trousseau² to denote the same thing, viz. the loss of speech or of articulate language, when occurring as the symptom of disease.

The condition now well known as aphasia was observed by the older writers on medicine, some of whom appear to have recognised the distinction, and others to have failed to do so, between it and a more general condition of injury to the nervous centres. But the special pathological significance of the loss of language has been demonstrated within a recent period. Dr. Gall was the first who sought to discover the locality or seat of what he, in accordance with a certain school of philosophy, was led to regard as the separate faculty of language, and he arrived at the conclusion that this faculty had its place in those portions of the anterior lobes of the brain which lie upon the suprâ-orbital plates.

The idea of Dr. Gall was taken up and strongly advocated by M. Bouillaud,³ who distinguished, with care, between the recollection of words and the power of producing distinct sounds for their expression.

¹ Sur le Siège de la Faculté du Langage articulé, Bullet. de la Soc. Anat. 1861.
² Gaz. des Hôpitaux, 1864.
³ Traité de l'Encéphalite.
M. Bouillaud's great point, however, was to show that lesions of the anterior lobes of the brain occasioned loss of the faculty of speech, whereas diseases of other portions of the nervous centres were not so accompanied. Exceptions to Bouillaud's law were somewhat frequently pointed out both in this country and in France, and until a few years ago the general doctrine had almost fallen into complete disregard, although M. Bouillaud had repeatedly brought forward fresh facts in confirmation of his dogma.

The next step of great importance was taken by M. Dax, who, in 1836, pointed out, as the result of his analysis of numerous observations, that disturbances in the faculty of speech were always related to lesions of the left hemisphere, and never to those of the right. This work, to which my attention has been called by the able author of the article on Aphasia, in the new "Dictionnaire Encyclopédique des Sciences Médecinales," was entitled "Lesions de la Moitié gauche de l'Encéphale coïncidant avec l'Oubli des Signes de la Penseé." The paper of M. Dax appears to have attracted little notice, and it was not until nearly thirty years had elapsed, that M. Broca produced his celebrated paper, in which he announced his conclusion that the seat of the faculty of articulate language was in the second, and especially in the third, frontal convolution of the left anterior lobe of the brain. M. Broca used the word aphemia to denote the condition of patients thus affected; M. Trousseau the word aphasia. The last step in this history, and one almost equal in importance to either that had preceded it, was taken by Dr. Hughlings Jackson, who arrived independently at a conclusion similar to that of MM. Dax and Broca, but who went still further than either, and showed the anatomical nature of the lesion which most frequently caused aphasia, viz. plugging of the middle cerebral artery on the left side by an embolus derived from valvular disease of the heart.

Aphasia may be produced by numerous diseases of the brain—such, for example, as congestion, hemorrhage, or tumour, but the most frequent cause is that to which Dr. Jackson directed special attention. Certain aphasic patients can write, while others fail to do so; those who are capable of the act occasionally write sense, frequently nonsense, but more frequently either unintelligible characters, or distinct but unconnected words. Those who cannot write at all are usually, it must be remembered, paralysed on the right side. Certain patients are able to make intelligible signs, others fail to do so; some have the power to calculate, to draw figures, and to perform on musical instruments, while others lose these faculties together with that of articulate language.

The mental state of the patient varies greatly, from a condition of almost perfect intelligence to that of almost complete fatuity. On

1 Gaz. Hebdomad. 28 Avril, 1865.
2 Sur le Siège de la Faculté du Langage articulé, ant. cit.
several occasions the question has been raised whether an individual in a condition of aphasia should be regarded as competent to make a will. No general principle can be laid down with regard to so complicated a question, but each case must be determined on its own merits; still it must be remembered,—1st, That while intelligence may remain intact, the power of expression may be so damaged that it is impossible for any one to be certain that he has correctly interpreted the patient's meaning. 2d, That the patient may be distinctly capable of intellectual decision on matters up to a certain point of complexity, and quite incapable of dealing with those which are beyond that point; that he may be able to decide some simple question, whereas he becomes bewildered when attempting to unravel those which require sustained thought for their comprehension. 3rd, That the facts which are most valuable as bearing on this question are very rare, and contradictory, viz. those which are supplied by patients who have been aphasic, have recovered, have remembered their previous mental condition, and have been able to give an account of it. On the one hand, there has been obvious mental obscurity; on the other, perfect clearness of intelligence; although, as in the case of Lordat, the memory for words was lost as well as the faculty for their expression. 4th, That the balance of evidence is to the effect that the mind is usually somewhat damaged, although its degree of impairment may vary between wide ranges; that the loss of speech in aphasia may co-exist with loss of mental power, but that it does not depend upon it. A patient may be dumb because he has no idea to convey, but such a person is not aphasic; he may have much to say, but be unable to find the words in which to express his thoughts,—such a patient is aphasic; he may be quite clear in his thought, quite certain of his words, and able to write them with facility, but he cannot speak articulately, because he cannot make the sounds he wants,—such patient is not aphasic in the true sense of the word, but is paralysed in either the tongue, lips, or palate, or in all of them together.

The condition of aphasia has its analogues in locomotor ataxy, writer's cramp, and allied affections; and similar physiological considerations will carry the explanation of these curious states to about the same level of precision. Talking, walking, and writing are each of them very complicated processes, and are, in man at least, the result of education. Artificial, as well as natural, associations of nerve-action are involved in each of them, and the result which ought to come from such co-ordination may be stopped at any point. We cannot yet assert what is the primary loss in the condition of ataxy, or in that of writer's cramp, neither can we do so with any accuracy in regard of aphasia. In each of them desire, volition, and intelligence may co-exist with entire muscular capacity: and yet the patient who wishes, tries, and knows how to walk, to talk, or to write;

2 See article Writer's Cramp, p. 290.
and who, moreover, has full power in his legs, his arms, and his apparatus for articulation, is unable to accomplish his purpose: he staggers and falls in the one instance, he makes illegible scrawlings in the second, and meaningless sounds or unintelligible jumbles of words in the last.

The limbs are almost invariably paralysed, when there is softening of the brain, sometimes on both sides of the body, but with far greater frequency on one side. The paralysis is usually not absolute; it is more marked in the upper than in the lower extremity; it is seen to its highest degree in the fingers or toes, to its lowest degree in the shoulder or hip, and with intermediate severity in the forearm and leg. There is commonly some spasmodic contraction of the muscles which are paralysed, and this may take the form of either tonic rigidity, or of occasional clonic, or even choreic movements. Sometimes the muscles are rigid at the very moment of the apoplectic seizure, but more commonly the reverse is observed, there is complete flaccidity, and not until after three or four hours is the stiffness of limb to be recognised. At first it is noticed only after repeated flexion and extension of a joint; subsequently it is persistent, and is not developed but simply exaggerated by attempts at movement. This rigidity is distributed with irregularity, and is noticed principally in the shoulder, elbow, and knee-joints; and in this respect it differs notably from what has been termed "late rigidity," viz. that stiffness of limb which comes on after paralysis has lasted for many weeks or months, and which is distributed like paralysis itself with prevailing frequency in the distal extremities of limbs, and undergoes a gradual diminution as the joints are tested, one by one, from below upwards.

The electric irritability of muscles I have often found to be absolutely normal, even when paralysis is complete, and has remained so for a considerable time; its persistence or the reverse has not been determined by either the degree, duration, or locality of the paralysis, by the presence or absence of rigidity or of wasting. The irritability of the paralysed muscles, as tested by percussion, has been found often in considerable excess, and this when the electric contractility has been normal. Let it be distinctly understood that I am not now speaking of the force of muscular contraction, which is invariably, or almost invariably, diminished in a palsied limb, but of the readiness of response to electricity, which is tested—not by the vehemence of contraction in a muscle, but—by the weakness of the electric power which will bring such muscle into play. In this sense the palsied limb exhibits every condition of irritability, viz. the normal, excess, or diminution. It does not appear to be of any moment in the diagnosis of cerebral softening from any other lesion in the brain, but it is well to bear in mind the facts that have been mentioned, inasmuch as mistakes have sometimes arisen owing to a confusion of terms when the distinction is being made between cerebral and spinal lesion or disease.

1 See Dr. Todd's Clinical Lectures.
There may be no general symptoms in cases of acute softening; at the time of seizure the patient may have been in apparently good health. As already stated, however, this is not common. Usually the individual is "older than his years," as shown by aspect, manner, gait, premature baldness, or greyness of head; he has been weak for some time, has been threatened with a "break-down somewhere," has suffered from disease of heart or kidney; exhibits areus senilis, and has a rigid pulse.¹

Beyond these general states there is nothing to be noted; the patient may, and often does, vomit when the attack is beginning to clear away, and some slight consciousness returns, but it is rare to meet with a repetition of the vomiting. The appetite often is quite good; the digestion, secretions, and evacuations, natural: the temperature, usually quite normal, is sometimes raised to a very high point, and in many cases is notably depressed in the affected limbs. When the temperature has been raised there has been considerable jactitation of the limbs, or convulsive movements, more or less general in their distribution. (See pp. 444 and 446.)

(b) The convulsive form of acute softening of the brain is sometimes so distinct in its features that the case is more likely to be confounded with epilepsy than with hemorrhage or congestive apoplexy. After a few of the premonitory symptoms already described (p. 435) the patient is taken in a fit, which passes through the ordinary phases of an epileptic attack; but the patient does not become profoundly stupid or sleepy afterwards. He is, perhaps, restless, and a little loquacious, or he may be simply quiet, but "not quite himself," for a few minutes, an hour, or even longer, when a second seizure follows, in its turn to be succeeded by a third, and so on; each convulsion being followed by increasing stupor, and almost invariably by paralysis.

Regarded closely, these facts are to be observed with respect to the history of the disease. The premonitory symptoms, although so slight as to have attracted little notice at the time of their occurrence, are found, when attention has been directed to them by the onset of

¹ In an interesting case recently under my care in University College Hospital, a man became suddenly hemiplegic and aphasic, and continued so until he died. There was distinct evidence of old valvular disease of the heart, the radial arteries were hard and visible, the brachial arteries when he bent his elbows stood out like large twisted cords, the pulsation of which was not only excessive and visible, but distinctly locomotive; there was highly-marked areus senilis; the man was old, bald, and grey. The inference drawn from these symptoms was that there was softening in and below the left corpus striatum, and that the softening was due to disease of the cerebral vessels. On post-mortem examination the diagnosis was verified exactly as to the nature and locality of the disease; but, strange to say, the brachial arteries, which were inspected carefully, presented no unhealthy appearance, and exhibited their ordinary amount of elasticity when stretched between the fingers. The inference from this is important, viz.: that vessels may lose their elasticity during life, and that to such a degree as to form valuable guides in the diagnosis of disease, but yet there may be no atheromatous deposit, or other change in their physical appearance which can be detected after death. The mode in which the function is performed during life is a better test of the physical capacity and condition of the organ than is the physical state of the dead artery when examined directly by the hand and by the eye.
convulsions, to have been highly significant of impending evil. They consist generally in some marked change in the mental condition of the patient, such as peculiar drowsiness, listlessness, weariness, impatience, or some flaw in memory, with distinct but momentary incapacity to understand what is said. There may be, however, some little hesitancy in speech, the mispronunciation of a few words, a little weakness of one side, or some vague feeling of malaise, with numbness of extremities, vertigo, or faintness, thought to be either hysterical or dyspeptic in their origin, until the fit occurs and demonstrates the gravity of their meaning. The convulsions, although resembling epileptic convulsions in the main, differ from them in certain particulars, viz.:—The tonic stage is but feebly marked, and there is not much asphyxia. Clonic spasms are more violent on one side of the body than on the other, and they continue for a long time. The patient does not “come out of the fits,” but passes from one into another with no distinct intervening period of quiescence. The fits recur in increasingly rapid succession, and at length the patient can scarcely be said to be either “in the fit” or “out of it.” He lies in a semi-comatose condition, occasionally muttering, and making movements which appear to be voluntary, but which are interrupted by spasmodic jerks, by suspension of the breathing, or by momentary tetanic rigidity. Gradually the limbs on one side cease to exhibit voluntary movement, they fall heavily when allowed to do so; the eyeballs are often directed to one side, and the features lose their symmetry; and thus the case goes on until it passes from a convulsive into an “apoplectic,” or paralytic form. The patient who was “taken in a fit,” thought to be epileptic or dyspeptic, becomes distinctly hemiplegic, and the true nature of the case is recognised.

From this condition there may be partial restoration; after a few days of marked disturbance, intelligence returns up to a point varying through wide ranges, and the state of the patient may be that described in the previous section (see page 436). The convulsions, however, sooner or later, recur; either to be again recovered from, or to carry the patient beyond the reach of hope. The intervals between the attacks of convulsions may be either weeks or months; but in many cases the course is much more rapid, and the patient dies within twenty-four or forty-eight hours from the onset of the fits.

e) The form marked by delirium has usually been preceded by distinct premonitory symptoms, and it is most commonly observed at advanced age. The patient suddenly “wanders” in his talk, becomes loquacious or restless, is busy in manner, exerts himself, seems tired, and falls asleep. He wakes up, somewhat confused, but appears “to be himself again” for a few days, or even weeks, when the confusion and delirium reappear, and are more persistent. There is no complete restoration, but gradually one side is found to be paralysed, or to be slightly weaker than the other. The delirium alternates with coma, more or less profound; and the patient passes into a state like that following either the apoplectic or the convulsive form.
The delirium, usually mild, is sometimes violent; but when it is so there is generally some distinct meningitis, and the case runs a rapid course, reaching its termination in a few days.

3. The final symptoms of softening, like the prodromata, are similar in their character whatever the form in which the attack takes place. The patient becomes more and more comatose, the paralysis extends to the sphincters, the respiration becomes embarrassed, and death follows, usually "without a struggle." Nothing is more gradual or more tranquil than the mode in which the sleep of such patients often deepens, almost imperceptibly, into the sleep of death.

A peculiar form of softening has been described by M. Duparcque, as occurring in children of precocious intelligence, the symptoms of this condition being the following:—headache with drowsiness, perfect integrity of the mind, exaltation of the special senses and of general sensibility, without fever, delirium, or convulsions. After death the only change which has been discovererd has been softening of the brain. M. Duparcque denominates this disease, "Ramollissement blanc aign essentiel chez les enfants." \(^1\)

**CHRONIC SOFTENING OF THE BRAIN.**

The symptoms of this condition may follow an "apoplectic seizure," whether the latter has had for its anatomical basis congestion, haemorrhage, or acute ramollissement. They may, on the other hand, be developed very slowly and insidiously, and may, or may not, be preceded by those phenomena already described as "premonitory" of acute softening.

There is diminution of intelligence. The patient is unable to pay attention, and consequently fails to receive new ideas. Subsequently memory is impaired, past ideas are not recalled with readiness, and there is general confusion and incoherence. Sometimes there is mild delirium, or merely a restless and excited manner, towards the evening of the day, or in the night; occasionally there is the monotonous repetition of a particular word or act, which may continue for hours, days, or even weeks.

In regard of emotion the majority exhibit dulness, or some degree of melancholy; and it is not uncommon to find that the expression of feeling is very little under control. In other cases laughing and crying are very common; but they occur without assignable cause, and without the apparent existence of any correspondent emotion. The intellectual weakness increases, and the patient becomes drowsy. At first he may be aroused, but subsequently there is profound coma, and the patient dies comatose. In rare cases, however, the intellect may be preserved throughout. The gradual failure, one by one, of the intellectual faculties is, \(\text{per se,}\) one of the most characteristic symptoms;

\(^1\) Archives générales de Médecine, Fév. 1852, quoted by M. Valleix, Guide du Mél. prat., tom. 2\(^{me}\), p. 176.
A SYSTEM OF MEDICINE.

and the peculiar monotony (of word or action) has led Durand Fardel to a diagnosis in some obscure cases.

The most common alteration of sensibility is cephalalgia. It exists in about half the cases, and is felt generally among the earlier symptoms; but sometimes does not commence until an advanced period, and it generally disappears towards the close of life. Its intensity is highly variable, rarely so great as that of meningitis, or à fortiori of tumour; its locality is frontal in the majority, and it is not often confined to one side of the head. When pain is not present there is generally a sense of weight and confusion of head; and, as I have observed in many cases, such a peculiar sensation that the patient says he fears his "mind is going." Painful sensations are often present in the limbs; and they are sometimes referred to the surface, sometimes to the muscles, and in other cases to the articulations. These modifications assume the form of so-called hyperesthesie, cutaneous and muscular; or of numbness, formication, &c. They are commonly limited in extent to the parts presenting motorial changes; and when this is the case, they are highly characteristic.

Diminution of sensibility is common, but anaesthesia is rare; and, in respect of the former, it usually exists in conjunction with paralysis. These changes are gradual and imperfect in their development; and it is uncommon to find anaesthesia of the special senses.

Unless an apoplectiform attack has taken place, the muscles rarely exhibit any sudden changes; but when such a seizure has occurred, there may be complete hemiplegia; the face, articulation, the tongue, and the limbs of one side being involved in paralysis.

Paralysis in the typical form of chronic softening is developed gradually; weakness of the muscles preceding their complete removal from volitional control. Hemiplegia is the most common distribution; but there may be general paralysis, incomplete in degree; and this is important as a distinction from the persistent paralysis of hæmorrhage. At first, one leg drags in walking, or one hand feels less strong than the other, and grasps less firmly. The diminution progresses in an intermittent course; paralysis lasting sometimes for a few minutes or hours, and then the power returning. The motorial changes may, however, be limited to particular groups of muscles; for example, those of the face, of speech, of one arm, &c. Spasm, of tonic character, exists with great frequency, and may be found in the paralysed, or non-paralysed side, though much more commonly in the former. The rigidity increases gradually, and persists until within a few days of death, when it usually disappears altogether. Tremors or epileptoid convulsions may alternate with, or take the place of, tonic spasm; or there may be local clonic contractions, and the muscles may be unduly sensitive to percussion. Paralysis generally occurs for some days or hours before death; and then stertor, involuntary micturition, and universal flaccidity are present.
SOFTENING OF THE BRAIN.

Pathology.—Since the year 1820 softening of the brain has received considerable attention from pathologists, and more especially from those of the French school. Previous to this time, it is true, such a pathological condition had been recognised and reported by several observers, and among them by Morgagni, but their accounts are meagre and unimportant, so that for the first description of the disease we have to refer to the works of Lallemand and Rostan. The first of these writers looked upon all softenings of the brain as of an inflammatory nature, and there can be little doubt that many of the cases he described were really instances of Cerebritis of traumatic origin associated with inflammation of the meninges; whilst Rostan, whose observations were made upon people of an advanced age at the Salpêtrière, thought these affections were sometimes inflammatory, and sometimes not. The latter, also, first called attention to the fact of the frequent association of softenings of the brain with calcification of the arteries in old people. Since this time the opinions entertained by different writers as to the nature of softenings of the brain have been various, though for the most part they may be ranged under two principal categories, since the subject which has always been most in dispute (and which cannot now be said to be entirely settled) has been, whether we are to regard these affections as inflammatory or non-inflammatory in their origin. The great, though pardonable error of the earlier pathologists was, that they looked upon softening of the brain as a single substantive disease, instead of regarding it, as we now do, as the pathological sequence of a multiplicity of different conditions. And, as we shall hope to show, much of the difference of opinion amongst later pathologists has been engendered and propagated by their habit of looking at the various kinds of softening of the brain too much from the mere point of view of morbid anatomy, so that some have attached an undue importance to certain appearances, the real nature and value of which could only be rightly estimated by a due consideration of the pathology and mode of origin of the lesions in question.

Before dwelling upon this point further, I will briefly indicate the fluctuations of opinion amongst the principal successive writers on this subject after Lallemand and Rostan.

Cruselhier held that certain forms of softening were of an inflammatory nature, and certain others not, but more allied to softenings of the stomach and intestines. His "ramollissement apoplectique," or "apoplexie capillaire," as he afterwards termed it, answering to some of the forms of red softening, he did not regard as inflammatory, but as allied by insensible gradations to ordinary apoplexy. Bouillaud

1 De Sadibus et Caus. Morb. t. V., Epist. v. ix Ivi.
3 Rech. sur le Ramolliss. du Cerveau, 1820.
at first proclaimed the inflammatory nature of softenings of the brain, though afterwards he acknowledged the difficulty of the question and the desirability of further investigation on the subject. Andrä rejected the inflammatory doctrine. He spoke of obliteration of arteries and poverty of the blood as probable causes, but he regarded the softening as a special alteration of nutrition which might supervene under the influence of the most different conditions. Abercrombie looked upon softening as a species of gangrene, but spoke of two forms, one of which was essentially inflammatory in its origin, whilst the other, principally met with in old people, was due to disease and obstruction of the cerebral arteries. Much the same views were entertained by Carswell and Copland; and others afterwards insisted, as Abercrombie had done, upon the importance of obliteration of the arteries in connexion with softening of the brain. Amongst the earlier of these may be mentioned Bright, Crisp, Pierry, Gely, Gueneau de Mussy, and Bouchut. But almost at the same time there appeared in France two of the most decided advocates of the inflammatory nature of softening of the brain, namely Gluge, who founded his theory upon the supposed nature of certain granular corpuscles or cells, to which we shall have to refer further on, and Durand-Fardel, who still remained of the same opinion in a work published more than ten years later. Those who had already called attention to arterial obstructions as a cause of cerebral softening referred to atheroma and thromboses, or coagulations in the vessels themselves, but Virchow by his first memoir upon embolism opened up a most fruitful and an entirely new field for inquiries into the pathology of softening of the brain, which has attracted the attention of many investigators, and yielded very important results. Amongst others who have contributed to elucidate this aspect of the question, I may mention Kirkes, Fritz, Schutzenberger, Oppolzer, Cohn, Lancereaux, and the experimental investigations of MM. Prevost and Cotard, referring also to the work of Lancereaux for

SOFTENING OF THE BRAIN.

451

further references, and to the recent volumes of the "Transactions of the Pathological Society of London" for numerous cases recorded by English pathologists. In spite of the light thrown upon the pathology of the disease by the recognition of the frequency of embolism of the cerebral arteries, Durand-Fardel, in 1854, again described the various softenings of the brain as inflammatory affections, and a few years later this view received the support of Calmeil. Rokitansky, as the representative of the Vienna school, also pronounced in favour of the inflammatory nature of red softenings, and amongst British pathologists there are many who still look upon various forms of softening of the brain as inflammatory, principally from the fact of the occurrence in the softened tissue of Gluge's granule cells, which are erroneously supposed to be produced only by a process of inflammation. Amongst these—may be mentioned Hughes Bennett, and Aitken. The latest French writers, however, seem almost entirely agreed as to the non-inflammatory nature of the great majority of cerebral softenings, as may be seen by reference to the works of Lancereaux, Laborde, and Proust, and to the memoirs of Bouchard, and MM. Prevost and Cotard.

The acute course run by many softenings of the brain, and the red and swollen appearance of the part after death, appear at first sight to lend support to the doctrine of their inflammatory origin, though we shall have no difficulty in accounting for these phenomena after the recent careful inquiries into the effects of obstruction to the circulation in different parts of the encephalon. It seems impossible now, moreover, to look upon the large granule corpuscles, or so-called 'compound inflammation globules' of Gluge, as products of inflammation only, though it is owing to the constant presence of these in all but the most recent patches of softening, and the diffusion of Gluge's opinion as to their origin, that has kept up the doctrine of the inflammatory nature of cerebral ramollissement. In their most typical form these bodies present themselves as large spherical or somewhat elongated aggregations of minute granules, generally about \(\frac{1}{1000}\)" in diameter, but varying between \(\frac{1}{1000}\" and \(\frac{1}{100}\". They may either be surrounded by a delicate cell-wall, or this may be absent, and occasionally a clear space indicative of a nucleus may be detected in their interior. From the fact that bodies in every way similar have been found by Turck, Bouchard, myself, and others in secondary

10 Loc. cit.

G G 2
atrophic degenerations of the spinal cord, in which there is a simple
process of wasting and not the slightest suspicion of
the existence of an inflammatory process, we have the
strongest support for the opinions of Virchow, Robin
and other histologists, that these bodies result from the
degeneration of pre-existing cells by the accumulation
of fat and protein granules in their interior. They are
produced from the cells of the neuroglia,\(^1\) or con-
nective tissue of the brain, as held by Virchow: thus
accounting for the presence of granule corpuscles in
the white substance (as well as in the grey) where
formerly no cells were thought to exist. When these cells undergo
the fatty and granular degeneration they appear greatly to enlarge in
size, the cell-wall becomes progressively thinner, and at last dis-
appears, and ultimately the spherical aggregation breaks down into a
mass of granular débris. It is thought also, by some, that granule
corpuscles may originate in part by the aggregation of molecules
originally separate, such as are always plentiful in tissue under-
going degeneration; and by others, from the granular and fatty
degeneration of the drops of myeline, set free from the nerve fibres
in softening nerve tissue. We do not ourselves believe, however, in
either of these latter modes of origin.

The extreme vascularity of the brain, and its naturally soft con-
sistence, must be considered, together with its comparatively small
amount of solid ingredients, in order to explain how it is that dimin-
ution in the nutrition of any of its parts, and the degeneration which
is its accompaniment, should lead to such marked alterations in
consistence as are met with in cerebral softenings. This lowering of
nutrition and subsequent degeneration seems adequate to explain
almost all the forms of ramollissement which exist during life.
Theoretically, taking this view as to the nature of softening of the
brain, we should be compelled to admit that it might be brought about
by, (1) an improper state of the nutritive fluid or blood; (2) by a
want of due activity in the elements of the tissues themselves; and,
(3) by an impediment to the proper circulation of the blood. As
matter of fact, concerning the first cause, we can say nothing positive
as to its being capable alone of producing a condition of cerebral
ramollissement; but where the vitality of the tissues is lowered in
anemic and cachectic states of the system, such as we meet with
in patients suffering from cancer, we can easily imagine that poverty
of blood would be a powerful predisposing cause, if other conditions
were present—indeed, independent of the fact, that these very states of
the system also lead to the production of some of those changes in
the vessels, which we shall see are so frequently instrumental in
bringing about softening of the brain. We can say little, also, as
regards the influence of the second cause, though a primary fatty

\(^1\) 'Mycocytes' of Robin.
degeneration of the nerve elements leading to one form of softening, has been described by Dr. Hughes Bennett.\textsuperscript{1} A proper activity of the elements of the tissues themselves, is certainly one essential in healthy nutrition, and to its gradual failure we may perhaps attribute the occurrence of much of the pathological change characteristic of old age. Doubtless, both alterations in quality of blood, and diminished nutritive activity of tissue elements, may be looked upon as accessory causes of no unfrequent occurrence in the production of cerebral softening, especially in old people. But undoubtedly the most frequent causes of softening of the brain, at all ages, are to be looked for under the third head, which includes all the varieties of impediment to the circulation of the blood. These may be classified in the following manner:

\begin{align*}
\text{Morbid conditions of Cerebral vessels} & : \\
\text{Obstructing circulation} & : \\
\text{Arteries} & \vdots \{ \text{Embolism} \\
\text{Thrombosis} \\
\text{Capillaries} & \vdots \{ \text{Embolism} \\
\text{Veins and Sinuses} & \vdots \{ \text{Thrombosis} \\
\text{Diseases of coats of Capillaries and small Arteries} \\
\text{Preventing osmosis and nutritive exudation} & \\
\end{align*}

1. \textit{Obstruction of Arteries.} \textit{a. Embolism}.—The fibrinous masses of which emboli are composed, have their origin for the most part in the left cavities of the heart and the arch of the aorta, though more rarely they may proceed from the pulmonary veins. They may consist of portions of the fibrinous vegetations which are often met with on the mitral or aortic valves, as the result of endocarditis or atheroma, or of portions of the fibrinous depositions which are apt to form on the rough edges of atheromatous and calcareous patches of the arch of the aorta situated anterior to the origin of the cerebral vessels. Whilst at other times they may be detached portions of old clots formed in the left auricle, or even in the left ventricle in cases where there is a retardation of the force of the current either from fatty degeneration or extreme dilatation of the heart. Virchow believes that cerebral emboli may proceed also from clots formed in the pulmonary veins; and it seems possible that small cancerous masses swept away by the pulmonary veins in cases of carcinoma of the lungs, may occasionally go to form cerebral emboli, since in two cases small cancerous fragments have been found in the healthy heart and aorta—one by Lancereaux,\textsuperscript{2} and once by Vidal.\textsuperscript{3}

\textit{b. Thrombosis}.—The various causes of thrombosis have been so well put by MM. Prevost and Cotard,\textsuperscript{4} that I cannot do better than follow their arrangement.

1. Alteration of the walls of the artery, in which their calibre is

\textsuperscript{1} Clinical Lectures. Fourth Ed. p. 355.
\textsuperscript{2} Bulletin de la Soc. Anatomique, 1858.
\textsuperscript{3} Compt. rendu de la Soc. de Biologie, 1861.
\textsuperscript{4} Gaz. Méd. de Paris, Mai 19th, 1866, p. 336.
often much narrowed, and their lining membrane roughened by atheromatous changes, so as directly to favour local coagulation.

2. Retardation of the rapidity of the circulation also tends to produce spontaneous coagulation. This may be brought about by:—

a. Diseases which weaken the force of the heart, such as dilatation without proportionate hypertrophy, and also, more especially, fatty degeneration. b. Narrowing of the calibre of arteries from atheromatous and other degenerations diminish the rapidity of the circulation in these parts, and so predispose to local coagulation, independently of the roughened surface with which it is usually associated. c. The loss of elasticity in the arterial walls, as a result of their degeneration, also assists in bringing about a retardation, since M. Marey has shown that the elasticity of the arterial walls increases the rapidity of the blood current.

3. And lastly, there are certain special states of the blood which seem to predispose towards the formation of arterial and venous thrombosis, even without an actual diseased condition of the vessels themselves. This tendency is most marked in certain cachetic states of the system, and more especially where the cancerous diathesis is well marked. In these cases, however, it must be remarked, that the feebly acting, and, perhaps, degenerated heart, may be almost as instrumental in bringing about the coagulations, as special alterations in the nature of the blood itself.

Almost all the conditions predisposing to thrombosis are met with in many old people, and this harmonizes well with the extreme frequency with which softenings of the brain, not due to emboli, are also met with in the same subjects. All the cerebral arteries may become the seats of degeneration in old age, so that thrombosis may be met with in any of them, and softenings due to this cause may affect the most various regions of the brain. But the middle cerebral arteries are those which seem especially liable to embolic occlusion, and, according to some observers, that on the left side more frequently than its fellow on the right, though there still seems to be some doubt as regards this latter point. Thus, in forty-four cases collected by Lancereaux, the left internal carotid and its branches were occluded fourteen times, and the right twice; the left middle cerebral twelve times, and the right twelve times; arteries of the pia mater, near the left cerebral peduncle, once; and basilar artery and its branches three times. In eighteen cases reported by MM. Prevost and Cotard, the same frequency of occlusion of the middle cerebral arteries was found, though the numbers are higher for the right than the left side. Thus, the right middle cerebral was occluded seven times, and the left three times; the right anterior cerebral twice, and the left twice; the basilar artery once; the right internal carotid twice, and the left once.

It should be mentioned also, that in the experiments of MM. Prevost and Cotard, in which they injected tobacco seeds into the carotid arteries of dogs, it was almost always found that the sylvian arteries were more especially occluded. In the statistics of thirty-two cases reported by Meissner, the situations are found to be somewhat different. Thus, the most frequent seats of obliteration were ascertained to be the termination of the carotids, where the obstruction was met seven times in one, and twice in both arteries; next, in the posterior cerebral artery, where it was met with eight times; then, in the sylvian artery seven times; in the basilar four; in the vertebral once in one artery, and once in both; and in the artery of the corpus callosum twice.

In almost every case where softening of the brain is associated with thrombosis or embolism of the cerebral arteries, it is found that the obliteration exists in one of the branches beyond the circle of Willis; even though obliteration of the parent trunk also exists at some point before it gives off the branches for this anastomosis. Obliteration of the trunk of the carotid alone, is not sufficient, under ordinary circumstances, to produce cerebral softening, as may be seen from a résumé by M. Ehrmann, of cases in which the carotid arteries have been tied, and the operation was followed by cerebral disturbance. The symptoms of cerebral mischief at first set up gradually disappeared when the circulation was re-established by means of the circle of Willis, and where softening did actually occur, this was due either to the extension of a clot upwards, beyond the circle, into one of the cerebral arteries, or as M. Ehrmann suggests, to some unusual distribution of the arteries themselves at the base of the brain, preventing the establishment of a collateral circulation, such as ordinarily takes place.

The seat of the softening also corresponds with the anatomical distribution of the branch occluded, though the two are never coextensive. Usually the brain in the peripheral portions of the vascular department is healthy, owing to this portion of its tissue being nourished by the collateral capillary circulation, whilst the central portions of the vascular region are principally affected: thus, as Lancereaux points out, in cases of obliteration of the sylvian artery, softening of part of the corpus striatum and of the neighbouring white substance is generally observed, whilst the grey matter of the convolutions as well as the walls of the ventricle are often intact. It has been suggested by Durand Fardel that the obliteration of

---

1 Zur Lehre von der Thrombose und Embolie. Schmidt's Jahrbüch, 1861, No. 1, p. 89.
2 On this subject, Dr. Kirkes wrote:—"Although by the arrangement of the vessels composing the circle of Willis ample provision is made against obstruction ensuing in any of the main arterial channels on either side previous to their arrival at the circle, there is comparatively little provision for an obstruction ensuing in any of the main branches, into which this arterial circle breaks up. This remark applies chiefly to the middle cerebral artery, which, if plugged at its origin, becomes at once altogether useless as a blood-vessel, for nearly all its divisions, especially those for the central parts of the brain, proceed to their several destinations without receiving any anastomosing branch from the other divisions of the circle of Willis."—Med.-Chir. Trans. 1852.
3 Thèses de Strasbourg, 1859.
the arteries is secondary to the softening, and not the cause of it; but, in reply to this, it is only necessary to state that the actual seat of arterial occlusion is almost always outside the softened tissue, and in these cases, as well as in those in which there is obliteration of the arteries within the softened patch itself, an examination of them will either show their walls degenerated and roughened with the formation of a clot in their interior, or else it will establish the existence of a small obstructing mass, differing from recent fibrine in composition and appearance, and unattached to the walls of the vessels.

2. Obstruction of Capillaries.—In certain cases, by the rupture of old clots of the heart having softened centres, or the inner coat of the aorta over large softened atheromatous patches, a mass of granular débris is carried into the cerebral arteries, whilst from the minute size of the particles of which it is composed, these penetrate to and block up the minute arteries and capillaries of the part. If the quantity of matter thus carried to the brain be considerable and widely dispersed, death may rapidly follow before there is time for definite alterations of the cerebral tissue to take place, and owing to the extent of the capillary obliteration the brain may present an anaemic appearance. Such was frequently found to be the case by MM. Prevost and Cotard, when they injected the fine lycopodium powder into the carotid arteries of dogs. When a smaller number of capillaries are obliterated, either by atheromatous matter, small particles of fibrine, or pigment granules,¹ local patches of softening are produced, having the usual characters of softening of the brain due to arterial obstruction.

3. Obstruction of the Veins and Sinuses.—The general causes favourable to the production of thrombosis have already been mentioned. The cases of obliteration of the cerebral veins and sinuses are in part due to these, though, just as frequently, they are the sequences of blows on the head, or inflammatory conditions of the scalp and cranial bones. Indeed, out of the seventy-four instances of thrombosis in the cerebral sinuses which have been recorded by Lancereaux,² and other observers, such as Tonnellé,³ Rillett and Barthez,⁴ Lebert,⁵ Gerhard,⁶ and Von Dusch,⁷ thirty-nine are found to belong to this latter category. And amongst these, in thirty cases there was caries of the bones of the skull: in twenty-four of which it was the temporal bone that was affected as a result of internal otitis. Both the lateral sinuses are seldom implicated in these secondary thromboses, and the longitudinal even more rarely; whereas in those cases in which the thrombosis proceeds from more general causes, such as alterations in the quality of the blood, or slowness of circulation, its almost habitual seat is found to be the superior longitudinal sinus from which the thrombus frequently prolongs itself down to the torcular herophili and on each

³ Journ. Hebde. de Méd. 1829, p. 337.  
⁴ Malad. des Enfants, t. i. p. 161. 1853.  
⁵ Deutsche Klinik, 1857, No. 45.  
SOFTENING OF THE BRAIN.

side into the lateral sinus. It is in this latter class of cases, moreover, that cerebral softenings are associated with the thrombosis. These are of a peculiar kind, consisting principally of a number of small patches of red softening, occupying chiefly the grey matter near the upper surface of the brain, and are often distributed symmetrically over both hemispheres. Occasionally, softening of a portion of brain of considerable extent has been noted. Besides such peculiarities in the seat and distribution of the softened patches, we usually meet, in these cases, with serous effusion into the ventricles and beneath the arachnoid, or more rarely with an actual effusion of blood in these situations, or even in the substance of the brain itself; together with minute patches of haemorrhage in the grey matter, such as have been described by Cruvelhier under the name of "apoplexie capillaire." The actual combination of these conditions met with in individual cases depends upon the seat of the obstruction, the rapidity with which it is brought about, and the condition of the vessels according to the age of the individual. In the secondary thrombosis, on the other hand, there is often evidence of more or less circumscribed inflammation of the meninges, although the cerebral softenings and extravasations of blood very rarely occur. This, according to Von Dusch, is owing to the fact that in these cases the thrombosis starts from the veins in communication with the inflamed spot, and reaches the sinus only after the collateral circulation has had time to establish itself, instead of forming at once in the sinus, and before a collateral circulation has been set up.

4. Alterations in the walls of the Capillaries.—Fatty degeneration of the walls of the capillaries has been described by Hughes Bennett, Paget, Todd, Moosherr, and Charles Robin. This alteration is most frequent in old age, and especially in individuals suffering from Bright's disease, or maladies producing a low chachectic state of the system, when such changes may supervene at a much earlier period than is usual. It is a frequent cause of cerebral haemorrhage, and may also lead to softening when this change is universal and well marked in the capillaries of a certain area. Such a degeneration of the walls of the capillaries must not however be confounded with the accumulation of fat granules and of granule corpuscles on the walls of those capillaries situated in the midst of softened brain substance. The first may be a cause of softening, but the second condition is always a consequence of it. The observations of Moosherr and Robin more particularly have shown that a certain number of fat particles may almost invariably be found within the sheaths of the small arteries and capillaries of the brain when this is quite healthy,

3 Clinical Lectures on Paralysis, &c. 1854.
6 Wedl, Patholog. Histol. (Syd. Soc.) p. 291, fig. 64.
and that, too, even in children. In many cases it is extremely difficult to discriminate between small fat particles and calcareous granules in the walls of the capillaries, without submitting them to the action of dilute hydrochloric acid. This calcareous degeneration of the capillaries is more rare than the ordinary fatty degeneration, though when it exists in an extreme degree, it is also capable of giving rise to softening of the brain, as may be seen by the perusal of a remarkable case reported by M. Delacour, in which the small arteries and capillaries were completely calcified. In these cases, as well as in those of fatty degeneration, the softening is brought about by a gradual diminution in the nutrition of a portion of brain, the capillaries of which have been altered in structure so as no longer to permit the osmosis of a quantity of blood plasma, sufficient to maintain the ordinary balance of nutrition in the surrounding tissue, and to prevent it from undergoing processes of degeneration.

In addition to the various softenings of the brain, which may be produced by the influence of the conditions mentioned, and those of traumatic origin, which are mostly red, from effusion and dissemination of blood, there are also certain secondary or consecutive forms of softening, which may be classified under two heads, viz.:—1. Softenings set up around tumours and adventitious products generally, in the brain. 2. Atrophic softening due to the separation of nerve-fibres from their ganglionic communications. The first variety of secondary softenings will be referred to elsewhere (Art. ADVENTITIOUS PRODUCTS), whilst those under the second head are by no means frequent, the lesion resulting from the separation of a tract of nerve-fibres from their central ganglionic connexions, being usually a simple atrophy or slow wasting, in which, although the method of degeneration has been proved to be identical in the two cases, cerebral softening does not usually occur, apparently owing to the greater slowness with which the atrophic change is brought about. Still softenings from this cause have been met with. This change was pointed out by Cruvelhier in the cerebral peduncles, the pons, and the medulla oblongata, and since his time our knowledge of the process has been greatly advanced by the investigations of Tureck, Waller, Van der Kolk, Phillipex and Vulpian, Gubler, and Bouchard. Laborde has, moreover, quite recently drawn attention to the fact that in cases where there is softening of the corpus striatum or optic thalamus, a similar process is also set up on the surface of the hemispheres in the superficial grey

3 Anat. Patholog.
7 Mém. de la Soc. de Biolog. 1859, p. 343.
8 Archiv. Gén. de Méd. 1859, p. 31.
matter of the convolutions. The softenings of the convolutional grey matter are always on the same side of the brain as the lesions in the central ganglia, and Laborde has also ascertained that a relationship exists between the particular convolutions affected and the particular portions of the central ganglia which have been destroyed, so that where softening of the anterior portion of the corpus striatum or optic thalamus exists, the same process occurs on some portion of the anterior convolutions; with destruction of the central portions, the middle convolutions are affected; and with destructions of the posterior portions of either of the central ganglia, a corresponding change is set up in some of the posterior convolutions. Should future observations confirm the opinions of Laborde, these changes would seem to be related to the secondary atrophic degenerations, and would be most interesting in a physiological as well as a pathological point of view: it is well to mention, however, that M.M. Vulpian and Charcot maintain that the coexistence of these peripheral and central lesions are mere coincidences, and that there is no necessary association between them.

Seat of Cerebral Softening.—Centres of softening may be found in all parts of the brain, but they exist most frequently in the convolutions and most rarely in the cerebellum and pons varolii. Durand Fardel\(^2\) found, as the result of an analysis of his own observations combined with those of Rostan, Andral, Raikem and Lallemand—yielding altogether eighty-six cases of "acute" softening—that the convolutions were affected fifty-nine times, the corpus striatum and optic thalamus, either singly or combined, twenty-eight times, and the white substance of the hemispheres, alone, only nine times. Although the combined statistics yield this result, however, it does not agree with the experience of Rostan\(^3\) alone, who says expressly that the corpora striata and the optic thalami are the parts most frequently affected with softening, and after them the central white substance of the hemispheres. Laborde says\(^4\) that the corpus striatum is affected nearly twice as frequently as the optic thalamus, since he has found the former softened forty-six times and the latter only twenty-four times. He states also, that the change most frequently exists only on one side, though he says it is rare for the two corpora striata to be affected at the same time without a corresponding change in one or other of the optic thalami. The two hemispheres are about equally liable to undergo this change, though as before indicated the softenings of embolic origin seem to occur rather more frequently in the left hemisphere.

The extent of the softened patch is extremely variable, since it may be found from the size of a pea upwards to such an extent that the whole of one lobe, or the greater part of one hemisphere even, may be so changed.

2 Malad. des Vieillards, Paris, 1854, p. 68.
4 Loc. cit. p. 72.
Periods of Life at which Softening of the Brain is most frequent.—Durand Fardel has attempted to show by a combination of his own cases with those of Rostan, Lallemand, Bouillaud and Andral, that softening of the brain may be met with at all periods of life, and is by no means a malady peculiar to old age. Laborde, however, has subjected the same statistics to a more rigid scrutiny, and by eliminating various cases of inflammatory softening of traumatic origin, and others which have been improperly included from various causes, he has found that the very statistics made use of by Durand Fardel do show, if properly sifted, the most undoubted relationship existing between non-inflammatory softening of the brain and old age, since in eighty-one such cases, seventy-five of the individuals were from sixty to seventy-five years of age, four from fifty to sixty, and only two individuals between thirty and fifty years of age. It must not, however, be supposed that softening of the brain is so exclusively a disease of old age as these figures would represent, since softenings of embolic origin are now known frequently to occur in young adults and even in children; softenings from thrombosis, also, may and do occur not uncommonly in adults of all ages suffering from cachectic diseases. Still degeneration of the cerebral arteries and the various causes of thrombosis increase in frequency with increasing age, and so also is it with non-inflammatory softenings of the brain, with which, as we have seen, these conditions have such a close pathological relationship.

Morbid Anatomy.—Softenings of the brain present themselves under different forms according to variations in seat, age, and other conditions, and the common character of diminished consistence which first attracted the attention of pathologists is curiously enough the one least indicative of a morbid change that has taken place during life, since marked alterations of this kind may be induced post mortem. The tests employed by earlier pathologists, therefore, which were intended to establish this one fact of diminished consistence, namely, the effect of a gentle stream of water in washing away the softened tissue, the impressions derived from the sense of touch, and the speedy rounding of the angles which takes place in a portion of brain cut out from the softened portion, are useless for the purpose of demonstrating that we have to do with a pathological process established during life. To make sure of this we must take into account other characters afforded by the softened tissue, and have recourse to more delicate means of investigation, such as are afforded by the microscope and the specific gravity apparatus.

The most notable differences of appearance in softenings of the brain are due to variations in colour, and the greatest variety of tints may be met with. In some cases the softened tissue has a dead white colour, or it may be of a reddish hue, and present all shades from a uniform pinkish tint, through different grades of red, up to a claret colour; whilst in others, various shades of yellow and even brown

1 Loc. cit. pp. 144—185.
discoloration are met with. These colours may exist alone or variously intermixed. But in spite of this apparent complexity, there are three principal kinds of softening, known as the white, the red, and the yellow, under which heads it will be convenient for us to describe the various forms of softening of the brain. And in making this division we do not necessarily look upon these varieties as different stages of the same condition as has been done by Durand-Fardel\(^1\) and Lancereaux\(^2\)—both of whom describe "ramollissement blanc" as the last or chronic condition of red softening. Lallemand also looked upon white softening as due to a purulent infiltration, though the absence of pus has been established again and again by later observers. On the other hand MM. Hardy and Béhier,\(^3\) as well as Rostan and Abercrombie, have pointed out that this kind of softening is often met with in old people, and more particularly in those who are weakened and feeble, which agrees well also with the observations of M. Charcot who has often met with white softening in old people afflicted with cancer at the Salpêtrière.\(^4\) MM. Prevost and Cotard, moreover, admit the existence of a softening of the brain, white from the first, and this has also seemed to be the case in several instances which have fallen under our notice. It would appear probable that white softening is mostly due to a rather more chronic process than that which gives rise to the red, and such as would exist were this change brought about by disease of the coats of the capillaries, and general mal-nutrition from poverty of blood. Prevost and Cotard\(^5\) suggest, also, that in some of those cases, where the softening seems to be associated with obliteration of the vessels, the absence of redness may be due to the extent and nature of the arterial obliteration being such as to prevent the collateral fluxion of blood into the vessels of the diseased part. In other cases they admit that the cause seems inexplicable. Red softening seems to be more particularly limited to cases in which there is arterial obstruction, or impediment on the venous side of the circulation; whilst there can be little doubt that many of the shades of yellow in softenings, are due to alterations which have taken place in what was previously red softening, although Rokitansky has described a special kind of yellow softening having intrinsic characters of its own.

1. White Softening.—In this species of ramollissement, which occurs only in the white substance of the hemispheres, a varying amount of diminution of consistence is met with, without alteration of colour. In some cases the amount of softening is so slight as to escape detection by the unaided senses, whilst in others the portion of brain is reduced to a thin diffused pulp, which may be poured out so as to leave a distinct cavity with irregular though softened walls—for the degeneration is never strictly limited, but shades off imperceptibly into the healthy tissue. Thus, in what appear to be minute circumscribed patches of white softening, granular corpuscles are diffused for some

\(^1\) Malad. des Vieillards, Paris, 1854, p. 72.  
\(^2\) Loc. cit. p. 20.  
\(^3\) Traité de Pathol. int., Paris.  
\(^4\) Vide Proust. Loc. cit. p. 49.  
\(^5\) Gaz. Méd. de Paris, 1866, p. 207.
distance in the firmer tissue surrounding the softened patch. Sometimes nearly the whole of the white substance of one hemisphere may be found in a more or less softened condition. The specific gravity of softened white matter usually falls to 1.032, but when in its natural condition it is about 1.040; and as a general rule it may be said that any portion of the brain when softened has a specific gravity lower by six to eight degrees of the hydrometer scale than the specific gravity of the same part when in its normal condition.1

2. Red Softening.—This variety may be met with either in the grey matter or in the white substance of the brain, though in the former the colouration is generally more distinct and of a darker hue, on account of its naturally greater vascularity. When affecting the grey matter, the patches may be small and distinctly circumscribed, so as to present the appearance of superficial ulcerations, or they may be more diffuse and extensive, presenting less of the appearance of ulcerations, but existing as dark, somewhat swollen patches, which, from their colour, were formerly spoken of as "plagues ecchymotiques," and "taches scorbutiques des convolutions." These have also been described by Cruvelhier2 under the name of "ramollissement hortensia ou lilas." This softening of the convolutional grey matter may exist alone, or be associated with a similar change in the subjacent white matter, or, as Laborde has pointed out, it may coexist with softening of one of the central ganglia on the same side. In these latter cases the softening is often slight, and takes place without much alteration in the natural colour of the part, so that it is liable to be overlooked. Where the convolutions are softened, the grey matter is frequently torn in attempting to strip off the membranes. This may be due, however, to the mere fact of diminished consistence, rather than to any increase in the natural adhesions existing between the parts. Red softening of the white matter often exhibits a general rosy hue intermixed with darker coloured patches from effused blood and minute points of redness, or, as it has been termed, "capillary apoplexy." It may be diversified also with simple white softening here and there, and after a certain time shades of buff, yellow, and even brown colouration supplant or become mixed up with the red. The brown colour is most frequently met with in old patches of softening in the corpus striatum. The red colour being due to the increased quantity of blood in the part, and the extreme congestion of the vessels (combined with staining from transudation of colouring matter), we have in this fact an explanation of the circumstance that when a recent red softening is cut into, the surface often rises up above the level of surrounding parts, and presents a slightly swollen appearance. Also, when red softening of the white matter exists, combined with the same condition of several of the contiguous convolutions, owing to

2 Anat. Patholog. vol. i. Livraison.
the swelling and consequent pressure thus produced, these become flattened on the surface, whilst the sulci are rendered indistinct. The process of degeneration is the same in this form as in the simple white softening, and it may advance to the same condition of diffluence, the colour and composition only of the softened part being altered by the great admixture of blood and the products of its retrograde metamorphosis.

Red softening, if not of traumatic origin, as before stated, is almost invariably connected with obliteration of the vessels or other impediment to the circulation, and the redness and swelling which were formerly considered so indicative of its inflammatory origin, are capable of receiving an explanation, showing them to be dependent upon mechanical rather than vital influences.

It has been known for some time through the writings of Rokitansky and Cohn,¹ that infarctus of the abdominal viscera from arterial obstruction commences as a deep red spot in the territory of the affected artery, owing to the engorged condition of its capillaries and the occurrence of minute extravasations of blood; and quite recently MM. Prevost and Cotard injected into the arterial system of a dog, whose abdominal walls had been opened so as to expose its contained viscera, some water holding tobacco-seeds in suspension. A few moments after the injection, there appeared, at the inferior extremity of the spleen, a red prominent spot of definite outline, which rapidly increased till it equalled that of a two-franc piece. The corresponding branch of the splenic artery was found to be obliterated by the seeds. Ecchymotic looking spots were produced upon the kidneys at the same time. What was here actually seen to take place, accords perfectly with what is observed in cerebral softenings brought about by the injection of foreign bodies into the arterial system, since this constantly results in the production of red softenings with great fullness of the vessels, as has been abundantly proved by the experiments of Cohn, Vulpian, and MM. Prevost and Cotard. Here then, are the two appearances, redness and swelling, produced so rapidly as to make it quite out of the question for us to regard them as of inflammatory origin, in spite of the opinion of Oppolzer, so that we must seek for a mechanical cause of the phenomena. Cohn and Rokitansky attribute the results to a collateral fluxion through the contiguous capillaries, whilst Virchow regards them as the effects of a venous reflux, in consequence of the suppression of the vis à tergo on the side of the artery. In support of the former view, Weber² has since pointed out that when an artery is obliterated, the pressure at the point of obliteration increases, and becomes equal to that at the origin of the artery, and that when a certain number of capillaries are obliterated, the pressure augments in the artery belonging to them, and in those remaining pervious. Prevost and Cotard also support this view, and call attention to the theorem of hydrodynamics upon which it

depends, to the effect, that when a tube receives at one of its extremities a fluid at a certain pressure, and allows it to escape freely at the other extremity, the pressure diminishes from one end to the other of the tube according to an arithmetical progression. Marey\(^1\) has shown that this theorem is applicable to the circulation of blood, owing to the resistance in the veins being so slight as practically to make it appear as though there were a free flow into the capillaries.\(^2\) This increased tension of blood in the collateral capillaries would, therefore, seem to account in great part, not only for the surrounding congestion but for the flux of blood into the territory of the obliterated artery, where it would stagnate; and owing to its increased tension (combined with the progressive weakening of the capillary walls, and the diminution of their usual support from the softening of the surrounding brain tissue), there might easily be conceived to arise the effusions of blood and those dilatations of capillaries such as are actually encountered.

2. Yellow Softening.—A special form of degeneration of brain substance has been described under this head by Rokitansky.\(^3\) It usually occurs in sharply circumscribed spots—varying in size, but rarely exceeding that of a hen’s egg—in which the cerebral substance is converted into a very moist, tremulous, and occasionally gelatinous pulp (retaining none of the characters of proper brain tissue) which rises considerably above the level of the section, and is of a straw or sulphur-yellow colour. In slighter degrees of the disease, the colour is merely dull white, inclining to yellow, though the tissue is much softer and moister than usual. The expressed fluid has a distinctly acid reaction. The transition to the healthy brain tissue is usually abrupt, and there are no signs of inflammation in or around the softened patch. Its usual seat is the white matter of the hemispheres, though it may affect the central ganglia, and much more rarely the convolutional grey matter is implicated. With regard to the pathogeny of this form of softening we are almost entirely in ignorance. Rokitansky looks upon it as a peculiar chemico-pathological transformation of brain substance, in which “the liberation of an acid—the phosphoric, and especially one or more of the fatty acids—may be conjectured to be one of the most important phenomena.” Besides occurring as an independent condition such as above described, this form of yellow cerebral softening is said by Rokitansky to exist frequently around old clots, tumours, or other adventitious products in the brain. Cruvellier\(^4\) has also frequently met with it around old adventitious products, though he has never seen it existing alone.

Besides this special form of yellow softening, as before stated, we meet with this colour in the secondary stage of red softening,

---

2 This is an important point, because Poiseuille (Recher. sur les Causes du Mouv. du Sang.) maintained that the pressure was the same in all parts of the arterial system.
4 Anat. Path. vol. i. Livraison viii*.
where the tint may be partly due to the presence of altered blood pigment, and partly, according to Lancereaux and Virchow, to the presence of what were the red globules of the blood, but which have now been deprived of their haematin.

Histological Alterations and Microscopical Appearances in different Stages.—The changes which take place in the nerve elements of a part, whether from the separation of these from their proper ganglionic connexions, or from the cutting off of the supply of blood to the part, have been shown to be absolutely identical in nature, and to differ only as regards the rapidity with which the change is brought about. This has been proved by the experiments and observations of Phillippeaux and Vulpian on the changes taking place in the peripheral extremities of divided nerves, and by the observations of Turek, Gubler, and Bouchard on the progress of secondary degenerations of the spinal cord, as compared with the ordinary histological changes which take place in softening nerve substance. In the one case we have a simple destruction, or necrobiosis, taking place amongst the elements of the tissue, in which, from the comparatively slow way that they are brought about, all the steps of the process may be easily traced, whilst in the other we have a more rapid and tumultuous form of necrobiosis, which, on account of its rapidity, is associated with diminished consistence. The investigations of MM. Phillippeaux and Vulpian ¹ have yielded the following results. At the end of the first day there is found to be a diminution of the proper excitability in the peripheral extremity of the cut nerve, whilst this is lost altogether at the end of the fourth, and the filaments which had previously shown no change begin to alter in appearance. From the fifth day the medullary substance of the tubes seems to be coagulated, and at the same time fissures establish themselves in its thickness and divide it into unequal blocks or divisions. This is called the segmentation of the nerve tubes. Soon after this the fragments of the medullary substance undergo a further alteration, fatty granules ² form in their interior, which go on increasing, and at last entirely replace the fragments of myeline. Bouchard ³ has recognised precisely the same changes in cases of secondary atrophic degeneration, and speaking of one of these cases he says:—"Independently of the fatty granules contained in the altered tubes, a great number were free between the tissue elements, and at certain points aggregated together into masses, so as to constitute what are known as the 'corps granuleux' of Gluge."

In the same case the vessels presented on their surface heaps of

---

¹ Mém. de la Soc. de Biologie, 1859, p. 343.
² At the end of a certain time the fatty granules are absorbed, and nothing is left but the sheath of Schwann folded on itself and on the axis cylinder. Little is known as to the actual condition of this last, though the researches of Schiff and MM. Phillippeaux and Vulpian go to prove that the return of function in a divided nerve proceeds not from the production of new tubes amongst the débris of the old as formerly supposed, but from the reformation of myeline within the wasted sheaths themselves, and around the axis cylinder which persists for a long time without undergoing much appreciable alteration.
³ Arch. Gén. de Méd. 1866, p. 281.
molecular fat particles, or even a complete envelope of these so as to render the vessels black and opaque under the microscope. Here, then, are produced, without the intervention of inflammation, all the appearances which have been supposed to be characteristic of inflammatory softening of the brain. Dr. Hughes Bennett says:—"Exudative or inflammatory softening always contains granules and granule cells, which are numerous, according to the degree of softening. The granules are for the most part seen coating the vessels, and the cells also may occasionally be seen there in various stages of development. In the demonstrations that are made under the microscope, they are frequently seen diffused among the tubes, which, according to the severity and extent of the lesion, are easily separated from one another, or broken up in a variety of ways."

MM. Prevost and Cotard have found from their experiments on dogs, that at the end of the first twenty-four hours after the obstruction of an artery, there was red pulpy softening, with slight diminution of consistence, and, on examination with the microscope, there were seen broken-up fragments of nerve tubes, drops of myeline, blood corpuscles, and peculiarities of the capillaries, but no granules or granular corpuscles yet. As early as the third day, however, they have found granule corpuscles formed, and an abundance of granular matter scattered about and collected along the walls of the vessels. This last fact is quite in accordance with our own observations, since we lately met with an instance of traumatic softening in which a few fully developed granule corpuscles, and very many in a less mature state, were seen, which must have been produced in rather less than two and a half days. Bouchard believes that these granule corpuscles may result from the "granulo-graisseuse" degeneration of drops of myeline, and Prevost and Cotard also think they may result from the aggregation of granules originally separate. We have, ourselves, never been able to substantiate either of these modes of origin, and we agree with Virchow, in the opinion that they originate from the fatty degeneration of the cells of the neuroglia, since granule corpuscles are commonly met with in the midst of the white matter of the hemispheres, having a more or less distinct cell wall, and showing a large nucleus in their interior, after staining with carmine. The cells of the neuroglia are the only elements existing in this situation capable of giving rise to such bodies. They are also to be seen in

1 Clinical Lectures. Fourth Ed. 1865, p. 354.
2 The man on whom this observation was made fell down an area and fractured his skull. He was admitted into St. Mary's Hospital on Sept. 7, 1866, at 4 p.m., immediately after the accident, and died on the 10th of the same month at 3.10 A.M. The exact interval was, therefore, 2 days, 11 hours, 10 min.
5 Corpuscles almost precisely similar are met with in other organs, whose tissues are in a state of degeneration, which undoubtedly originate from the fatty and granular degeneration of pre-existing cells.
the grey matter lying between the ganglion cells, which, in old age, undergo more or less of the pigmentary degeneration, and present quite a different appearance. Robin formerly held that they were produced by the degeneration of pus cells; but pus cells in their natural state are never met with in simple softening of the brain, and it seems scarcely fair or reasonable to assume that they should be seen only in a state of degeneration. In cases of softening of the convolutional grey matter or central ganglia, a degeneration of the proper nerve cells takes place, and they become filled with dark coloured granules. These are generally at once distinguishable from ordinary granule corpuscles by their irregular, angular shape, and the presence of the stumps of one or more cell prolongations. At the same time that these bodies are forming in the degenerating tissue, granules collect along the walls of the capillaries, partly in an altogether irregular manner, and partly in the form of special masses. Some of the capillaries become completely covered in this way, but the collection is on the walls of the capillaries, and is a consequence, not a cause of the softening. It must not be confounded with fatty degeneration of these vessels, in which the granules are imbedded in the walls of the capillaries. There are other alterations of the capillaries met with more particularly in red softening, from the earliest stages, which have been particularly dwelt upon by Laborde.\footnote{Loc. cit. p. 114.}

At first, partial dilatations of the walls of the capillaries are seen, like minute aneurysmal swellings, and in other places little ampuliform dilatations, including the whole circumference of the vessel, and constituting what he describes as the moniliform condition of the capillaries. At a later stage, complete as well as partial dilatations of the capillaries are met with, and actual ruptures here and there, with minute extravasations of blood, whilst the surrounding nerve elements are just beginning to break up. Still later, the capillaries become enormously dilated, and their walls thin and granular from degeneration. The punctiform hæmorrhage, to which Cruvelhier gave the name of "apoplexie capillaire," is sometimes due to minute extravasations from rupture of the capillaries, sometimes to the extreme dilatation of capillaries gorged with blood, and often to the production of what has been wrongly called a dissecting aneurysm, occasioned by rupture of the proper wall of the capillary, and effusion of blood into the lymphatic sheath which surrounds it. The blood remaining in the capillaries, and also that effused externally amongst the nerve elements, may, for a certain time, show traces of the blood corpuscles, more or less decolorized and yellow, as well as flattened and pressed together; whilst mixed up with them are reddish or reddish yellow flakes of tissue, stained by the transuded hæmatine. In the minute patches of extravasated blood, where the colouring matter exists in some quantity, we afterwards find it in the form of amorphous, yellow or orange-coloured granules or flakes, intermixed with the characteristic orange or ruby-coloured
crystals of hematoïdine. These are very minute, and of an oblique rhombic prismatic form. It is not known exactly how long they take to form in extravasations of blood in the human brain. Dr. Wilks has, however, met with them as soon as three weeks after such an occurrence, and Cruvelhier found the "coloration jaune orange," developed after twenty-five days in the seat of an hemorrhagic effusion into the brain. Once formed, according to Virchow, the hematoïdine crystals remain as indelible evidences of past extravasation of blood.

In the extreme stage of softening, the fluid matter occupying its site no longer presents the slightest trace of nerve structure—the degeneration is complete, and nothing can be recognised by the microscope save granules and granule cells, mixed up with the various kinds of blood pigments, amorphous fragments of tissue, and the débris of degenerated vessels. When we meet with the last stage of red softening, and especially when this is situated in the corpus striatum, or optic thalamus, the contents of the softened centre may present a brownish or even chocolate hue.

The fatty degeneration being complete, the process of repair begins in a variable time, but probably from one to two months after the commencement of the degeneration. These alterations have been fully described by Durand-Fardel, and differ according as they are situated at the surface of the brain, or in its central parts. In the former situation the process results in the formation of the so-called "plaques jaunes," and in the latter it is accomplished by what Durand-Fardel calls "infiltration celluleuse."

The so-called "plaques jaunes" have been well represented by Cruvelhier, and fully described by Durand-Fardel. They exist in the form of yellow or ochre-coloured, rounded patches, which may be confined to a single convolution, or may extend over several, and at the same time dip down into the sulci. The pia-mater over them may sometimes be easily stripped off, and at other times it is adherent. The tissue of the patch, though pliable, is tough and resistant to the knife; it usually implicates the cortical substance only, and at the circumference is sharply defined from the surrounding healthy tissue. More rarely, however, it is separated, as well circumferentially as beneath, from the healthy brain substance, by a layer of softened tissue. Histologically, these patches are made of connective-tissue containing an abundance of nuclei and also intermingled hematoïdine granules and crystals of hematoïdine, together with fatty particles, a few granule corpuscles, and degenerated vessels. Rokitansky denies that these yellow patches are the sequelæ of softening of the convolutions, and looks upon them as the traces of superficial hemorrhage. But a recent experiment by Prevost and Cotard goes

1 Lect. on Path. Anat. 1859, p. 133.
3 Anat. Path. Livraison 33, pl. 2.
SOFTENING OF THE BRAIN.

strongly to support the view of Durand-Fardel. They found a well-marked yellow patch, on the middle lobe of one of the hemispheres of a dog, which was in every way similar to those met with in man: and the corresponding middle cerebral artery of the dog had been obliterated, thirty-five days previous to the death of the animal, by the injection of tobacco seeds into the carotid artery. From what we ourselves have seen, however, we are inclined to think that superficial extravasations of blood into the pia-mater may also, as Rokitansky says, give rise to yellow patches, though of a different kind from the "plaques jaunes" described by Durand-Fardel. In such the coloration is almost entirely due to an accumulation of blood pigment in the meshes of the pia-mater, with atrophy of the subjacent convolution, rather than to a fibro-cellular conversion of the substance of the grey matter itself.

When a focus of softening in the centre of the hemispheres begins to undergo the process of repair, the walls of the softened cavity become bounded by a pulpy tissue of a white or greyish colour, which is imperceptibly continuous with the neuroglia of the healthy nerve substance. Tissue of the same kind also extends across the cavity in different directions, breaking it up into divisions or compartments, in the meshes of which may be found a whitish liquid containing fragments of old tissue which have not yet completely undergone the fatty metamorphosis. This fluid holds in suspension, also, fat particles, and a number of corpora amyloeae. The formation of this connective tissue, containing vessels, constitutes the "infiltration celluleuse" of Durand-Fardel. Though met with principally in the white substance of the hemispheres, it is also seen more rarely in the central ganglia. When situated in the corpora striata, the walls, instead of being white, are often of a yellowish or ochre colour, which makes the identity of this process with that which gives rise to the "plaques jaunes" of the convolutions all the more evident. The fluid contents of the cavity gradually become absorbed, and its walls close in and contract in the same way as do those of an apoplectic cyst. Indeed, in these last stages there may be some difficulty in discriminating between the two. In the remains of the apoplectic cyst, however, more colouring matter is usually found; its walls are also generally more dense and contractile, and there follows a more complete obliteration of the old cavity.

Lastly, there is a condition of the central ganglia of the brain, and more particularly of the corpora striata, which has been described by Durand-Fardel\(^1\) under the name of "état criblé." On making a section of these central ganglia, small pisiform cavities or lacunae, are occasionally seen, which sometimes seem bounded by a distinct membrane. Similar cavities may also be seen, though more rarely, in the pons Varolii. These are regarded by Laborde\(^2\)

---

1 Who, however, attaches little importance to this condition, and looks upon the little cavities as the results of dilatations of the vessels from long continued congestion.
2 Loc. cit. p. 94.
and others as minute apoplectic cysts, resulting from slight effusions of blood, whilst others again look upon them only as dilata-
tions of the lymphatic canals, in which, as pointed out by His,¹ the
cerebral vessels are contained. But Laborde thinks there is another
and more important modification of this condition, in which the little
cavities are somewhat larger, and are even capable of containing a
good sized pea, and in which no lining membrane is to be met with.
These he looks upon as the result of "une désorganisation partielle
et progressive," and as true, though minute and circumscribed, soften-
ings of the parts in which they are found.²

It only remains for me now to notice the forms of softening having
a post-mortem origin, and to point out how these may be distinguished
from those which have a pathological significance in consequence of
having been formed during life.

The most common kind is due to the combined influence of two
causes, namely, putrefactive changes, and the maceration of the
cerebral tissue from absorption of fluid.³ This is commonly met
with on the surface of the thalami and posterior portions of the
lateral ventricles, in cases where a long interval has existed between
the death and the autopsy, and more particularly when the atmo-
spheric temperature is high and the ventricles contain an excess
of fluid. In these cases the surface of the parts affected is broken
up, and presents an irregular appearance, whilst the tissue itself is
in a more or less diffusent condition. The fornix also frequently
shares in this process. It has been a subject of dispute as to
what is the nature of the process which gives rise to the soft-
ening of the central parts of the brain in hydrocephalus—whether,
in fact, it is due to an inflammatory process, or is merely the
result of maceration; and, if the latter, whether this has occurred
during life or after death, for many pathologists think it is doubtful
whether this mere physical process of maceration ever occurs during
life.⁴ When merely macerated nerve tissue is examined by the micro-

² Laborde says:—"Nous possédons plusieurs observations de ces curieuses désor-
ganisations partielles siégeant au centre de la produbrèance annuelle et paraissant
répondre, au point de vue symptomatique, à certains cas de paralyse diffuse, généralisée,
dans laquelle s'étendent progressivement un grand nombre de vieillards."—P. 95.
³ Dr. Bennett calls attention, in his "Clinical Lectures," to the softenings which may
be produced by mechanical means, owing to the clumsy use of instruments in removing
the brain and spinal cord from the body. This mode of origin should also be borne in
mind.
⁴ The impediment to the return of blood through the v. magna Galeni, owing to
thrombosis in these vessels, to which the collection of fluid in the ventricles is in part
due, also gives rise to a condition of oedema in the walls of the ventricles themselves,
and is followed by a true degenerative softening of the brain tissue. (Pathology of
Tuberc. Mening., Edinb. Med. Journ., April 1867.) Respecting this condition of oedema of
the brain, however, which it may be presumed occurs occasionally in heart disease and
others impeding the return of blood from the head, we have no very definite knowledge.
It seems doubtful whether any amount of serous infiltration would be capable of pro-
ducing actual softening during life, or do more than make the brain appear a little
moister than usual, and slightly lower in its specific gravity. The brain is usually said
to be "wet" when in this condition.
SCOPE, broken up and dissociated nerve elements only are met with, and
none of the granule corpuscles or other appearances characteristic of
real softenings produced during life. Examined by the specific gravity
apparatus also, we have several times found the actual density of the
altered tissue the same as that of contiguous unaltered portions. This
is somewhat remarkable and very characteristic, since if a portion of
brain tissue of the same apparent consistence, but having undergone
a pathological softening instead of a post-mortem maceration, had been
examined, the specific gravity would have been found from eight
to ten degrees of the hydrometer scale lower than that of similar
healthy tissue in the same brain. The specific gravity test thus
becomes a most important auxiliary to the microscope, and we have
several times found it most useful in examinations of the spinal cord.
Thus, a short time since, on making sections of a cord through the
cervical, dorsal, and lumbar regions respectively, the surfaces exposed
were quite pulpy and indistinct in the two former regions, whilst in
the lumbar portion the sections were firm, smooth, and distinct, and
yet the specific gravity in the dorsal region was the same as that in
the lumbar, whilst that of the cervical was even slightly higher, and
a microscopical examination, moreover, yielded no evidence of a
pathological change in any portion of the cord. We have found much
the same state of things also in other cases. Diminished consistence
or diffluence must not, therefore, be confounded with diminished
density or specific gravity; and it should be remembered that it
is the combination of the two, associated with certain microscopical
changes, which is the characteristic of real pathological softening
of the brain.

DIAGNOSIS.—1. Acute softening may, in its apoplectic form, be con-
ounded with congestion of the brain, with haemorrhage, or with
urinaemia; but by regard to the mode of onset of the symptoms, and
to their proportion inter se, a diagnosis may be established in the
majority of cases. At the onset of attack it may be impossible to dis-
tinguish the nature of the malady, but after a few minutes, or per-
haps after two or three hours, it is possible to aim at something like
certainty.

From congestive apoplexy softening may be distinguished by the
longer duration of mental obtuseness; and by the distinct limitation
of intellect in one or two directions, when the general obscurcation of
the "fit," or "stroke," has passed away. At the onset of attack in
congestive apoplexy there may be complete loss of consciousness, and
the same thing may occur at the commencement of acute ramollisse-
ment, and for precisely the same reason, viz., the presence of conges-
tion. In the former case, however, the mind rapidly recovers, and is
restored to its previous condition; in the latter all that was due to
mere congestion is speedily removed, but there remains the impair-
ment due to softened tissue. This may be aphasia, or some other
special alterations in the mental powers, such as have been described
in the section upon symptoms. Attacks of softening differ still more distinctly from those of congestive apoplexy, when they are unattended by any of the phenomena of hyperemia, and occur after middle life, and especially in advancing years. The patient becomes more or less suddenly confused, but does not lose his consciousness; he may wander in his talk, utter some exclamation of alarm, or may simply look distressed and as if about to cry; he knows what is said, and makes signs to those about him; is obviously aware that something very wrong has happened, and continues in this state of mental impairment for hours, weeks, or months. The difference from congestion is seen in the absence of great mental change,—loss of consciousness,— and in the persistence of limited intellectual failure.

These two classes of change in function, now described with regard to mind, are to be observed also in respect of sensation and motility. There may be, at the moment of attack, general anæsthesia and general paralysis; but if so, they are due to congestion or to shock, and they, with either of those conditions, soon pass away; leaving behind them, however, impaired sensation in one or two limbs, and with this, localised paralysis. On the other hand, there may be no general change in the power of feeling or of motion—there may be neither congestion, nor sufficient shock—the patient feels some numbness, coldness, or deadness, together with weakness of one or two limbs, and these conditions pass on into hemiplegia, i.e. loss of power, and loss or diminution of sensibility in the arm and leg of the side opposite to the lesion. Beyond these facts there is not unfrequently some hyperæsthesia or morbid sensibility of the paralysed limb, and this is much more common in cases of softening than in those of congestion; and, again, there is twitching of the limbs, or rigidity of those that are paralysed.

The general aspect of the patient differs from that of the person struck with congestive apoplexy. There is, unless congestion be present as a transient condition, pallor instead of dusky redness, coldness of head instead of heat, and a faint look in the place of bloated suffocation; there is often some sweat upon the brow; the patient is spare in habit, and the attack occurs when sitting quietly at the desk, or when making no such exertion as could tax the physical powers. Beyond these general conditions there may be observed rigidity of arteries, an irregular, weak, and often intermitting pulse, a feeble heart, arcus senilis, and irregular distribution of bodily warmth.

From hæmorrhagic apoplexy acute softening may be sometimes distinguished by the following considerations: In hæmorrhage there is often some evidence of either congestion or of shock; in softening there may be an entire absence of both. In hæmorrhage the attack frequently occurs at night; the patient goes to bed apparently well, and wakes in the morning feeling as usual, but on attempting to move finds that one side is paralysed. In hæmorrhagic apoplexy the attack is often absolutely instantaneous, in softening it is gradual. In the former there may be not the least—even momentary—confusion of
mind, whereas in the latter there is distinct mental perturbation and insufficiency. In haemorrhage, when the intellect is profoundly affected, as it sometimes is at the onset of attack, there is often a rapid restoration, and in the course of a quarter of an hour the patient's mind is as clear as it was before; in softening per se there is less distinct mental obscurcation at the commencement, and little or no subsequent recovery. In haemorrhage there is sometimes alarm, and not unfrequently anxiety and depression, whereas in softening there is more commonly too much confusion of thought for any definite apprehension to be entertained, and sometimes there is transient excitement or mild delirium.

Sensibility is often unaffected in haemorrhage, it rarely escapes altogether in an attack of softening. In the former there is, as a rule, unilateral anaesthesia, which rapidly diminishes or disappears; in the latter there is dulness of sensation, with morbid feelings of coldness, numbness, tingling, &c. which persist.

The paralysis in haemorrhage is, typically, hemiplegic, in softening it is more irregular, and more closely limited. In the former there is neither rigidity nor convulsion unless the coma be profound, and the paralysis extensive; in the latter there is often either twitching or tonic spasm even when the paralysis is slight, and the mental perturbation trivial.

In haemorrhage there is very frequently hypertrophy of heart, with granular degeneration of the kidneys; in softening there is more commonly a weakened heart, with valvular disease.1 Haemorrhage may occur in a person of strong limb and general good health, whereas softening is more common in the aged, the enfeebled, and those who have suffered from exhausting diseases, or still more exhausting cares.

From urinaemia as a cause, per se, of an apoplectic seizure, softening may be distinguished by the fact that in the former, convulsions of some kind and to some degree almost invariably precede the coma; and that these have followed premonitory symptoms of drowsiness, oppression, and headache. The coma exhibits in a marked manner the features sometimes observed in acute softening of the brain, viz. an apparent profundity, with susceptibility of being roused. Urinaemic patients lie in apparently profound torpor, but they may be roused by a touch or a word, and may appear in possession of all their faculties; left to themselves they relapse almost instantly into the state of stupor. In softening, if the coma be highly marked the awakening is less distinct, and the answers are less rational. In urinaemia there is often amniosis, and a generally obtuse condition of sensibility, neither of which are frequent in ramollissement. There is much twitching of the limbs, and often marked rigidity in the former case, but the locality of these symptoms changes from side to side, and is not accompanied by fixed

1 Dr. Kirkes found the heart hypertrophous in thirteen of twenty-two cases of cerebral haemorrhage, and in all of these the kidneys were diseased, being for the most part granular and atrophous. (Medical Times and Gazette, Nov. 24, 1855.)
paralysis; there may be twitching or rigidity in the case of softening, but these are found in the same limbs day after day, and are attended by distinct and persistent loss of power. The stertor in urinaemia is unlike that of softening, being oral rather than guttural;¹ the pulse-respiration ratio is much changed, being sometimes 5 : 1;² sensori-motility and irritability of muscles on percussion are often notably increased. Beyond these features there are the signs of characteristic debility and cachexia, the pale waxy skin, with vomiting and diarrhoea; and above all the oedematous condition of the eyelids and ankles, together with albuminous urine. In cases of acute cerebral softening, all these symptoms may be absent. The two diseases are frequently combined, but when they are so it is not impossible to determine how much is due to the one, and how much to the other condition.

When softening of the brain occurs in a convulsive form, its diagnosis is to be established by regard to the symptoms already described, p. 445. It is by a consideration of the prodromata and of the after-phenomena that the distinction may be made from epilepsy; it is by a similar process that tumour of the brain or of meninges may be diagnosticated.³ That which is characteristic of softening is not the fact of the convolution, nor the form which the convolution takes, but the gradual development of intellectual, sensorial, and motor failure, such as has been described in the section upon symptoms; and the absence of those general and special changes which are characteristic of tubercular, carcinomatous, or other morbid growths.

The form of softening which is marked by delirium is not likely to be confounded with any other malady. It is essentially an affection of old age, and may be distinguished from simple senile congestion by the persistence of its symptoms, and by the speedy development of those signs of failure in nerve-power, to which so much attention has already been directed.

2. Chronic softening, when its course has been chronic throughout, has to be distinguished from tumour and from meningitis; and although the distinction is not possible in all cases, approximation to certainty may be attained in the majority by regard to the following considerations.

In tumour there is pain, intense in degree, subject to violent exacerbations, limited to and fixed in one locality; the special senses are affected, so that there is blindness or deafness, or the two combined, on one side generally, but sometimes on both; there are local paralyses, and epileptoid convulsions; but, apart from the convulsions, unimpaired intelligence. There is often marked disturbance of the stomach, obstinate vomiting, and constipation; and there may be the signs of the tubercular, carcinomatous, aneurysmal, or syphilitic dyscrasias. In chronic meningitis, there is pain, generally distributed over the

³ See articles Epilepsy and Adventitious Products in the Brain.
SOFTENING OF THE BRAIN.

whole head, not very severe in degree, and, although varying in intensity, not subject to the paroxysmal exacerbations observed in tumours; there may be local paralyses, and these are especially observed in the muscles of the eyeball; there is much but intermittent mental excitement, and irritability of temper alternating with marked depression; there are disorderly spasms and paralyses of the limbs together with frequent but irregular accessions of fever; there is often a syphilitic taint, but there may be an entire absence of that dyscrasia, and the symptoms may have dated from a blow or fall.

In chronic softening there is dull headache, and gradual impairment of intelligence, motility, and sensibility, together with advancing years or a prematurely aged appearance, a feeble heart, rigid vessels, and most commonly some disease of old standing in such important viscera as the kidneys or the liver.

Thus, to resume, the characteristic feature of tumour is pain, that of softening is failure of power, that of chronic meningitis is the mixture of excited with depressed functional activity. It is the progressive deterioration of cerebral faculty which marks out the disease we are considering; the patient begins to die, as it were, before his time, and his death begins in the highest element of his organism.

PROGNOSIS.—Occasionally there is complete recovery after an attack of acute softening; for example, apoplectic seizures have occurred, have been followed by hemiplegia and mental dulness of many months' duration; these symptoms have passed away entirely, and upon post-mortem examination, after a number of years have elapsed, the signs of old softening have been distinctly discernible. It is possible, of course, that the softening may have originated in or around a "clot," but that possibility does not affect the general question of prognosis. Again, there may be improvement, but not complete recovery; a patient may suffer a sudden apoplectic seizure, and may lie for days in a state of profound danger, the mind almost a blank, and the limbs hemiplegic; but after a time he may improve, and his improvement may continue for months, slowly going on from week to week; he becomes able to understand what is said, to speak or to make intelligible gestures, he may walk, or may even regain the use of his hand, and may remain more or less aphasic for an indefinite period. He may have a second attack, and one so characterised as to show that the other side of the brain has been affected, and he may be partially restored from this. At length a third or a fourth seizure comes, from which there is no recovery. Upon post-mortem examination in such cases distinct softenings may be found in such situations as to relate them to the first or second attack, and the cause of such softenings may be discovered in the obstructed arteries. The prognosis of softening, therefore, although unfavourable, is not necessarily fatal.

The prognosis is relatively favourable when the patient is young, and has been previously healthy; as, for example, when an apoplectic
attack occurs during the course of rheumatic endocarditis in a young subject. It is unfavourable when the patient is old, or is affected by chronic disease of the kidneys, liver, or heart, when the arteries are rigid and the circulation low. It is favourable when the softening is, as it were, the result of accidental interference with the supply of blood; it is unfavourable when that interruption of the arterial circu-
lation is but part of a general organic change.

The severity of an attack is to be judged of by regard to its mode of onset. If accompanied by either much congestion or by profound collapse the symptoms, although very highly marked and widely distributed, may pass away; whereas the same amount of symptoms occurring without evidence of congestion or collapse would indicate, in direct proportion to their severity and extent, the gravity of the lesion. Cæteris paribus, the lesion is in proportion to the extent of the symp-
toms; and the prognosis is worse when the mind, sensation, and motion are all slightly impaired, than it is when either one of them alone is profoundly affected.

If the patient be young, and if there be no signs of general impair-
ment of nutrition, hopes may be entertained that there will be some recovery of mental and motor power, but if the patient be old, or if there be weak circulation, and rigid vessels; and if the attack has had many forewarning symptoms, such as occasional forgetfulness, numb-
ness of the extremities, and the like, the probability of restoration is very small, while the likelihood of increasing mischief or of renewed seizure is very great.

The prognosis of approaching death after an apoplectic or convul-
sive seizure is based upon the increasing rapidity and feebleness of pulse, the involuntary passage of the urine and faæces, and the general flaccidity of the limbs.

**TREATMENT.**—Attacks of softening may be postponed by attention to the following points:—1. The maintenance of an even temperature in the body: the feet and hands when chilly and blue should be put in hot water, or wrapped in and rubbed with warm flannels, and the patient should be placed in the recumbent posture, with the head only slightly raised. 2. The avoidance of long intervals between meals; food, easy of digestion, should be given frequently, and the patient, if old, should not be allowed to pass the night without nourish-
ment. 3. The ready administration of some gentle stimulant when there is any tendency to occasional pallor or faintness. A glass of wine, or some sal volatile and water, should always be at hand and should be given, not recklessly, but fearlessly if the premonitory symptoms become threatening. 4. Direction of the mental habits; easy and pleasant occupation of the mind, with careful abstinence from lazy inaction on the one hand, or violent excitement on the other. 5. Careful attention to the excretions, the skin, the kidneys, and the bowels. Exposure to cold is very prejudicial, and, although constipation and straining at stool are to be strenuously avoided,
nothing is much more mischievous than the relaxation of close and too warm rooms, and the production, by medicines, of anything approximating purgation of the bowels.

When the premonitory symptoms are those of much headache and drowsiness, obvious relief may be gained by warmth to the extremities, and by the use of such diuretics as the liquor ammoniae acetatis, with infusum scoparii, nitrate of potass, and spirits of nitric ether, or of juniper.

When there is the tendency to nocturnal delirium, a judicious administration of liquid nourishment, with very small quantities of wine, may suffice to give relief. Should this fail, the most useful medicine that I know of is the Indian hemp, in doses of a quarter to half a grain of the extract.

If there are marked symptoms of spasmodic or convulsive character, bromide of potassium in doses of from five to fifteen grains may be given three times daily with a bitter infusion and some diffusible stimulant, such as chloric or nitric ether.

On the occurrence of an attack, either apoplectic or convulsive, there is but little that can be done beyond the regulation of temperature and of secretion that has been already described; but when the attack has passed away something may be gained by the administration of cod liver oil, hypophosphite of soda, and vegetable tonics. It appears to me highly doubtful whether under any circumstances of softening of the brain the smallest good has followed either general or local blood-letting, the application of blisters, the administration of mercury or of iodide of potassium.

When recovery has advanced to a considerable degree, and some limbs remain paralysed, good has distinctly followed the exhibition of strychnia in exceedingly small doses, and the cautious application of galvanism to the weakened muscles.
ADVENTITIOUS PRODUCTS IN THE BRAIN.

By J. Russell Reynolds, M.D., and H. Charlton Bastian, M.D.¹

In this chapter is included a description of many diseases differing widely from one another in their pathological character, but agreeing in this, that they lead to the development within the cranium of some abnormal physical conditions, the nervous symptoms of which may bear close resemblance, inter se, during life.

Symptoms.—It has sometimes happened that, on post-mortem examination, tumours have been found in the brain, the existence of which had never been suspected during life. The patient may have presented no sign of cerebral disease, and may have died from an affection of the lungs or other organs; and, with the help conferred by post-mortem discovery upon the direction of questions as to past history, no evidence can be obtained of any symptom which can be referred to the brain. Such a case occurred to myself some years ago; several large hydatid growths being found in the brain of a young girl who had never suffered in any such way as to lead to the suspicion of cerebral mischief. These facts should be borne in mind when dealing with certain cases where signs of cerebral disease are present, but the diagnosis is obscure. When it is said that "a tumour cannot exist because of the absence of this or that symptom," it should be replied, that a tumour may exist without any symptoms at all.

There may be very highly marked symptoms, and yet these may be of such a character as to mislead. Dr. Abercrombie² has related examples of disease within the cranium, the locality and nature of which had been unsuspected during life, the patient's history having been such as to lead to a diagnosis of some affection of the stomach. Cases of the kind described by Dr. Abercrombie are rare, and it is probable that they will be rendered more so, as clinical examination becomes more minute. The fact, however, remains, that the complaint of a patient may be so marked with regard to dyspepsia, vomiting, constipation, and the like, and so trivial in respect of headache, giddiness, or other morbid sensations, that, although he has a tumour in his brain no suspicion may be entertained of its existence, and the diagnosis that is arrived at may be malignant disease of the pylorus, or the liver.

¹ The section on Morbid Anatomy is written by Dr. Bastian.
² Practical Researches, p. 337.
In other cases the symptoms of tumours are highly characteristic, and the diagnosis of their existence, their exact situation, and anatomical nature, may be sometimes made with a precision and minuteness such as is scarcely attainable with regard to any other diseases.

The intellectual faculties may be unaffected, indeed, they very often are retained in their integrity when other functions of the brain are seriously impaired. The changes they present are of two kinds; there may be on the one hand, great irritability of temper, a condition totally different from the previous habit of the individual, and with this, but very rarely, some mild delirium, or confusion of thought; on the other hand, there may be loss of memory, and general impairment of intelligence, with depression of spirits and listlessness. When convulsions occur, as they frequently do, during the few days that precede death, there may be profound coma as their sequel; but the convulsions which exist in the earlier period of the growth of tumour are often accompanied by only partial loss of consciousness, and are followed by none of the stupor which is so commonly observed in epilepsy.

Sensation is altered in various manners, but by far the most characteristic change is that of pain. Headache is often slight at the commencement, but afterwards it arrives at great severity; it is usually confined to a definite point or region of the head, and persists in that locality; it undergoes occasional exacerbation, and sometimes the suffering seems almost intolerable, and elicits from the patient agonising cries; it is, however, rarely absent altogether during the intervals of paroxysm; it is increased by intellectual and physical exertion, by emotional disturbance, by sensational impressions, and by forced respiratory movements. It is sometimes almost the only symptom, but in rare cases it is absent altogether. The aggravation of pain which is occasioned by light, or noise, or movement, is such as to make a patient hold his head steadily between his hands, or bury it in the bed-clothes; and this intolerance has sometimes been regarded as hyperesthesia, from which it differs widely. The sight and the hearing may be dull, but yet sensorial impressions intensify the headache. The sense of sight is often lost in one eye or in both; or there may be simply some mistiness or imperfection of vision, with dark or bright spots before the eyes. The iris does not often lose its irritability, but it is often found diminished; whereas, in some cases of complete blindness, it contracts readily on the admission of even a feeble light. Hearing is less commonly impaired, but it may be lost completely on one side without having attracted the attention of the patient; noises in the ears are common, either with or without any diminution of the faculty. Numbness, tingling, creeping feelings, sensations of heat or of cold, may exist in the limbs, or in certain tracts of skin over the trunk, and sometimes there may be distinct anesthesia of parts. Vertigo is frequent, and often most distressing; usually it is relieved by closing the eyes and maintaining perfect
rest; but sometimes it is aggravated by darkness, and the patient has

to maintain a fixed gaze in order to ward off the feeling. Commonly
the vertigo is of such a kind that the patient feels as if rolling over,
or swimming along in space; and it is comparatively rare to hear
complaint of the apparent rotation or motion of surrounding objects.
Affections of the sight have been found most frequently when the
tumour has occupied the anterior lobes of the brain, and least fre-
quently when in the posterior lobes or cerebellum.

In the cases which have been placed on record, convulsions have
occurred more frequently than paralysis, and among those which have
presented the latter, one half have exhibited the former. Convulsions,
of epileptic form, often occur during the few days that precede death;
but in certain kinds of tumour or of adventitious product in the brain,
epileptoid convulsions may exist for years, and the cases presenting
them may be termed "epileptic." When no general paroxysms occur,
there are, very frequently, clonic spasms or tonic contractions of the
muscles. As the result of an examination of a large number of cases,
it may be stated that convulsions are most common when the disease
is situated in the posterior lobes of the brain, or in the cerebellum,
and least frequent when the anterior lobes are affected; the distribu-
tion being exactly the reverse of that which pertains in regard of
amaurosis. 1

Paralysis is sometimes observed in one muscle of one eyeball, such
for example, as the external rectus, leading to convergent strabismus;
or in all the muscles supplied by the third nerve on one side, so that
ptosis and divergent strabismus, with dilated pupil are the results.
The speech may be also affected, the patient being unable to articulate
certain sounds; the facial muscles may be so paralysed as to produce
every degree of deformity; or the paralysis may be more widely dis-
tributed, and be hemiplegic, or, but more rarely, paraplegic in its form.
Sometimes the lesion may be of such kind and in such degree, and
locality, as to affect the nutrition of muscular and other textures. For
example, in a case under my own care, where a tubercular mass in-
volved the seventh nerve, and also the deep origin of the fifth, not only
was there loss of sensibility on one side of the face, but the temporal
muscle was much wasted, the conjunctiva and cornea became sloughy,
and the mucous membrane of the mouth was aphthous and studded
with vegetable parasites. The paralysis of cerebral tumour is deve-
loped—as a rule—slowly and insidiously; and when it occurs in one
of the limbs, is sometimes preceded by pain or some other alteration
of sensibility; but in a few cases it is produced as an "apoplectic"
phenomenon, and may be the first symptom to attract the notice of
either patient or physician.

The general symptoms of tumour of the brain vary almost inde-

finite, for they may be simply those of reflex or direct disturbance of
the stomach and other viscera, when hydatid or fibrous growths are
their producing cause; or they may be the special features of carci-

noma, tubercle, or syphilis, when any one of those dyscrasies is the primary fact in the formation of the adventitious product. Thus they may, on the one hand, be all-important, and may partially conceal the cerebral disease, on the other they may be so trivial as to awaken no attention; while in an intermediate group they may have such character and relation as to render it possible to make an accurate diagnosis of the nature of the lesion. Thus, there may be tumours on the scalp, or, in other regions, glandular swellings of strumous character; or there may be distinct evidence of syphilitic deposit, of carcinoma, or of aneurismal dilatation of the vessels. Tuberculosis gives rise to the most common form of tumour in the child or young adult, and syphilis is the next in frequency in early life or middle age; while carcinoma is prevalent in direct proportion to advancing years. Sometimes there is obvious alteration in the general contour of the head, but such change is almost confined to the period of growth; whereas in later years there may be gradual prominence of one eyeball, or the distinct pressure of a growth through the bones. Under such circumstances the diagnosis is tolerably easy.

As a rule the commencement of symptoms is insidious, and their progress slow; but sometimes after a few premonitory phenomena there is a sudden attack of convulsions, or an apoplectic seizure. Under such circumstances a diagnosis is possible only by a consideration of the subsequent history.

Diagnosis.—In some cases it is impossible to gain even a hint of the nature of the malady, while in others the diagnosis is as certain as that of any disease with which we are acquainted. If convulsions be the prominent feature of the case the diagnosis is to be made from epilepsy, and here the distinction depends upon the recognition of symptoms over and above those of the latter disease. The convulsions are commonly epileptiform in type, but very often they present these differences,—they are irregular in development, there is not absolute loss of consciousness, there is little or no asphyxia, and no subsequent stupor, while the spasmodic movements are more marked on one side than on the other, and they last for a longer time than is observed in epilepsy. In many cases the age at which they commence is so far advanced as to make epilepsy improbable, and there are symptoms, such as pain, affections of the senses, and paralysis—which do not occur in epilepsy. Again, the mental state in a person the subject of tumour may remain quite intact, and may fail to present the peculiar sluggishness which is often, although by no means invariably, the concomitant of repeated epileptic seizures. Epilepsy is essentially a chronic disease, the commencement of which dates from or soon after the period of puberty; it is characterised by fits of a peculiar type; and when uncomplicated it exists for years, and in the majority of cases without entailing any ulcer change in the functions of either brain or spinal cord. Tumour in the brain is of comparatively rapid development; it begins, as a rule,—to which there is the one exception of tubercular growth—
after adult age has been reached, and most commonly when the period of middle life is passed; and when convulsions are present they are by no means the prominent symptoms of the malady, for although often severe they may be cast into the shade by the violence of pain and the loss of special senses.

It is possible that the early and even some of the advanced symptoms of tumour in the brain should be confounded with, or passed over as hysteria. Such mistake can only arise through carelessness, or through a prejudiced mode of dealing with the obscure affections of women. Not long since a lady consulted me, who was supposed to be hysterical, and who had been treated upon that supposition. Yet her symptoms had not commenced until after thirty years of age; she had violent paroxysmal headache, was blind of one eye, and deaf of one ear, and the amaurosis and the deafness had crept on slowly. The distinction from hysteria may be made by regard to age, affections of the special senses, the absence of the peculiar mental condition of the hysterical patient, and the nature of the paroxysms.

Chronic meningitis may be of such character that its symptoms pass into those of tumour. This is the case, for example, when there is syphilitic thickening of the membranes, which may at any time become so complicated by nodular thickening of either the membranes or the bones, as to give rise to the special symptoms of tumour. Again, a tumour, of fibrous or carcinomatous character, the growth of which is habitually slow, may sometimes set up, in its neighbourhood, chronic meningitis, so that the symptoms of the two conditions may be found in association. Under either set of circumstances the diagnosis is possible by a regard to the mode of development of, and relative proportion between the symptoms. As already stated (see p. 474), the distinction between tumour and meningitis lies here—that in the former the characteristic features are violent pain, marked loss of one or more of the special senses, integrity of mind, and occasional epileptoid convulsions; whereas in the latter the pain is slight, the special senses are perverted but not lost, the mind is damaged, and the convulsions are less distinctly epileptoid. In the former there is the predominance of pain, in the latter there is no such predominance, but a mixed condition of excited and diminished action in mind, sensation, and motility. It must be remembered, however, that the diagnosis may often be carried to this point,—the obvious presence of chronic meningitis, and the probability of tumour; but this latter cannot be decided because of the absence of its special symptoms (see page 479). On the other hand, in certain cases, there may be no doubt of the existence of a growth, when paroxysmal pain, &c. occur in a patient of obvious carcinomatous constitution.

From chronic softening of the brain, the diagnosis is to be made by recognising the absence of the characteristic features of that malady, viz. loss of mental power, of sensation, and of motility. Certain cases of tumour may be taken for examples of chronic softening, and they are such as have been marked by a small amount of pain, by repeated
convulsions, and gradual failure of intelligence. It would be impossible under such circumstances to make an accurate diagnosis.

The diagnosis of the particular locality of a tumour may sometimes be very minute and accurate, but in other cases vague, and not frequently erroneous. The side of the brain affected is usually, but not invariably, the same as that upon which the pain is felt, and on which the special senses and the muscles of the eyeball are affected; it is the opposite to that upon which spasm or paralysis occur in the limbs. Again, the locality of pain may be taken for a guide as to the situation of a tumour in the anterior, middle, or posterior lobes. Such guide, however, is not always trustworthy, for frontal pain may be the result of a cerebellar tumour. Upon analysing a large number of cases, I find that convulsions are most frequent in tumours of the cerebellum, and that they diminish in frequency as the seat of lesion advances forwards, i.e. through the posterior and middle to the anterior lobes of the cerebrum; and that amaurosis, impaired articulation, and intelligence observe a contrary relation to those lobes, being most common when the tumour is in the anterior cerebral lobes, and relatively less frequent as the seat of tumour retrogrades. Romberg has suggested that the position of a tumour on the upper surface or at the base of the brain might be determined by an observation of the effect produced on pain by forced inspiration or expiration; the pain of tumours, when seated at the base being aggravated by inspiration, that of those on the upper surface by expiration, sneezing, or coughing. This Romberg explains by the rising and falling of the brain during the respiratory movements, and the consequent pressure of the mass against the upper or lower bony walls.¹ I have met with several cases which confirm Romberg's statement, but several others in which no reliance could be placed upon the test. The particular portion of the brain involved in a tumour may be sometimes determined by a careful consideration of the distribution of all the symptoms; such diagnosis, however, requires merely the application of anatomical and physiological knowledge, and needs no further notice here.

A diagnosis of the nature of a tumour is always of great importance both in regard of prognosis and of treatment. Sometimes all that can be accomplished is a guess, but sometimes tolerable certainty may be attained. Under certain circumstances we may distinguish between tubercle, hypertrophy, syphilis, lead-poisoning, aneurism, hydatids, and carcinoma.

Tubercle is the most common form of tumour in the child or young adult, and we might infer its presence if, in addition to a tubercular family history, there were the obvious features of the tubercular constitution, together with an elevated temperature, and the presence of tubercular disease in the lungs or bronchial glands. It is somewhat curious to observe that the temperature of cases of cerebral tuberculosis is not raised to the degree, nor with the persistency, that is to be

noticed in regard of tuberculosis elsewhere. After puberty an examination of the chest is of great importance in the diagnosis, since it rarely happens that a healthy state of the lungs is found co-existent with tubercular disease of the cranium.

Hypertrophy of the brain, although not an adventitious product, is best described in this place. It may be met with in young children; but the only characteristic feature of the disease is enlargement of the cranium. Dr. West observes that this is "first apparent at the occiput, and the bulging of the hind-head continues throughout especially striking. The forehead may, in the course of time, become prominent and overhanging, but the eye remains deep sunk in the socket, for no changes take place in the orbitar plates, such as are produced by the pressure of fluid within the brain." There is no prominence, but actual depression, of the fontanelles and sutures; the general nutrition of the child is imperfect, but there is nothing special in the cerebral symptoms which would lead to the diagnosis of this particular form of malady. Partial hypertrophy of the brain may be attended by no disturbance of the cerebral functions; the morbid condition, under such circumstances, can be recognised only by post-mortem examination.

Syphilis may occur in such locality as to produce any of the varied symptoms which have been enumerated; but there are certain features which help to distinguish it from other forms of adventitious products in the nervous centres. Headache is rarely intense, but is prone to nightly increase; actual loss of sight or hearing is not common; implication of the third, and especially of the sixth nerve, is very frequently observed, so that the patients exhibit ptosis, dilated pupil, and divergent strabismus, or more commonly inversion of the eyeball; there is often much depression of spirits, and further a wide extent of symptoms, the spinal cord as well as the encephalon being involved in the mischief. The characteristic features of this disease are, however, to be sought elsewhere, in the presence of periosteal thickening, eruptions on the skin, and such other phenomena as have been described in the article on Constitutional Syphilis.

The intoxication of lead may be followed by such induration of brain substance as shall produce the symptoms of tumour; but the diagnosis turns upon a consideration of the previous history of the case, and the discovery of exposure to lead by trade, accident, or medicine; the previous occurrence of symptoms of lead colic; the presence of general cachæmia, of a blue line on the gums, and of lead in the secretions. The extensors of the hands and fingers are especially paralysed; the extensors of the toes, and particularly the tibialis anticus, may be equally affected; the paralysed muscles become much impaired in their nutrition, and exhibit marked diminution, even extinction, of both contractility and sensibility on the

3 Vol. i. p. 313.
application of powerful faradisation; but yet they may respond readily to an interrupted battery-current of moderate power.

Induration of the brain may occur in scorbutus, in rickets, or in epilepsy, but the diagnosis of its presence in either condition would be attended with much difficulty during life. Dr. Cohn observes that in one case, there was, in the instance of rickets, an entire want of intellectual disturbance; whereas in epilepsy,—as described by Bouchet and Cazauviel, and as observed by myself,—the presence of induration might be inferred from the progress of general intellectual decay; attention, apprehension, memory, and judgment failing; the patient becoming gradually incoherent, and general paralysis creeping on, while the fits increased in frequency but diminished in violence.

The aneurismal nature of a tumour could be guessed at only per viam exclusionis, or rendered probable by the observation of disease of similar kind in other portions of the arterial system; and precisely similar remarks may be made with regard to hydatid growths.

The presence of carcinoma would be inferred only upon the recognition of the cancerous cachexia; and here age would be an important element in the consideration. Lancinating pains in the limbs are not, as Rostan supposed, of any diagnostic value; but the diagnosis must rest upon the discovery of the carcinomatous dyscrasia, and the co-existence of tumours elsewhere, and especially of such as affect the integument and bones of the skull.

MORBID ANATOMY.—In this place we do not profess to give an account of intra-cranial adventitious products as a whole, but shall strictly confine ourselves to such products or growths as have their seat in some part of the encephalon, and we must refer to another article for a description of the morbid growths which take origin from the meninges. Whilst it is indispensable, for the sake of precision, and from a pathological point of view, to refer to these growths under different heads, it must not be supposed that we are able clinically to exercise the same precision. And, unfortunately, during the life of the individual it is often absolutely impossible to determine whether a new formation, imagined to exist, has originated in the midst of the brain substance, or, having sprung up from one or other of the meninges, has merely grown into or pressed upon this secondarily. In both cases the symptoms produced may be almost identical. Similar effects are also, very rarely, produced by the extension of an external morbid growth inwards through the orbit.

In addition to the adventitious products more strictly so called, such as blood-clots, hydatids, &c. many varieties of tumours are met with in the encephalon. As in other parts of the body these often present unmistakeable characters, though occasionally their histolo-

1 See Cohn, in Gubab. Zeitschr. v. 35, 1854, or Schmidt's Jahrb. Bd. 86, 1855, No. 6, p. 322, and Bouchet and Cazauviel, De l'Épilepsie dans ses Relations, &c.

2 Recherches sur le Ramollissement, p. 404.

gical composition is so indefinite as to make it extremely difficult to classify them. They exist either as distinct growths, with sharply defined outlines, or they may be, as it were, infiltrations passing insensibly, at their circumference, into the surrounding brain tissue. In the former case they are often inclosed in a fibrous envelope, of more or less thickness, which now and then may be found in a calcified condition; whilst the brain tissue around may be quite firm and healthy, or softened to a variable extent. The softening may be simply white, or, if there had been much antecedent congestion, may exhibit various shades of red, whilst in other cases the yellow gelatinous softening is met with, such as Rokitansky\(^1\) and Cruvelhier\(^2\) have described. This seems to occur most frequently around cancerous growths. At other times the brain tissue around adventitious products is condensed and indurated.

Other adventitious products, such as silver and lead, are met with only in minute quantities, and are for the most part diffused through the substance of the brain. Not being collected into distinct aggregations, we require the aid of the chemist to recognise their existence. Saline matters, also, either abnormal in kind or in quantity, may be diffused through the tissue of the nervous centres, when the nutrition of these falls and the brain matter undergoes certain modes of degeneration. This is a subject on which our knowledge is very defective.

The various new formations and foreign bodies met with in the substance of the brain may be thus arranged, though they will not all be treated of in the present article:

1. Tubercle.  
2. Syphilitic growths.  
5. Gliomata.  
6. Fibro-plastic tumours.  
7. Fibrous do.  
8. Osseous do.  
9. Tumours of the pituitary and pineal bodies.  
15. Plastic lymph on walls of ventricles.  
17. Calcareous and other concretions.  
18. Entozoa \(\{\) Cysticerci.  
19. Silver and lead.

1. Tubercle.—Tubercle in the brain is much more frequently encountered in children than in adults, but, as pointed out by Andral, it is not commonly met with in children under two years of age. The period of maximum frequency is thought to be from the third to the seventh year inclusive. It rarely occurs in the brain in children without at the same time existing in some other organ of the body. In 117 examinations of adults who had died of phthisis, Louis met with tubercle in the brain only in one case, whilst MM. Rillic\(^3\) and

Barthez discovered masses of tubercle in the brains of 37 out of 312 children in whom this morbid deposit existed in one or other of the remaining organs of the body.

Sometimes a single mass of tubercle exists in the brain, sometimes two or three, and at others a large number of smaller masses. In size the separate masses vary between that of a millet seed and a large hen's egg, those most commonly met with, however, being about equal to a filbert or small walnut. They are mostly spherical in form, but are occasionally more or less lobulated. All parts of the brain, from the surface to the centre, are occasionally the seat of this deposit. Perhaps, having regard to its size, the cerebellum is the most favourite seat of tubercle. It is so regarded by Dr. Wilks and Dr. Jenner, and Andral was, doubtless, of the same opinion, since, without regard to size, he placed the cerebellum second, after the cerebral hemispheres, in the order of frequency of site. After these, in order of frequency, Andral names the pons Varolii, the medulla oblongata, the spinal cord, the peduncles of the cerebrum and cerebellum, the optic thalamus, and the corpus striatum. Very frequently when masses of tubercle are situated in or upon the cerebellum, by their pressure they impede the return of blood through the venæ magna Galeni, or straight sinus, and so cause effusion of serum into the ventricles, and all the symptoms of chronic hydrocephalus. Very rarely, almost the whole of the cerebellum, or one of its lobes, may be, as it were, replaced by tubercular matter.

The usual condition in which tubercle is met with in the brain, according to Rokitansky, is in the form of masses of the size and shape already mentioned, "of a yellow or yellowish-green colour, of the consistence of lard or cheese, and firm, but easily lacerable." It is remarkable that the grey, translucent form of tubercle is rarely, if ever, met with in the brain. Lebert says he has seen it rarely, and Rokitansky believes that "there are some rare cases which prove that tubercle in the brain does, in part at least, commence in the grey translucent form, for portions of a tubercular mass are sometimes found in that state." He believes that it rapidly passes over from this form into that of the yellow cheesy tubercle. So far he is very much in accord with Virchow, who holds that each mass of cerebral tubercle, is in reality made up by the aggregation of a multitude of small milliary tubercles. Each mass is formed, not by the growth of one original focus, but "by the continual formation and adjunction of new foci at its circumference." He adds:—"If we examine one of these perfectly yellow, white, dry, cheesy tubera, we find immediately surrounding it a soft, vascular layer which marks it off from the adjoining cerebral substance—a closely investing areola of connective tissues and vessels." In this layer the young granules are formed. They are continually produced at the circumference, "and the large

1 Wilks' Path. Anat. 1859, p. 158. This fact is strongly insisted upon, also, by Dr. Jenner in his clinical teaching.
3 Cell. Pathol. transl. by Chance, p. 477.
4 Milliary tubercles.
tuber grows by the continual apposition of new granules (tubercles), of which every one singly becomes cheesy.\textsuperscript{1} But though this is the condition in which growing masses of tubercle are met with in the brain, at a later stage the process of increase stops, and a fibrous envelope gradually forms round the mass, so as completely to isolate it from the surrounding brain tissue. This condition is so general that many pathologists have held that all tubercles occur in an encysted condition in the brain.\textsuperscript{2} The thickness of the fibrous envelope varies with age—it may be an almost imperceptible layer of fibrous tissue, or it may attain a remarkable thickness and an almost cartilaginous consistence. Occasionally, even, it becomes completely calcified.\textsuperscript{3} Softening is met with at times in the centre of the tubercular masses, and, very rarely, in encysted tubercle the whole contents undergo this change. Such a case is reported by Dr. Ogle,\textsuperscript{4} in which a cyst the size of a pigeon's egg, with thin and friable parietes, was found in the pons Varolii, containing a "yellow glairy fluid in which a number of light-coloured soft particles of albuminous matter existed." More rarely still, in the brain, the tubercular mass has been found to have undergone a process of cretification.

The brain tissue around masses of tubercle is often perfectly natural, at other times it may be congested, more or less softened, or even indurated.

2. Syphilitic Growths.—These are very rarely met with in the substance of the brain. Instances have, however, been recorded. Dr. Aitken saw a "gummatous tumour" occupying the left optic thalamus, in a patient of Dr. Goodfellow's, who had suffered from syphilis, and some of whose children had died from inherited secondary syphilitic lesions.

Dr. Wilks has never seen independent tumours of this kind in the cerebral substance, though he believes, from the symptoms observed in some cases, that such deposits were very likely to have existed. A firm, tough, yellowish lymph-like mass of syphilitic origin has frequently been met with intervening between, and connecting the dura mater with the brain. Although it seems most probable that the primary seat of this is the dura mater, still it is desirable to mention it here on account of the serious way in which the brain matter is often implicated. Dr. Wilks records\textsuperscript{5} a characteristic example of this kind of lesion, met with in the post mortem examination of a woman of low character, who was believed to have suffered from syphilis. He says:—"At the anterior fossa the dura mater was united to the bone by a firm, yellow lymph;

\textsuperscript{1} Although differing so widely in their views as to the nature of tubercle, Rokitansky's description of the circumference of these masses in the brain is almost identical. He says:—"An extremely moist and jelly-like cellular structure connects the tubercle with the surrounding cerebral tissue. * * * This stratum further contains, scattered mostly through its inner part, some small grey or greyish yellow tubercles, which occasionally unite with the great central mass."—Loc. cit. Vol. iii. p. 429.

\textsuperscript{3} Dr. Ogle, Brit. and For. Rev. Oct. 1864, p. 463.

\textsuperscript{5} Guy's Hosp. Rep. 1863, p. 49.
Here also the bone was slightly roughened, but not carious. The dura mater on the inner side was firmly and inextricably united to the anterior lobes of the brain, especially on the right side, and corresponding to the anterior fossa of the skull. On attempting to separate them, a quantity of hard yellow material was seen uniting them together. This filled up the sulci, and involved the cineritious substance. On the right side it had penetrated to the medullary matter, and here the adventitious substance formed a tumour, tolerably circumscribed on its deep side, the size of a walnut." In the liver were some of the characteristic tough masses, corresponding with a puckered and cicatriform condition of the surface above them.

3. Cancer.---Cancerous growths in the brain are, according to Lebert, decidedly more frequent in the second half of life, though they are met with occasionally in youth, or even in childhood. Dr. Walshe also found that out of 56 persons affected with cerebral cancer, 26 died between the ages of 40 and 60 inclusive, whilst 5 died before the 10th year, and 5 between the 10th and 20th years. In about one half of the total number of cases, cancer of the brain is primary.

All three forms of cancer may occur in the brain, though encephaloid is by far the most common: next to this Lebert speaks of a lardaceous intermediate kind. It may exist either in the form of a distinct tumour, or it may infiltrate parts of the brain. The growths are usually solitary, though occasionally two or even more may be met with. The size of the cancerous mass varies from that of a pea up to an orange, or even larger. Occasionally the greater part of one hemisphere may be implicated. The cancerous mass is very rarely inclosed in a sort of fibrous cyst, but in the majority of cases it passes, at some part of its periphery, almost insensibly into the adjacent brain tissue. The colour is occasionally the same as that of brain tissue, though various tints of rose, yellow, and even green may be met with either singly or intermixed. Very many cancerous growths in the brain have a yellow colour. All parts of the brain are liable to be affected. Tumours are frequently found imbedded in the midst of the hemispheres, and according to Lebert those near the convexity usually attain the largest size, whilst those in the pons and medulla are usually the smallest, owing to the more rapid death of the patient. The duration of life varies considerably; thus in 6 out of 11 cases inquired into by Lebert, the growth seemed to have proved fatal in about 6 months, whilst in 4 the symptoms extended over a period of from 2 to 5 years.

The consistence and amount of vascularity varies much in different cases. Effusions of blood may be met with in the midst of soft cancerous masses, and not unfrequently cysts are developed in their interior, which contain a thick glairy fluid. The surrounding brain tissue may be natural (which is frequently the case), or it may be softened, or, still more rarely, in a state of induration. The softening may be white, red, or of the yellow variety.

1 Dr. Ogle, in Journal of Ment. Sc. 1864, p. 229, cases 1 and 4.
Lebert records one instance of a cerebral cancer by its growth causing a large perforation of the skull, in the situation of the coronal suture.

4. Melanotic Tumours.—These are found in the shape of small nodules, generally varying in size from that of a pea to a bean. They may exist in the deeper parts of the brain, or at its surface, in the grey matter of the convolutions. Sometimes these growths may be cancerous in their nature, but others are certainly not so. The black colour is due to the infiltration of the cells of the growth with black granular pigment, similar to that met with in the choroid coat of the eye. Dr. Clendinning\(^2\) found a mass of melanoid deposit in the upper part of the right corpus striatum, as large as a horse-bean, and external to this, a hard pea-sized mass. Similar deposits existed in the centrum oval, and in the right lobe of the cerebellum. In this individual, growths of the same kind existed also in great numbers in the subcutaneous tissue, and in most of the internal organs except the lungs.

5. Gliomata.—These are growths, named by Virchow, which take their origin in the neuroglia or interstitial connective tissue of the brain. They are, in fact, formed by a localised hypertrophy of the neuroglia, and contain no nerve elements in their composition. These tumours are never sharply defined from the surrounding brain tissue, to which they bear a certain superficial resemblance. On section, however, they are seen to have a somewhat translucent, bluish-white appearance, whilst at the same time they are firmer and rather more vascular than the brain tissue itself. These tumours are usually solitary, and of slow growth, so that they may exist for a long time without producing any very appreciable symptoms. They often attain to a considerable size, that of an orange for instance, and are occasionally even much larger than this. They are most frequently met with in one or other of the posterior cerebral lobes, and after this, perhaps, on some part of the upper and outer part of one of the cerebral hemispheres. The tumours are composed of an intercellular substance, which varies in quality and consistence in different parts of the brain, and of an abundant mixture of cells and nuclei. The cells are variable in shape and size, and the smaller ones occasionally possess fine prolongations which are continuous with those of adjoining cells. There are two principal varieties of gliomata: the soft and the hard. The former containing a soft basis substance, and numerous moderately large cells, are closely allied to medullary sarcoma; whilst the latter having a harder and firmer basis substance and small cells with highly refractive nuclei, have close affinities to fibrous tumours.

Dr. Cayley\(^3\) has recorded a case in which a tumour of this kind, about the size of a large walnut, involved all the deeper parts of the right side of the poux, the right processus ad testes, the corpora quadrigemina to some extent, the right half of the valve of Vieussens, and the fibres of origin of the right, fourth, and fifth nerves.

1 Hooper's Morb. Anat. of Hum. Brain, 1828, pl. xii. figs. 2 and 3. Trans. of Path. Soc. vol. i. p. 42. 3 Ibid. vol. xvi. 1865, p. 23.
6. Fibro-plastic Tumours.—These growths most commonly arise from the pia mater, still occasionally they take their origin in the substance of the brain. They have been found in the midst of the hemispheres, in the pons, and in the cerebral peduncles. They vary in size from a pea to a hen’s egg, are mostly spherical or ovoid in shape, with a surface sometimes mammilated or slightly lobulated. Their colour is generally rose, mixed with yellowish and even greenish tints. The amount of vascularity differs in different tumours, and in different parts of the same growth. They contract no adhesions, and do not infiltrate neighbouring parts, although they erode by their growth and consequent pressure.

Dr. Bristowe records ¹ a characteristic instance of the occurrence of a tumour of this kind in a man, aged 33 years. The growth was irregularly spherical, and about one square inch in bulk. It arose from the right half of the pons and the corresponding crus cerebelli, and extended partially into the medulla oblongata. The surface was lobulated, and had somewhat the appearance of brain substance, owing to its colour and the arrangement of vessels on its surface. There were no defined limits to the deep portion of the tumour, which passed insensibly into the surrounding brain tissue. On section, the substance of the growth was greyish and slightly translucent, interspersed with patches of congestion.

Dr. Ogle ² has reported a case of fibro-plastic infiltration, in which the new product, instead of forming a distinct tumour, had infiltrated itself into the tissue of the left optic thalamus, so as to make this body almost twice its natural size.

7. Fibrous Tumours.—These growths are very rare, and comparatively few cases are on record. They are mostly small and spherical, varying in size between that of a small pea and a walnut. M. Reignier ³ found a pedunculated growth of this kind of the size of a large filbert growing from the valve of Vieussens; and in the Trans. of the Path. Soc., vol. v. p. 18, an account is given of a fibrous tumour about the same size, which was found projecting into the left lateral ventricle, from the side of the corpus striatum. Lebert records two cases: in one a tumour of the size of a pea was found in the pons, composed of a firm, elastic, yellow, and somewhat gelatinous tissue, but presenting the usual microscopic characters; in the other, 17 fibrous tumours were situated upon the ependyma of the lateral ventricles, varying in size between a pea and a small cherry stone, and of a white, or slightly yellowish, or even rose colour in some places. On section they were homogeneous, and somewhat translucent. Several tumours were situated on the septum, and superficially they were all covered by epithelial cells, similar to those of the ependyma. The substance of the brain otherwise was apparently quite healthy, and there was no excess of fluid in the ventricles.

8. Osseous Tumours.—True bony growths in the substance of the

¹ Trans. of Path. Soc. vol. vii. p. 28. ² Ibid. vol. vii. p. 12, pl. ii.
brain are extremely rare, still they have been met with. Dr. Bristowe\(^1\) found a growth of this kind occupying the position of the infundibulum and corpora albicania. It was a hard conical mass, about as large as a horse-bean, whose apex rested on the pituitary body, and whose base assisted in forming the floor of the third ventricle. It "was wholly unconnected with the dura mater or osseous parietes of the skull." On microscopic examination, it presented the characters of true osseous tissue, with perfect lacunae and canaliculi.

9. Tumours of the Pituitary and Pineal Bodies.—Both these bodies are occasionally found in a morbid condition, and more or less enlarged. Cysts are then frequently met with in their interior.

a. Pituitary Body.—Lebert considers the enlargement of this body to be a kind of hypertrophy. Several cases are on record. In one of these, related by Rayer\(^2\), this body was about 1\(\frac{1}{2}\)" in diameter, and its tissue was more dense and resistant than natural. Vieussens\(^3\) found it as large as a hen's egg, soft, and containing in its interior a greyish-white glutinous fluid. Heslop's\(^4\) records a remarkable case in which the tumour was soft, deep grey, and of the size of a large walnut, containing a small cavity with fluid in its interior. It occupied the region of the pituitary body, but also extended posteriorly as far back as the pons, and antero-laterally to the fissures of Sylvius, so as to occupy the whole interpeduncular space. The corpora quadrigemina were flattened antero-posteriorly, from pressure. Abercrombie\(^5\) also refers to a case described by Dr. Powell, in which there was found "a tumour, the size of a hen's egg, containing a thick purulent fluid under the anterior part of the brain, and interposed betwixt the optic nerves, which were much separated by it from each other. Below, it was attached to the pituitary gland, which was very soft, and enlarged to five or six times its natural size." Davaine's\(^6\) records three cases in which small cysts (supposed to be hydatids) were found in the pituitary body.

b. Pineal Body.—Hooper\(^7\) says, speaking of this body:—"It is sometimes converted into a cyst, the whole of the natural structure being destroyed. This cyst is firm and membranous, and I have seen it of the size of a tamarind stone. The contents of one which I examined were, a turbid serous fluid, with small particles of solid albumen." Dr. Ogle\(^8\) also relates a case in which "the brain and membranes were natural, excepting that the pineal gland was exceedingly enlarged, and very adherent, posteriorly, and contained two

cavities, each full of transparent fluid, situated immediately below its investing membrane."

10. **Formation of Grey Matter upon the Ependyma of the Ventricles.** — Rokitansky and Virchow\(^1\) have both described the existence of cerebral grey matter upon the internal surface of the lateral ventricles, in situations where, naturally, grey matter does not exist. It occurs in the form of numerous small tubercles, from the size of a mustard seed to that of a cherry stone.

11. **Vascular erectile Tumours.**—These growths are very rare. Nevertheless, Lebert has given the particulars of five cases in which they were found. In all they were discovered post-mortem, but had given rise to no notable symptoms during life. In one of these cases the growth was lodged in the right lateral ventricle, and was a development from the choroid plexus, but in the other four the tumours were imbedded in the cerebral substance.

In the case related by Farre\(^3\) the growths were multiple; two of the same size being met with in the medullary substance of the left hemisphere, and several smaller ones in the corpora striata and cerebellum. Lebert\(^4\) himself has minutely described an erectile tumour, of the size of a hen’s egg, found in the posterior lobe of the right cerebral hemisphere, and Luschka\(^5\) met with one of the same size in the left anterior cerebral lobe, which was surrounded by softened brain substance. Lastly, Fœrster\(^6\) alludes briefly to an erectile tumour of the size of a nut, found in the grey cortical substance of one of the hemispheres, the cavernous spaces of which were found to communicate with neighbouring dilated veins. The tumours described by Lebert, Farre, and Guérard, were made up almost entirely of fine vascular ramifications.

12. **Aneurisms.**—The intra-cranial aneurisms which are best known are those occurring on some one or other of the larger arterial trunks at the base of the brain, or on some of the branches of the circle of Willis, contained in the pia mater, and therefore on the surface of the proper brain substance. Such aneurisms belong to the meninges, and will not be further referred to in this place. There are, however, aneurisms belonging to the encephalon itself, whose existence has only recently been discovered, and which are remarkable principally for their small size, and from their frequent numerical abundance within the same brain. These were first detected and examined by MM. Charcot and Bouchard,\(^7\) the latter of whom has shown, not only their frequent and close association with the phenomena of intra-cerebral hæmorrhage, but also their apparent dependence upon a certain general pathological condition of the small encephalic arteries, which may exist alone, or

may be associated in various degrees with the more familiar atheromatous degeneration. The pathological condition of the arteries favourable to the formation of these minute aneurisms is one of fibroid degeneration—a process of *sclerosis* in which there is brought about a great increase in the number of connective tissue nuclei on the perivascular sheaths, and also in the walls of the vessels, whilst the muscular fibre cells of the middle coat are gradually replaced by fibrous tissue. This change diminishes or even destroys the elasticity of the arterial coats, so that when, from any increase of the ordinary blood pressure, they have once become unduly dilated, they are unable to regain their normal calibre. In this way, by the incidence of increased pressure upon degenerated parts, are produced the various kinds of aneurismatic dilatation, whose characters differ according to the degree and extent of the morbid changes in the parts involved. Thus, we may have uniform dilatation of an arterial branch let, for a certain portion of its length, or this uniformity may be disturbed by constrictions at intervals. The kind of alteration with which we are more particularly concerned at present, however, and which is about the most frequent, is due to an altogether local and circumscribed change, and results in the formation of the minute and more or less spherical *miliary aneurisms*, as M.M. Charcot and Bouchard propose to name them.¹

These miliary aneurisms are very rarely met with before the middle of life, and are most common in the very aged. They are visible to the naked eye, and can be seen readily with the aid of a pocket lens. Their diameter varies between $\frac{1}{15}$ and $\frac{1}{3}$, and they are attached to vessels which seldom exceed $\frac{1}{4}$ in diameter. Sometimes only two or three can be detected in the same brain, though more frequently they exist in much larger numbers. Bouchard has found even more than one hundred in the same brain. They may be met with in all parts of the encephalon, though with different degrees of frequency. Hitherto they have been found most frequently in the optic thalami, and then, in decreasing order, in the pons Varolii, the cerebral convolutions, the corpora striata, the cerebellum, the medulla oblongata, the middle cerebral peduncles, and lastly, in the white matter of the cerebral hemispheres. When abundant in the convolutional grey matter, a number of minute and variously coloured spots may be seen, after the membranes have been stripped off, lying exposed on the surface of the convolutions; whilst, when sections are made, others may be recognised in the deeper strata of the grey matter. Whether occurring in this situation or in the more central parts of the brain the colour of these minute aneurismatic grains varies from a bright red or violet, to a yellowish or even black hue²; according as they contain in their interior

¹ Cruvelhier (Anat. Patholog. Liv. xxxii. pl. ii. fig. 3) figures and gives an accurate description, so far as it goes, of these very miliary aneurisms under the name of "apoplexie capillaire à foayers milliaires," He was therefore ignorant of their real nature, though perfectly familiar with their naked eye appearance.

² Occasionally this blood pigment, in the form of amorphous yellow grains mixed with hematoxidine crystals, may be principally collected around one of these aneurisms (which has been ruptured), though within its enveloping lymphatic sheath.
normal fluid blood, or more or less altered blood pigment. Occasionally the aneurisms seem to undergo a natural process of cure. Their wall, as well as that of the enveloping and distended lymphatic sheath, becomes thickened by an increased growth of connective tissue elements, whilst at the same time the white corpuscles of the blood have a tendency to adhere to their inner surface. The fibroid change creeps on, bringing about a union between the wall of the aneurism and its sheath, the gradual thickening of these, and an extension of growth inwards, owing to a further organization of the adherent white corpuscles. Thus may the cavity of the aneurism be gradually diminished, till at last this, and even the minute vessel on which it is situated may undergo complete obliteration.

Such intra-cerebral miliary aneurisms may co-exist with other and much larger aneurisms of the vessels of the pia mater. Bouchard speaks of a case of this kind where the aneurisms of the arteries of the pia mater were not only exceedingly numerous, but varied in size between a pea and a cherry-stone. In other cases, minute aneurisms of these meningeal arteries may be met with precisely similar to those co-existing on the vessels in the midst of the brain substance. Frequently when miliary aneurisms are met with in the smaller cerebral arteries, the larger arteries at the base of the brain exhibit marked atheromatous changes: this coincidence, however, is by no means invariable.

Although the majority of intra-encephalic aneurisms are minute, and such as we have described, occasionally others of larger dimensions are met with. The size of the largest, however, could rarely exceed that of a small walnut, seeing that the arteries of the brain are comparatively small before they leave the pia mater to penetrate into its substance. I know of only five cases of this kind of aneurism on record, and in each of these the patient's death was occasioned by the rupture of the sac. The first case is related by Dr. Crisp,¹ and in this a boy aged fourteen died from the rupture of one of two small aneurisms on the anterior cerebral artery, in the substance of the anterior lobe. The aneurism which burst was as large as a horse bean, whilst the other was about the size of a pea, and was filled with laminated fibrin. The next was recorded by Dr. Van der Byl,² and was altogether remarkable from the fact that the aneurism, which was situated on the left posterior cerebral artery in the substance of the brain, was as large as a hen's egg, and was almost filled with laminated fibrin. In one case recorded by Dr. Gull,³ a small pyriform aneurism, "having much the appearance and size of a withered grain of wheat," burst in the centre of the pons varolii, and was found in the midst of a coagulum weighing two drachms. Dr. Gull gives the details of another case in which an aneurism about the size of a small filbert, situated on the left middle cerebral artery, in the anterior part of the middle cerebral lobe, was found in a girl aged seventeen, surrounded by a large recent

coagulum, and by softened brain tissue. The other arteries of the brain are said to have been healthy. Lastly, the writer has himself recorded a case\(^1\) in which an aneurism, about \(\frac{1}{3}\)" in length and of an elongated pyriform shape, with a distinct rupture in its larger extremity, was taken from the midst of an enormous effusion of blood into the outer part of the right corpus striatum and adjacent portions of the hemisphere. In this case there was an atheromatous condition of the arteries at the base of the brain, and, besides the larger aneurism, four or five of the small milliary aneurisms were found in different parts of the organ.

14. **Abscesses.** See *Art. Abscess in Brain.*

15. **Plastic Lymph on the surface of the Ventricles.**—A well-marked instance of this has been related by Dr. Wilks.\(^2\) It occurred in a man who had fractured his left orbital plate by a fall. A portion of the broken bone had torn through the dura mater and injured the anterior lobe of the brain, so as to lead to the subsequent production of an abscess in this situation. The man died after seventeen days: "on incising the roof of the ventricle (left) a membrane was found within it; and on cutting this through it was found to consist of a layer of lymph, which completely lined the cavity. Some purulent matter escaped from within it. It covered the roof, the floor, and extended from the anterior to the descending cornu, and was so tough that it was capable of being removed entire; it formed, indeed, a complete cast of the cavity, and resembled a croupous membrane, as seen on the trachea in inflammation of that organ. The surface of the ventricle was soft, and in parts tore when the membrane was removed; but in most places it could be cleanly taken off. The foramen of Munro was closed, and the right ventricle contained only some turbid serum." It was uncertain whether there was a communication between the abscess and the ventricle, but the lymph seemed to have been formed on the surface of the latter.

16. **Cysts.**—It seems extremely doubtful whether simple serous cysts are ever met with in the substance of the unaltered brain tissue. Those most likely to be of this nature are small cysts from the size of a pin's head to that of a mustard seed, which are sometimes met with beneath or projecting above the surface of the lateral ventricles. They occur either singly or in groups.

The corpora striata, on section, sometimes present the appearance of small cysts, even as large as a pea. These may be either sections of dilated lymphatic canals, or the remains of minute hæmorrhages or softenings.

It is true that larger cysts are not unfrequently met with in the brain, but these, when not due to one of the two forms of cystic entozoa, to be hereafter described, should rather be termed pseudo-cysts, since they are not primary formations, but have resulted from

---

\(^{1}\) Trans. of Path. Soc. vol. xviii. 1867.  
\(^{2}\) Ibid. vol. xv. p. 5.
the modification of pre-existing pathological states. They mostly
result from the later changes taking place in the seat of old effusions
of blood, or circumscripted softenings, or they are due to the softening
of encysted tubercular or cancerous nodules.

Cysts occasionally form in the substance of cancerous growths in
the brain, and as before stated, they have several times been met with
in enlarged pituitary and pineal bodies.

17. Calcareous and other Concretions.—These are not unfrequently
met with in the brain, and are mostly due to changes which have
taken place in masses of tubercle or in old abscesses. Such concretions
consist for the most part of phosphate and carbonate of lime, and only
a small quantity of animal matter. More rarely they seem to be the
result of previous effusions of blood: thus Lassaigues analysed a mass
which was found to be composed almost wholly of fibrine, and contained
only four per cent. of phosphate and carbonate of lime, with traces of
cholesterine.

Concretions known as "brain sand" are very common on or in the
pineal gland and its peduncles.

18. Entozoa.—Two kinds of parasites only have been met with in
the human brain, and these always in an immature or larval condition.
They are the Cysticercus, and the Hydatid or Echinococcus cyst: the
first representing the second, or scolex stage, in the development of
Tevnia Solium, and the other an equivalent stage of T. Echinococcus
which exists abundantly in its mature condition in the alimentary
canal of dogs. Goeze and Zeder have recorded two cases in which
they suppose the Conurus cerebralitis to have been met with, but they
have not been supported by other observers, and Davaine believes
these cases, in reality, to have been instances of hydatid disease.
Certainly, as he says, the descriptions these writers have given are
obscure and inexact, and we may well imagine mistakes to have been
made, considering the state of knowledge at the time in which they
wrote.

a. Cysticerci.—In the brain they vary in size from that of a pea to
a small horse-bean, or even larger. The serous cysts in which they
are usually inclosed, in other situations are often absent entirely, so
that they are bounded only by a smooth layer of unaltered or some-
what compressed brain substance. They often exist in large numbers
in the same brain, and are very rarely solitary. From ten to twenty
are frequently met with. Cruvelhier records an instance in which
more than 100 were found within the cranium of the same individual,
and of these about 50 were lodged in the cerebellum. They may be
found in almost all parts of the brain, but, speaking generally, they
are by far the most abundant at the surface of the brain, in, or in

1 Many cases are recorded by Dr. Ogle (Med.-Chir. Rev. July 1865, p. 212.)
3 Clinique Méd. t. v. p. 8.
4 Nachtrag zur Naturgesch. der Eingeweidwürmer 1800, pp. 300 and 313, tab. ii.

VOL. II.  K K
close connexion with the grey matter of the convolutions. They are extremely frequent in the pia mater, where they press upon and partially imbed themselves in the surface grey matter. Sometimes they are lodged completely in the substance of the grey matter, whilst more frequently still they are found between this and the white substance. They have also been met with in the midst of the white substance, in the central ganglia, in the pons, in the crura cerebri, and in the cerebellum as before stated. Cruvelhier has also seen real cysticerci in the choroid plexuses of the lateral ventricles, in which situation they have to be carefully discriminated from the small cysts so common in the same locality.

Although usually giving rise to but slight changes in the surrounding brain matter, the cysticerci themselves undergo important modifications with age. It is desirable that this fact should be known, in order that pathologists may recognise them in their different states, and that individual modifications may not be mistaken for specific distinctions. According to Davaine, 1 "Les altérations portent, d'une part, sur la vésicule qui est devenue plus ou moins globuleuse, plus volumineuse, sans jamais cependant avoir acquis un grand volume, irregulière, quelquefois divisée en lobules ou même double; d'une autre part elles portent sur la tête dont le rostre et les ventouses sont envahis par une matière noireâtre, pigmentaire. Les crochets sont recouverts à leur base par cette matière. Dans une période plus avancée on les trouve en désordre, diminués de nombres ou même ils ont disparu. L'ouverture de la vésicule rétrécie ou oblitérée ne laisse plus sortir le corps; la tête invaginée dans celui-ci ne peut non plus en être extraite par une pression ménagée; sa présence ne peut être reconnue que par la dilacération des parties." It should also be added that in those cases where the cysticercus is non-encysted, and lodged freely in one or other of the ventricles, it tends to grow more easily into the form of a tape-worm by the elongation and segmentation of the neck of the larval animal. 2

The cysticerci seem to occur pretty frequently in both sexes. They may be met with also at all ages beyond infancy, though, as Cruvelhier has remarked, they seem to be most frequent in the latter half of life, and have often been met with in very old people. 3

b. Hydatids. 4—In the brain, as in other organs, the hydatid or

---

2 Thus constituting the third stage of development, when the animal is termed a strobilus. See Brit. Med. Journ. 1852, p. 272, where a specimen, apparently in this stage of development, is recorded to have been met with in connexion with the fourth ventricle.
3 Dr. Cobbold says that more than 100 cases of cysticerci in the brain are on record. References to many may be found in his Entoœa, p. 224, and Professor Griesinger (Archiv. der Heilkunde, 1862) has analysed the details of between fifty and sixty of these cases.
4 The following remarks do not refer in any way to hydatids having their seat in or between the membranes of the brain. From various sources I have ascertained the details of 30 cases of hydatids contained within the cerebrum and cerebellum. I have seen references to a few other cases also, of which I have not been able to ascertain the
hydatids are mostly inclosed within an outer sac or cyst. In this organ, however, it is generally very thin, and in some cases it has been stated to have been altogether absent, the hydatid membrane pressing immediately against the compressed brain tissue. When they occur in the lateral ventricles the enveloping cyst is always absent. In the great majority of cases, only one hydatid cyst is met with, though this may contain two, three, or more hydatids of different sizes; usually, however, a single cyst exists containing a single hydatid. The size of the cyst varies generally from that of a marble up to a large orange, though occasionally this limit is much exceeded. Thus, in a case observed by Mr. Headington and reported by Dr. Abercrombie,1 an immense hydatid cyst was found within the left lateral ventricle, which nearly extended to the circumference of the brain on the same side, and “contained about sixteen ounces of limpid fluid;” and in another case, recorded by Rendtorff, an enormous mass of hydatids weighing two and a half pounds, was found in the same situation, in a girl only eight years of age. The cyst is frequently lodged in the centre of the white matter of one of the hemispheres, and it may increase in size till it occupies almost the whole of one of the lobes—anterior, middle, or posterior, as the case may be. Occasionally it occupies the greater part of two contiguous lobes, and may project towards the circumference, as well as into the lateral ventricle. In both these situations the cyst may be covered only by a thin layer of nerve substance, or it may be uncovered owing to gradual pressure and destruction of the same. I have only found one case recorded in which a hydatid cyst was lodged in the substance of the cerebellum; in this instance, however, it was large, measuring three inches by two, projecting into the fourth ventricle, and extending transversely across from the right to the left lobe, so as to have a coating of brain matter at each extremity not thicker than a wafer.

1 Diseases of the Brain, &c. 3d edit. 1836, p. 447, Case xxxii.

K K 2
A SYSTEM OF MEDICINE.

Although usually only one hydatid cyst is met with in the brain, still, sometimes two or three, or even many, are encountered in different parts of the organ. In these cases their size is generally in the inverse proportion to their number, so that, in some instances, instead of meeting with one large cyst, such as we have before alluded to, we encounter a number of little ones varying in size between a mustard seed and a hazel nut.\(^1\)

As an instance of multiple hydatids I may refer to a case recorded by Léveillé, and quoted by Davaine, in which many were found in the meninges and at the surface of the brain, in the corpus callosum, in the left middle cerebral lobe, in the right optic thalamus, and in other parts.

The increase in size of the hydatid being usually slow and gradual, little or no change is generally observed in the surrounding brain substance, which gradually atrophies under the pressure of the growing cyst. But occasionally congestion or softening does occur in the surrounding brain tissue, and more rarely still the presence of an hydatid in some portion of the brain seems to excite changes in the whole organ, and even in the cranium. Thus in the case of hydatid in the cerebellum, before alluded to, occurring in a man 24 years of age, the brain was found to be denser and firmer than usual, the ventricles distended with four ounces of clear fluid, and the skull-cap extremely thin, having a medium thickness of not more than about \(\frac{3}{16}\)", and at the squamous portions of the temporal bone being quite wafer-like, and not more than \(\frac{1}{30}\)" in thickness. In a remarkable case recorded by Dr. Barker (10):—"The calvaria was healthy but exceedingly thin, so as to be transparent in numerous places; the outer surface was natural, but the inner presented a series of shallow depressions, separated by angular ridges, evidently produced by the long-continued pressure of the subjacent convolutions, of which they presented an accurate mould. The surface also was congested, rough, and softer than natural. The base of the skull and its dura mater were healthy. There was no subarachnoid fluid, the convolutions being compressed against each other, and against the parietes, so as to obliterate the sulci; the surface was not congested. In the posterior lobe of the right cerebral hemisphere, was a hydatid cyst, occupying nearly the whole lobe, which was thus converted into a fluctuating cyst. It had rendered the lobe irregular and lobulated, and increased its dimensions; but the hydatid was covered everywhere by brain substance, although in many situations it was a mere film. The lobulated character seemed to have been produced by the superficial veins acting as ligatures. The cyst was single, about as large as a middling-sized orange, and contained two hydatids, one nearly as large as the cyst itself, the other the size of a walnut. They

\(^1\) In cases of multiple hydatids, their small size may be explained by the fatal nature of the malady, and the early death of the patient. The duration of the malady naturally varies according to the situation and number of the hydatids. Davaine records one case (loc. cit. p. 650) in which a large single cyst must have been 4 years old.
contained no secondary cysts; the brain in all other respects was healthy."

The hydatids met with in the brain are almost always barren, and thus correspond with the acephaloceysts of Laennec. Sometimes they are perfectly simple, but they may contain smaller secondary cysts in their interior, or bear them as buds on their exterior surface. The hydatids usually contain a clear, limpid fluid, and their walls are made up of the usual thin, homogeneous, concentric lamellae. In only two (12 and 23) out of thirty cases of which I have read the details, is any mention made of the hydatids containing echinococci or their remains. In these fertile cysts, in addition to the echinococci, the remains of the fibro-granular germinal membrane may be detected on the internal surface of the hydatid. Many cases of so-called hydatids in the brain are recorded by old writers, which have but a very doubtful right to this title. The word was formerly used with great laxity: everything in the shape of a cyst receiving this appellation—even the vesicles so common in the choroid plexus, which are now known to be simple serous cysts.

Hydatids in the brain seem to occur as often in the one sex as in the other. As regards time of life, they seem to be met with, in the great majority of cases, in individuals between the ages of 10 and 30 years. Thus out of 30 cases I have found the age stated in 24: of these 3 were below 10 years of age (5, 7, and 8 years), and 3 above 30 years (one "middle age," 37 and 38), whilst the remaining 18 were between the ages of 10 and 30 inclusive. This is very notable, and in striking contrast with what is known concerning the cysticercus and its tendency to occur rather in the latter half of life, than in younger individuals. We know so little concerning the mode in which the human body becomes infected with these cystic entozoa, that it is extremely difficult to explain such peculiarities. We do know, however, that the adult or fully developed condition of the echinococcus hydatid exists abundantly in the intestines of the dog, and perhaps we may also say that individuals between the ages of 10 and 20 years, have generally more to do with these animals than those of an earlier or more advanced age. This is a mere suggestion which, unfortunately, we are unable further to develop.

19. Silver and Lead.—In the 11th vol. of the Transactions of the Pathological Society an account is given by Mr. Sydney Jones of the post-mortem appearances in an old epileptic, who had for several years been in the habit of taking nitrate of silver as a remedy. "The choroid plexuses were remarkably dark: from their surface could be scraped a brownish black soot-like material; a similar substance was found lying quite free in the cavity of the fourth ventricle, apparently detached from the choroid plexus." A specimen of metallic silver was obtained from the plexus.

Lead has several times been detected by the aid of chemical analysis

\[1\] Several cases of hydatids in the membranes of the brain, of which I have read, have, however, been over this age.
in the brain, but for further details we must refer to the article on Lead Poisoning.

Prognosis.—In all cases when the presence of an actual growth within the cranium is diagnosed, the prognosis is very grave, but the degree of gravity depends upon the nature of the growth rather than upon the character or intensity of the special symptoms which it has occasioned. Thus, if there be reason to believe in the existence of carcinoma, the future prospects are as bad as they can be; if the conclusion be that syphilis is the cause of symptoms, there may be room for hope of complete recovery. Without entering upon a discussion of the general grounds of prognosis in the several cachexias which have been enumerated (p. 486), as the cause of tumour, it may be well to direct attention to a few points with regard to some of them.

If tubercle is believed to exist, the prognosis is highly unfavourable; but the course of tubercle en masse in the brain is sometimes exceedingly slow, and this is the case especially in children. The advance towards a fatal issue is to be apprehended when there is marked hectic, much elevation of temperature, and when the symptoms indicate the progressive invasion of different portions of the brain. On the other hand when—although there may be distinct paralysis, or amaurosis—the general health is tolerably good, and the symptoms have shown but little tendency to increase in either intensity or extent, there may be considerable prolongation of life.

The hypertrophy of the brain which is met with in children is slowly progressive, but its prognosis, under all rates of advance, is eminently unfavourable.

In syphilitic diseases of the brain or its meninges there is much room for hope; and it seems to be of little moment that the symptoms are varied and severe. Those which are the least amenable to treatment are the losses of sight and hearing, which not unfrequently exist; paralyses and spasmodic affections are often removed with considerable rapidity. The length of time during which the symptoms have lasted is a further guide in the prognosis, the hope of restoration being in inverse proportion to the duration of the morbid state. Still, unless the general condition be one of highly marked cachexia, amendment may be confidently expected. The presence of disease in the kidneys is of unfavourable omen, but even it often disappears under an antisyphilitic treatment. There are no cases which appear so bad and which recover so well as some examples of intracranial syphilis. Until the diagnosis of the constitutional state is established, the case may appear absolutely hopeless; sometimes the only missing link in the history may be unattainable because the patient is insensible, or in such a state of mental incapacity that no reliance can be placed on his assertions, but yet from such condition he may completely recover.

In the case of lead-poisoning the prognosis is favourable, provided that after a few applications of either the continuous current, or of
Faradisation, the muscles show some remnant of irritability. When the paralysis has existed for a number of years, and the wasting of muscular tissue is very great, it may be impossible to restore the limb, but yet, by continuous treatment, the advance of symptoms may be arrested.

In those cases where there is reason to suspect the existence of either aneurism, hydatids, or carcinoma, the prognosis is eminently unfavourable; but the forecast of a fatal termination is to be based upon the state of the general health of the patient, rather than of that of the special cerebral symptoms.

Under all conditions of Adventitious Product uncontrollable pain and vomiting are the most unfavourable symptoms; the former deprives the patient of rest, and the latter renders food useless, and often worse than useless, through the fatigue occasioned by its rejection.

Treatment.—There is nothing special which can be said with regard to the treatment of adventitious products in the head, for under all circumstances it is simply that of the different dyscrasias upon which they depend. The only remark which it seems to me desirable to make, is one in favour of the administration of large doses of iodide of potassium when there is a belief in the existence of syphilis. I have repeatedly seen the most menacing symptoms removed by the exhibition of K. I. in doses of forty grains, three and four times daily. When this has failed, recourse to mercury has proved curative, and with especial frequency when in conjunction with the baths and waters of Aix-la-Chapelle.

The pain of cerebral tumour may be palliated, and sometimes removed altogether by Indian hemp, and the application of ice.

Sickness is sometimes treated most successfully by absolute rest to the stomach, the patient being fed by nutritive enemata.

Convulsions may be checked by bromide of potassium, in doses of ten or twenty grains; but the powers of the therapeutic art are, with the exceptions above mentioned, inclosed within painfully narrow limits, and all that can be done is to palliate evils which cannot be removed.
ON APOPLEXY AND CEREBRAL HÆMORRHAGE.

BY J. HUGHLINGS JACKSON, M.D.*

The word Apoplexy has been used in two different senses; by some authors it has been employed to denote a group of symptoms, by others, an anatomical condition; according to the former Apoplexy means a sudden loss of consciousness, according to the latter an extravasation or hæmorrhage into the cerebral or other tissues. It is my purpose not to discuss the uses to which the word Apoplexy has been applied, but to describe the more important symptoms which are produced by effusion of blood in relation with nervous tissue.

I shall first state certain facts with which experience furnishes us as to—Positions of the clots, their Sizes, and the kind of Constitutional state with which Cerebral Hæmorrhage most often occurs.

Then I shall speak of certain symptoms of small importance which have yet great significance, as they may precede more severe hæmorrhages.

Next will come a brief consideration of the more striking symptoms, such as coma, insensibility, &c., which constitute, or occur in, the "apoplectic" state.

I shall then consider how far we can determine whether a comatose patient be suffering from clot or from some other cause of coma, (a) when there is no palsy to be made out, and (b) when there is decided hemiplegia. And, lastly, I shall speak of the course fatal and non-fatal cases run, to death, to permanent palsy, or to recovery.

Seat of Effusion.—(1) The blood may come from a vessel within a nervous organ, or (2) it may have arisen from rupture of a vessel outside the nervous masses.

(1). In cases of internal Cerebral Hæmorrhage the blood is nearly always effused into the motor tract, and into the highest divisions of it; viz. the corpus striatum or the thalamus opticus. As these higher divisions of the motor tract form the most vascular parts of the brain,

* I may be permitted to say that this article as it now stands is a condensation of one nearly twice the length, and that from it are omitted nearly all illustrative cases. I regret this mostly because it renders me unable to give due credit to those gentlemen at the London Hospital and elsewhere who have so generously helped me in procuring the materials from which this article is written. I can then merely acknowledge with my warmest thanks the help I have received from Dr. Woodman, Dr. Anthony Roberts, Mr. Steggal, Mr. George Mackenzie, Mr. Frederick Mackenzie, Mr. MacCarthy, Mr. Llewellyn, Mr. Gordon Brown and others.
they oftener suffer. For this reason paralysis generally occurs with Cerebral Hæmorrhage, and the paralysis is of parts on one side of the body, and is called Hemiplegia. Moreover, the corpus striatum and optic thalamus being the parts most frequently damaged, the hemiplegia from Cerebral Hæmorrhage is almost invariably the com-

* Dr. Broadbent in a remarkable and very valuable article (Med.-Chir. Rev., April 1866) endeavours to account for the gradual diminution of anaesthesia in lesion of the optic thalamus, and for the escape of the muscles acting bilaterally, in cases of the common form of hemiplegia.

It is then no part of my task to describe such symptoms as hemiplegia and loss of speech, as they have nothing specially to do with any particular kind of damage. In cases of hemiplegia, for instance, the damage may be of many other sorts than clot, viz. syphilis, and softening from plugging of the middle cerebral artery. It may occur with gross disease of the hemisphere which does not actually invade the motor tract itself, as abscess, hydatid cyst, tumours, &c. It comes on with disease of the surface of the brain as in unilateral meningitis after injury. Then it occurs after "epileptiform seizures," associated or not associated with gross organic disease; it is seen in chorea; it occurs in connexon with parturition. Most commonly it comes on quickly in a few seconds or minutes, but now and then, as when from tumour, very slowly. It occurs at any age whatever. It may last a few hours or for life. It varies in degree from numbness to total inability to move. The presence of deviation of the eyes and head does not help to declare the nature of the lesion, nor do these symptoms help us to determine, when we are certain of hemorrhage, whether the blood be inside or outside the brain. So then it is plain enough that the loss of power in a certain muscular region, by itself, says nothing of the nature of the internal lesion, but the condition of the muscles tells us something, as will be elsewhere remarked. Yet after all, when assisted by facts as to age, state of system, loss of consciousness, &c., hemiplegia has very great value in the "apoplectic state."
twitches; these abnormal contractions displace for a while, or till death, the immobile condition which set in at first. There may be a distinct convulsion which shall affect one side solely, or one side much more than the other; continued rigidity soon after a seizure points frequently to haemorrhage over one hemisphere, but it may occur with local softening. The eyes and head which have deviated from the side affected, will turn to that side when rigidity or spasm sets in. Occasionally one side is paralysed and rigid, and the other, including the head and eyes, is subject to frequent clonic spasms. It may be well to remark that when in deep coma from Cerebral Haemorrhage there is twitching of one side, we are not to conclude that the chief damage is on the opposite side of the brain. The clot after destroying, let us say, the right corpus striatum, may, having opened the ventricle, be lying in part on the bodies in the floor of the left lateral ventricle.

It is with this sort of paralysis that defects of speech occur, as the lesion then nearly always, besides involving part of the [left] corpus striatum, extends to or actually destroys the grey matter of certain convolutions near this motor centre. M. Broca thinks the disease usually involves the hinder part of the third [left] frontal convolution, and there is no doubt but that it is nearly always—always in my experience—in this region.

These two ganglia may be broken up more or less from a lesion the size of a pea to almost a complete washing away of them. The clot may burst on one side into the lateral ventricle, or, what is rarer, may break through the island of Reil into the Sylvian fissure. Either of these two events is necessarily fatal, the patient rapidly dying in very deep coma. In these cases it is important to bear in mind that there is often no distinct hemiplegia, and sometimes there are no other local symptoms to indicate where the clot lies.

Occasionally the blood is confined to one of the two bodies above named, and now and then their line of junction runs through the middle of a clot. Sometimes the greater part of both is ploughed up, and we may find that the clot extends into the crus cerebri as well. Occasionally we see a large clot outside the corpus striatum and thalamus tilting these bodies towards the other side—the convolutions being split off almost as if cut from them, the blood thus making a gap for itself.

The degree of paralysis is in proportion to not so much the size of the clot as to the extent of the motor tract it destroys. If a large clot lie outside the ventricular part of the motor tract, the palsy may pass off sooner than if a smaller one damages the intra-ventricular part of the corpus striatum. Recovery from hemiplegia may occur when part of the motor tract is actually destroyed.

A clot cavity is often very irregular, e.g. it will begin in the thalamus and slant downwards to the insula, so as to come close to the grey matter of the convolutions, leaving most of the corpus striatum uninjured; or it will begin in the corpus striatum and slant
downwards in the lower part of the thalamus, and may thence extend into the crus cerebri. It is, indeed, very seldom that a clot, big enough to have caused continued hemiplegia, is strictly limited to either the corpus striatum or the thalamus opticus. It is very important that a careful description should be attempted, in those cases at least where there has been defect of speech. Turner's recently published paper on the Convolutions of the Cerebrum will be a very great help in these investigations. A clot in the hemisphere rarely rises above the level of the ventricle.

Sometimes we find that a clot is quite confined to the crus cerebri, but this is very rare, and I have never seen an instance. Damage to the crus cerebri causes hemiplegia on the opposite side, and if the under and inner part of the crus be involved, the third nerve is paralysed on the side opposite the paralysis of the limbs. An important case of this kind has been published by Dr. Herman Weber, in the Medical and Chirurgical Society's Transactions, vol. xlvi.

So far the two sides of the motor tract are distinct, and it is a rare thing to find a recent clot on each side of the brain. It is not at all rare to find two clots, or rather clot-cavities, of different dates, one on each side of the brain.

At the pons, the two motor tracts are welded together; we have therefore, in hemorrhage into this part of the nervous system, usually paralysis on both sides of the body, for the escaped blood is seldom limited to one side of the pons. The blood is generally effused in large quantity, generally produces deep insensibility, universal powerlessness, with minutely contracted pupils, and then usually kills in a few hours. Thus hemiplegia from disease of the pons is rare, and when it occurs it is of a different kind from that to which disease of the crus cerebri, thalamus opticus, or corpus striatum gives rise. But the palsy, even although general, may be more marked on one side, and then we may diagnose the seat of the clot. In disease limited to one side of the pons we usually have paralysis of the fifth or sixth or seventh nerves, or of two of them or of the whole of these nerves on the side opposite the paralysis of the limbs. The pupil is sometimes, not always, minutely contracted on the same side as the lesion of the pons. However, I have not myself seen distinct hémiplégie alterne in a comatose patient.

I have, however, seen in the practice of Dr. Brown-Séquard, a patient who, it appeared certain, had escaped with life from the effects of a clot, which had paralysed both sides of his face as well as all four limbs. Very often the blood bursts into the fourth ventricle, or it may extend into the crura cerebri or crura cerebelli.

Of effusion of blood, limited to the medulla oblongata, little is known. I have made but one autopsy on a patient who had had effusion limited to this division of the nervous system. This patient had recovered from an attack of hemiplegia, due, as we afterwards found, to a clot in his right thalamus opticus, when all at once he lost speech from paralysis of his tongue. A few years later the patient
died, and Dr. Lockhart Clarke, to whom I gave the patient's medulla oblongata, found in it remains of past effusion of blood. Paralysis of the tongue, paralysis of one vocal cord, difficulty of swallowing, and deafness, are the symptoms which indicate damage to this part of the nervous system, and the damage is sometimes by clot.

Large and fatal effusions of blood limited to the hemisphere above the level of the corpus striatum or thalamus opticus, or to one lobe of the cerebellum, are very rare, except from injuries; in the latter cases the clot reaches the surface, and indeed is often rather a pulp of brain and blood than a distinct clot. Whenever a clot is found close to the surface, especially if the convolutions be bruised, and if there are small specks of blood round the principal clot, above all, if distant from the principal lesion there are little specks of blood round about pulpy patches of brain, an injury has probably been received.

We occasionally see the remains of small clots, but seldom large ones, in the cerebral and cerebellar hemispheres of patients who have died of non-cerebral disease. It is most important to bear in mind, especially when we are thinking of the "localization of faculties," that the cerebral hemisphere is rarely solely the seat of extensive disease of any kind. The motor tract is nearly always affected too. Clots starting in the bodies in the floor of the lateral ventricles, and breaking or pushing their way towards the surface of the hemisphere, are very common, and of these I have spoken. Yet a clot, or indeed any disease limited to the cerebral hemisphere, above the level of the ventricle, need not reveal itself by very definite symptoms, such as hemiplegia or loss of speech. Thus a man may present no symptoms when he has a large abscess in one cerebral hemisphere. Haemorrhage in the cerebellum is very rare, and it is very difficult to diagnose it. I have not yet seen an instance. Sometimes there is hemiplegia, and sometimes there is not. One mark is vomiting, but this also occurs in haemorrhage in other parts of the brain, but probably not to so great an extent. Dr. Broadbent has recorded two very important cases in the Transactions of the Pathological Society.

There are cases in which we find blood in the lateral ventricles, when the ganglia in their floors are intact. I have mentioned two cases in the article on "Convulsions." In one I discovered that an aneurism of an artery at the base of the brain had burst into the third ventricle.

Sometimes two or more large recent clots are found in different parts of the brain. My friend Mr. Llewellyn showed me a specimen from a case in which there was a clot arising in the floor of the lateral ventricle, and another of the same date in the pons. Dr. John W. Ogle, (Path. Soc. Trans. vol. xv. p. 8) has recorded a case in which there were three recent clots, one in the right corpus striatum, one in the left thalamus opticus, and one in the pons Varolii. Dr. Bäumler has supplied me with notes of a case of a man, thirty-four years of age, who died three hours after a fit, in whose brain three recent clots were found; a large one in the centre of the right hemisphere, a small one
in each of the optic thalami, a small one in the right crus cerebri. The ventricle was full of blood too. In this case there was a remarkable variation in the sizes of the pupils. The point of interest, when each motor tract is much injured, is the verification or otherwise of Dr. Broadbent's hypothesis, as to unilateral and bilateral movement. When we are called to a patient who is hemiplegic, say of the left side, it is very important to inquire if he have had hemiplegia on the other side before or not, as the right side of his brain may remain much damaged when the left hemiplegia has disappeared. When both sides of the brain are damaged, we sometimes find symptoms beyond those of hemiplegia on both sides, such as difficulty in swallowing, as Dr. Broadbent's hypothesis of it would lead us to expect. After discovering the main clot, we should carefully search the rest of the brain, especially the pons and medulla, for small effusions, often only little specks.

2. Blood outside the brain is found in three positions. (a) In the pia mater under the arachnoid, (b) in the cavity of the arachnoid, (c) and betwixt the dura mater and the bone. When the clot is found between the dura mater and the bone, we may be nearly always sure that it is the result of injury. Usually it comes from a laceration of the middle meningeal artery, but Abercrombie quotes a case recorded by an American writer, in which this vessel was opened in connexion with caries of the parietal bone. When the blood is in the arachnoid cavity it is again very often the result of injury. Prescott Hewett says that extravasations of blood here are very common, and much more so than is usually supposed. He adds that the injury causing such an effusion is often a trifling one, and that the effusion may occur without any apparent lesion of the brain or membranes. This form of intracranial hemorrhage is of medico-legal interest, as it may occur after a fall thought little of, especially if the patient were drunk when he fell, or if he had a fit. Indeed, it has occurred to me on two occasions lately to find blood in the arachnoid cavity in two patients who, not many hours before their death, were supposed to be only drunk. When the blood is in the meshes of the pia mater (and perhaps above the arachnoid as well) it may have come from (a) rupture or bruise of the brain, or as Mr. Hutchinson pointed out to me in a case of fall on the head producing fractured base, presumably from rent of the carotid artery, (b) from bursting of an aneurism of a large cerebral blood-vessel, or (c) from "spontaneous" giving way of a vessel in the pia mater without any sign of injury to the brain or its membranes. The existence of blood in this position should lead us to a most careful search for (a) bruises or pulpings of the brain, for rents of the membranes and for fissures of the base of the skull; (b) to a laborious search for aneurism, and (c) to a critical consideration of the state of the blood vessels, the heart and kidneys. Aneurisms of the larger cerebral blood vessels are said to be rare, but Dr. Gull thinks they are not often met with, simply because they are not often looked for. "Whenever," Dr. Gull says, "young persons die with symptoms
of ingravescent apoplexy, and after death large effusion of blood is found, especially if the effusion be over the surface of the brain, in the meshes of the pia mater, the presence of an aneurism is probable."

**Size of the Effusion.**—This varies from several ounces to a few drops. I never saw so little as a few drops where there was effusion in one place only in a fatal case. But we frequently find a little cavity, the size of two peas or more in the intra-ventricular part of the corpus striatum, and even when there has been no palsy for some time before death. In the case of effusion into the medulla oblongata already mentioned, p. 508, the blood was confined to a very narrow region, and must have amounted to a few drops only. Small clots demand most careful consideration. We have, unfortunately, very little precise information about the symptoms they produce, as they do not cause death. From the necessity of obtaining proof of statements which only post-mortem examination can supply, we are obliged to study the subject of Cerebral Hæmorrhage, rather from the basis supplied by cases in which the effusion has been big enough to kill, than from the wider one of "effusion of blood in nervous tissue," and thus our studies, even of the phenomena which effusion of blood produces, are one-sided. There is, for instance, a great deal of evidence as to the results of the escape of a large quantity of blood into the corpus striatum, but there is very little evidence as to the symptoms which the escape of a minute quantity in this body produces, and scarcely any evidence as to the results of trifling hæmorrhage into the hemisphere or medulla oblongata. We not unfrequently find at autopsies small clots in the brain, but we very rarely get any good history of past cerebral symptoms to connect with them. I think it most likely that sudden, although small effusions, may be the cause of slight attacks of a vague kind, such as unilateral numbness, giddiness, a day's stupor, &c. In some cases—as in that of a patient sent to me by Mr. F. M. Corner—of suddenly occurring defect of sight, giddiness, tingling in the ears, tingling of the fingers and toes, more of one side, we see hæmorrhages in the retina to account for defect of sight, and it seems warrantable to infer that the other symptoms are due to small clots in the brain. The supposition will be all the stronger, when, as in the case alluded to, there is albuminuria, inelasticity of the arteries, &c.

I now come to the consideration of the *Sort of Constitution patients have who suffer from Cerebral Hæmorrhage.* There can be no question that even fatal Cerebral Hæmorrhage occurs in people who have been well, at least in the conventional meaning of the word. Of the apoplectic patients whom I see at the London Hospital, some have been taken ill at their work, or whilst going about in the streets. People in the lower ranks of life, however, are obliged to work through much ill-health, and some of them are decidedly unsound. Of course, when a vessel breaks in the corpus striatum of a man at his work, in apparently full vigour, however healthy his organs may appear to be, even at the autopsy,
we should not believe him to have been sound, were the microscope itself—a very unlikely thing—to reveal no change in his cerebral vessels. In cases of this sort the haemorrhage may be due to rupture of a very small aneurism within some nervous organ, and then the case is pathologically like those in which there is meningeal haemorrhage from rupture of an aneurism of a large arterial trunk like the basilar or middle cerebral. Dr. Bristowe has drawn attention to rupture of small internal aneurisms as causes of Cerebral Hæmorrhage, and Dr. Bouchard has recently written a most important monograph on small aneurisms leading to Cerebral Hæmorrhage in old people.

But in many the hæmorrhage is clearly but a sign of a bad constitutional state, or rather evidence of local failure in an unsound habit of body. From this point of view hæmorrhages in the nose, in the retina, or in the pons, are all equally significant, although the symptoms they produce differ most widely in importance. The practical point is why the blood-vessels of the nervous system break anywhere? They are more or less unsound, and their unsoundness is a part of a general bodily unsoundness.

It has long been known, thanks to Bright, Johnson, Kirkes, &c., that diseased arteries occur in association with granular disease of the kidney and hypertrophy of the left ventricle of the heart. The changes are wider than these, the patients have usually emphysematous lungs, and they more rarely have cirrhosis of the liver. But it will be convenient to limit ourselves to the changes which make themselves most obvious during life. The following view is, I believe, a fair representation of what is generally believed as to their bearing on effusion of blood in the brain. A diseased kidney induces impurity of the blood, and impure blood has a difficulty in passing the capillaries; there is compensatory hypertrophy of the left cardiac ventricle to compel it forward. The larger vessels and capillaries themselves are diseased too, perhaps as one piece of general bodily degeneration, of which the state of the kidney is another. So the bad blood is forced, by a strong ventricle, on the capillaries unwilling to receive it, and the over-distended arteries, being inelastic, now and then burst. Whatever the explanation may be, there is no doubt of the frequent association of hypertrophy of the left ventricle of the heart, granular disease of the kidney, and Cerebral Hæmorrhage.

In thinking of the warnings of Cerebral Hæmorrhage,* we usually call to mind some symptoms, such for instance as a little facial palsy, which show that a slight bleeding has presumably happened. When blood has actually got out into nervous matter we can do little to help

* We hear the term Premonitory Symptoms of Cerebral Hæmorrhage used in three senses. (1.) The state of the system before any escape of blood has happened. (2.) Certain local symptoms which are, indeed, themselves often due to little haemorrhages. (3.) The symptoms which point to an immediate outbreak of a fatal haemorrhage, and which symptoms are doubtless often signs of the beginning of that haemorrhage. Each of these has, from a utilitarian point of view, a distinct value. The first is now being considered. The third will be spoken of in connexion with the circumstances which attend the setting in of severe Cerebral Hæmorrhage.
the patient, although the symptoms which small effusions produce may quickly pass off by themselves. So the best warnings are those which the patient's tissues supply, and these are the impulse and apex beat of the heart, mobility, tortuosity, and hardness of the arteries and the chemical and microscopical examination of the urine. The basis supplied by an estimation of the patient's general vital status should be our point of departure in forming a prognosis, and without a reference to such a basis, the local symptoms he comes to us for will have a very indefinite meaning and often no meaning, for practical purposes. Unfortunately, however, patients do not consult us for slow changes in tissues, but for sudden disorders or losses of function due to damages of particular organs, such, for instance, as hemiplegia. It is remarkable how long bad organs will keep one another in countenance when they descend together in vitality. Thus it is not at all rare for large Cerebral Hæmorrhage to happen to those who have the appearance of health, but who have degenerated retinae, "calcareous" arteries, very small granular kidneys, and hypertrophy of the left ventricle. A brewer's servant, forty years of age, died under my care in uremic coma, about fifty days after an attack of hemiplegia, due to large effusion of blood outside the bodies seen in the right lateral ventricle. Now, although this man was most unsound—kidneys granular, heart hypertrophied, arteries rigid, and retinae in an extreme state of degeneration—he "felt quite well" until one unlucky morning when, as he was entering a stable, his left leg failed and he became unconscious. He seemed to wonder why the accident befell him. A year before he had had dropsy. Sometimes however a patient consults us for slighter non-cerebral symptoms, and then we have the chance of considering the full possibilities of failure which the bad state of his system may imply. Thus, a girl only nineteen years of age, who died under my care with large Cerebral Hæmorrhage, had been ill three months before the attack, with symptoms, so far as the mother could tell me, of the vaguest import, e.g. malaise, ill temper and general weakness. Yet this girl's larger cerebral arteries were rigid and calcareous, the left ventricle of the heart was monstrously hypertrophied, the kidneys very small and granular, and her retinae—in which the opthalmoscope detected clots—were extremely degenerated. Her first striking cerebral symptom was the one produced by the large clot in the brain which in seven days killed her. Had I seen this girl when she was going about—let us say a fortnight before she died—probably her complaints would have seemed very indefinite, and would not have pointed to Cerebral Hæmorrhage. But the condition of her tissues would have spoken clearly enough. Much is said of the apoplectic habit, but the only bad habit of body which I would venture to declare apoplectic (i.e. in the sense of the word implying a liability to Cerebral Hæmorrhage) is the one of which granular kidney is part. Of course this constitutional state does not point only to failure by breaking of a blood vessel in the brain. Patients who have granular kidneys are liable to very many diseases
in the nosological table. And when they have suffered severe Cerebral Hæmorrhage they may die of something else. In the girl's case just mentioned, the peritoneum showed signs of recent inflammation. Mr. Corner's patient (see p. 510) died of pericarditis, another woman who was hemiplegic from a small clot in one corpus striatum, died also with pericarditis; the brewer's servant went off by uremia.

Since rupture of vessels is but one of the many things to which patients who are so unsound are liable, when trying to forecast the future of a patient who has already suffered hæmorrhage in his nervous tissue, we predict not so much from the importance of the symptom, let us say a day's thickness of speech, or a month's complete hemiplegia, as from the condition of his system which has allowed so significant a sign of failure. So if a patient has retinal hæmorrhage—I take this instance as we can see the blood—he may die of effusion of blood in his pons, or of pericarditis, or of uremia, and in many different ways. And speaking generally it is better even to underrate the striking physiological phenomena (as for instance so remarkable an occurrence as loss of speech), than to underrate the signs of widespread conditions of ill-health.

It is a thing of extreme rarity to find healthy kidneys, and a non-hypertrophied left ventricle (excluding, as regards the heart, those long bed-ridden) at autopsies on patients who have died soon or late after Cerebral Hæmorrhage; still a patient may suffer Cerebral Hæmorrhage and yet have healthy kidneys, and arteries but slightly, if at all, diseased. Yet I feel sure that when we see a man of middle age hemiplegic, and find his tissues fairly sound,—no albuminuria, soft arteries, heart normal,—we cannot tell whether his palsy be due to softening or to clot, although we say if there were no loss of consciousness when the attack came on, it was, there being no signs of degeneration, probably owing to softening.

_Slight "warning" Symptoms._—I will now speak of some of the slight symptoms from effusion of blood into the brain. Two of these are visible hæmorrhages, viz. epistaxis and clots in the retina. These two warnings are quite as significant as the facial palsy I more particularly describe, but the first is obvious, and the second will be considered elsewhere.

The commonest cause of paralysis of the face is disease of the trunk of the portio dura nerve, but the facial palsy which warns us of coming severe Cerebral Hæmorrhage is not of that kind. It is simply a little drawing of the face to one side without any palsy of the orbicularis palpebrarum. This kind of facial paralysis is described by Trousseau in the first lecture in the translation of his lectures by my late friend and colleague Dr. Bazire. This limited facial palsy is, indeed, part of an attack of hemiplegia. If then a patient consult us for a little drawing of the face we think it a far more unfavourable omen than if he came for decided paralysis of the whole muscular region which the facial nerve supplies. Palsy so partial is always a bad sign, but if with this symptom there be retinal degeneration, rigid
arteries, hypertrophy of the left ventricle, albumen and casts in the urine, the patient is in imminent danger, although he may feel well enough to go on with his work. His pathological condition shows that he is ready to fail in many ways, and the partial paralysis declares that a slight failure has actually occurred deep in his nervous system. When such a trifling amount of damage has been repaired our anxiety is not appreciably diminished.

Usually there is some defect of speech with the above-mentioned facial palsy. Sometimes its occurrence is very striking and dramatic, and it may be immediately followed by more or less hemiplegia, or after a few hours by coma and death. But just now I speak of slighter symptoms passing off within one or two days. Now I really think that such slight paralytic symptoms are of worse omen than complete hemiplegia is. Of course I mean that they are of worse omen in themselves, for the full significance of this class of symptoms can only be determined from the evidence of the general condition given by examinations of the urine, heart, &c. Epistaxis in a patient who has wide degenerative changes is of worse omen as regards life, than loss of speech in a patient whose heart, arteries, and kidneys are healthy. I think, too, that the slighter symptoms, retinal haemorrhage, partial facial palsy, &c. occur more often in patients who are widely unsound. But on the whole it is very generally true that suddenly-occurring defects of talking in people past forty are to be taken as very bad signs, whether they seem to depend on disease in or near to one corpus striatum—and then there is no difficulty in swallowing—or whether they arise from disease near the medulla oblongata, and then there is usually a difficulty in swallowing. As a rule, unilateral symptoms attend the defect of speech, but the limb defects may occur alone. Suddenly-occurring numbness limited to the face, arm, and leg on one side, must I think point to something wrong on the opposite side of the brain, although that something may be inappreciable post-mortem. When occurring in a patient past forty it should give us considerable anxiety, and at any age it should lead to a careful examination of the heart, arteries, retina, and urine.

Of course blood coming from the nose, sudden defect of sight, difficulty of talking, or of swallowing, or sudden unilateral numbness, have not always the ill meaning implied in the foregoing remarks. After the age of forty they point at least frequently to the fact that the patient will be liable to be incapacitated or to be killed by a larger hemorrhage. I say liable, as a man so unsound as some of these patients are, may die in many ways. And it is from considerations supplied by the constitutional state that a symptom obtains its proper value, and not from its own slightness, or from its very temporary stay. Under that age, and indeed at all ages, the possibility that the paralytic symptoms depend on the unknown changes which exist with seizures classed as epileptiform, must be considered. Sudden and temporary loss of speech, loss or defect of sight, occur with or without one-sided paralytic symptoms in patients who are liable to have
chronic convulsive seizures called epileptiform. There are usually, however, circumstances, such as cramp, or more or less convulsion when the temporary local defect comes on, which declare the true nature of the case. Then the defect of speech which precedes large haemorrhage is rather a difficulty in talking than a temporary inability to talk at all. A frequent mistake of words does not seem to me to be so serious a symptom. Although I have known it in one case follow a temporary attack of hemiplegia, and precede fatal “apoplexy,” I attach less importance to it than to thickness of speech. Any one who looks out for mistakes in words will meet with them occasionally in the conversation of most people.

If the system were healthy, if the symptoms were not found out on waking in the morning, especially if the patient were young, we should think they were most likely due to the unknown changes in the nervous system of epilepsy, or at least not to effusion of blood. In Cerebral Hæmorrhage we find there is a succession of symptoms; but they are usually different. An epileptic has frequently something wrong—numbness, deadness, or cramp of the same hand or the same foot. But he loses his speech or sight for a while, in the same way many times. Besides, the symptoms are usually paroxysmal, beginning and ending suddenly. There are, however, cases of temporary loss of speech, to account for which it is impossible to frame anything like a satisfactory hypothesis.

Syphilised patients also are liable to a succession of different nervous symptoms. But in these cases the symptoms are more marked. They are usually defects of nerve trunks; in Cerebral Hæmorrhage, central parts, as the retinae, corpus striatum, lingual nucleus, &c., are damaged. For instance, there may be from syphilis complete paralysis of one or more ocular nerve, or of the facial nerve, or perhaps of one of the nerves to the hand; next, difficulty in swallowing, or aphonia, then indefinite epileptiform seizures, then hemiplegia, &c.

There are innumerable other symptoms showing failure of the nervous system, such as giddiness, want of sleep, and drowsiness, irritability of temper, and defect of memory. A page might be filled with the symptoms which precede “apoplexy.” But most of them, even if they point to failure of the nervous system, do not point with any special insistency to Cerebral Hæmorrhage. When a patient of middle age consults us for vertigo, drowsiness, or for defect of memory, we must of course think of Cerebral Hæmorrhage as one of the possibilities, but we cannot even say it is the most probable of many possibilities. Severe pain in the head is not—excluding cerebral aneurism,—a common forerunner of Cerebral Hæmorrhage. If severe pain in the head for days, weeks, or months, precedes a convulsion, followed by coma and partial hemiplegia, it is, if there be no albuminaria, more likely that there is organic disease in the head other than Cerebral Hæmorrhage. It is almost certainly not hæmorrhage if the patient be young. Yet now and then intense pain in the head precedes Cerebral Hæmorrhage for weeks, and is sometimes accompanied by vomiting.
In the cases of this kind that I can call to mind, there has been extreme granular disease of the kidneys.

_Age._—Something must now be said of the age at which Cerebral Hæmorrhage is most likely to happen. We know from a consideration of many cases of patients who have died of Cerebral Hæmorrhage, that effusion of blood in nervous tissue is an uncommon event in young people. Of course cases are excepted where blood is effused on the surface of the brain after an injury, and I exclude hæmorrhage in the cavity of the arachnoid which occurs in very young children. And it is not so much that escapes of blood are rare events in young people, as that a certain bad state of constitution which leads to it is not often arrived at early in life. We must not, however, trust to such a generality. For the relation of symptoms is to changes in tissues and not to years of life. Cerebral Hæmorrhage of a kind just like that occurring so frequently in people past forty occasionally happens in people about twenty, who have chronic Bright's disease. Now taking in cases of rupture of cerebral aneurisms I feel sure that we shall make mistakes if we trust much to generalities about age, when we are called to a patient who is insensible. Such generalities will serve us in helping to a conclusion, but to declare a severe convulsion followed by deep coma to be "merely an epileptic fit," from which the patient will recover simply because he is young, is to trust to a principle which will most often lead us wrong. Nor if we are called to a person hemiplegic, the nature of the lesion producing the attack being unknown, must we think because he is old that he will not recover. I have seen a man eighty-four who had recovered from hemiplegia. Then, on the contrary, we see not very unfrequently hemiplegic men and women whose paralysis occurred in early childhood.

I now come to speak of the more decided and more striking symptoms which are produced by large Cerebral Hæmorrhages—of those symptoms which occur in the "Apoplectic State," and which may or may not indicate Cerebral Hæmorrhage.

_Coma, Insensibility and Confusion of Mind._—I think it impossible to describe a condition which is characteristic of Cerebral Hæmorrhage. Blood gets out of its place into nervous matter, and about nervous masses, in places so different, to such varying amounts, under such different circumstances, and in people whose constitutional states vary so widely, that we have even difficulty in fixing on commonly-occurring severe cases to serve as convenient clinical standards of the apoplectic condition.

A person who is suffering from the effects of the escape of blood into his brain, may be only confused for a few moments, he may be insensible for a few hours or days, or he may pass hurriedly into deep coma and die in half an hour. The coma may come on with a convulsion, or without one. He may die so rapidly that it is difficult to get to know how he died. Convulsions may occur in coma after the attack, or they may not. Nor do we find that such a well-known symptom as stertor is of diagnostic value beyond this, that it is a sign
of deep coma, and Cerebral Hæmorrhage is the commonest cause of deep coma. It occurs sometimes in alcohol poisoning, or in poisoning by prussic acid; and we often find it absent, in people who die from Cerebral Hæmorrhage, at all stages of their insensibility.

Let me mention a few cases of coma not following convulsion, in each of which there was a large clot in the brain.

(a) The patient lies profoundly insensible, with stertorous breathing, dark face, full veins, rapid irregular pulse, and with occasional stoppages of respiration for ten seconds, more or less.

(b) The patient seems to be, except from his awkward position, as if in a gentle sleep, pulse seventy-two, respirations quiet and fourteen.

(c) He is quiet, but now and then he uses his arm to rub his eyes, or he may resist a stethoscopic examination, or grunt, or swear; all the while taking no notice of questions asked in voices familiar to him.

(d) The patient is so far conscious as to be able to put out his tongue when urged, but quickly relapses into a state of stupor.

(e) He does many things we ask him to do in a dazed manner, staring at us and looking about as if wondering where he was.

(g) It is believed there may be considerable Cerebral Hæmorrhage without a trace of insensibility.

Although, as facts show, there is a vast difference in the degree of insensibility in different cases, the point is one of considerable diagnostic importance, and especially when there is doubt whether coma after convulsions depends on clot, or on the unknown state of the nervous system which attends those convulsions which are generally called epileptic or epileptiform seizures. When the coma is slight, especially if it do not deepen, if the patient be young, the great probability is that there is no clot. But we shall get wrong now and then, if we base the diagnosis on any such generalities, as cases in the article on Convulsions illustrate. It is said too, that if we can rouse a patient from a state of insensibility, we may, in a doubtful case, determine against Cerebral Hæmorrhage in favour of a slighter cause, i.e. Drunkenness. If we rouse him so that he makes intelligent replies, or gives his name and address, the test has very great value, but not if we merely get him to grunt out an oath or a few irrelevant words. Besides, we find sometimes that people who are very drunk cannot be roused to speak. The test will help our diagnosis in the early stage of opium poisoning also, and when it may not lead us to a decided diagnosis, it may determine the immediate use of the stomach pump.

The symptoms furnished by alterations of the pulse and respiration are of great importance, but they are of more value in prognosis than in diagnosis. It is not possible to describe a kind of pulse which is, I will not say characteristic, but even of much value in the diagnosis of cases of Cerebral Hæmorrhage. The pulse is often described as full and laboured. The fulness is certainly no sign of vigour. The full pulse I have found in a case of meningeal hæmorrhage, which came on
in a young man, who when the seizure occurred was lying in bed pale
and exhausted from profuse epistaxis. The full apoplectic pulse does
not declare that the case is one of "sanguineous" apoplexy, as distin-
guished from "nervous" apoplexy. Much of the fulness is due, I
suppose, to the degeneration of the artery. The rate of the pulse
is of more importance.

Very much, however, depends on the time which has elapsed since
the attack came on. Soon and late are to be defined according to
the general symptoms. Half-an-hour is late when blood breaks into
the ventricle, but very early when the blood effused into the brain is
well walled in.

A patient may have a large clot in his brain, as in a case already
alluded to, and yet his respiration and circulation may be quite
normal, e.g. the former seventy-two and the latter fourteen in the minute.
Indeed, he may seem to be lying as if lazily inactive, or, but for his
awkward position, quietly asleep, and yet die a few hours later; in the
case I am thinking of, in five hours; and a large quantity, e.g. several
ounces, of clot may be found in his brain. So that whilst the greater the
abnormality of the respiration and circulation, the worse is the progno-
sis, it is an error to suppose, as the case just alluded to indicates, when
the respiration and pulse are natural, that the patient may not soon die.
For after an hour or two, or a day or two,—I cannot speak more
definitely,—the respiration may become quick, the pulse rapid, and be
now and then, or even constantly irregular. These symptoms occurring
soon—e.g. in two or three hours,—are far worse signs than any depth
of coma. Nay, if the pulse become irregular, the partial restoration of
the patient to consciousness does not encourage us much, for he may
be advancing to death at a time when his mind is becoming a little
clearer. If the pulse be very abnormal in any way, e.g. 60 or 150,
the prognosis is unfavourable, and it is all the worse, if after being
slow, it becomes very quick. Irregularity of pulse is a worse sign
still, about the worst that can present itself, in suddenly occurring
coma, except perhaps irregularity of respiration. An exceedingly slow
rate of respiration, e.g. three or four in a minute, I think, shows that
death is at hand. If the pulse beats hastily and then very slowly, or
stops for a few seconds, a fatal issue may be expected.

I have less faith than I find is common in the diagnostic value of
abnormal conditions of the pupils in sudden lesions of the nervous
system. I shall speak of the significance of great contraction of the
pupils, when I come to the diagnosis of opium poison from effusion of
blood into the pons varolii. There seems to be an impression that
when a man is comatose his pupils must be either "contracted" or
"dilated." Now extreme contraction or extreme dilatation of the
pupil are rare symptoms.

It is quite certain that there may be a large clot on one side of the
brain when the pupils cannot be considered to be abnormal.

Dr. Wilks says that * "we cannot connect the conditions of the pupils

* Guy's Hospital Reports, 1866, p. 177.
with any definite lesion, for their state is very variable, and is liable to be influenced by very slight causes." Speaking of the contraction observed in disease of the pons, he adds, "just as we see this [contraction of the pupils] produced by effusion of blood at the base or into the ventricle." Now more importance should be attached to differences in the sizes of the pupils, but only when the difference is very great. For the pupils are often of different sizes in healthy people. Were one pupil very minutely contracted, and the other presumably unaltered, the contraction would point to disease on one side of the pons Varolii. But I have not seen minute contraction of the pupil on one side from clot in the pons when there has been coma. I have seen it in two cases of hemiplegia presumably from clot in one side of the pons. Were one pupil very widely dilated, it would lead me to search most carefully for signs of injury to the head, as Mr. Hutchinson has found very wide dilatation of one pupil in cases of blood effused from fractured base under the dura mater in the sphenoidal fossa, the dilatation being on the side of the effusion.

Fixedness of the pupil is the worst sign the eye furnishes, if the pupil be very wide. It should be carefully estimated, and the best way is to throw light into its centre by the ophthalmoscope.

In severe convulsive seizures, the pupil will dilate widely, but this is not always the case. Moreover it is well to say, that some people in apparent health have pupils so small that they could not be obviously smaller by disease.

We come now to the diagnosis of what is wrong with a patient who is comatose, and who may or may not have Cerebral Hæmorrhage. This is a most difficult matter. It is comparatively easy to say from tabulation of a large number of cases that such and such symptoms were present in Cerebral Hæmorrhage. But it is not unfrequently impossible to tell what is the matter with a patient who is found comatose, convulsed, or hemiplegic. In the present state of our knowledge the symptoms observed in cases of Cerebral Hæmorrhage are not characteristic of Cerebral Hæmorrhage.

We may be called to a patient who is dead before we arrive at the place where he lies. Although then there are no medical difficulties, in the narrow sense of the word medical, we have sometimes very painful anxieties as to the cause of the rapid death, especially when the patient was just before the seizure in apparently good health—and occasionally difficulty in deciding whether the death was the result of violence, poison, or disease.

I have often heard it said that death does not occur very suddenly from Cerebral Hæmorrhage. But death will certainly follow in a few minutes, although the instances are rare.

A woman was visiting her sister, and suddenly when at the tea-table stopped in the midst of a laugh, and cried out, "Oh, my head," and fell back in her chair and died sitting, within five minutes at the most. So far as I could learn there was no obvious convulsion, but the patient may have died in the first stage of one.
(For the opportunity of seeing this patient I am indebted to Dr. Anthony Roberts.) We found much blood effused under the arachnoid, most at the base, where there was a very large clotted mass, but we did not discover cerebral aneurism. There was blood under the spinal arachnoid also, chiefly in the dorsal region. The kidneys were slightly granular. The suddenness of effusion was presumably the chief cause of the rapidly fatal result. For we see more blood effused than was found in the head of Dr. Roberts' patient, in people found comatose and who live some hours.

One might, from theoretical considerations, imagine that effusion of blood in or near the medulla oblongata would kill instantly. I have not yet seen such a case. I have known a woman live in deep coma some hours, although at the autopsy her pons was hollowed into a mere shell. Dr. Wilks says, "Apoplexy (Cerebral Hæmorrhage) is very rarely, if ever, a suddenly fatal disease * * * *. Even when blood is effused into the pons Varolii, or the neighbourhood of the fourth ventricle, two or three hours elapse before the death of the patient." He continues, "Amongst the reports of several thousand post-mortem examinations (at Guy's Hospital), I can only find one case in which death was sudden, this was a case of meningeal apoplexy." Yet, even in this case it is not quite clear that death occurred instantly. The patient fell down near London Bridge station, and was dead when brought to Guy's Hospital.

Now, although Cerebral Hæmorrhage sometimes kills rapidly it does not kill instantly, as rupture of the aorta, or heart disease, sometimes does. This is a very important distinction, and I have been misled by disregarding it. A few months ago I made, with Mr. Ilott, an autopsy on a woman of middle age, who died in an instant, while sitting in her chair talking to her brother. As I felt confident that this patient had disease of the brain on each side, I confess I imagined hers might be an exceptional case, and that death might have followed even so suddenly some new bleeding into the pons, or medulla. We found in the head only the remains of old sanguineous effusions, one on each side of the brain, but the pericardium was filled with blood from a rent in the aorta. Dr. Wilks says, "With very rare exceptions we ought to ascribe sudden death to disease of the heart." He however adds, that this opinion is not generally held, and that we read every day in the newspapers of cases of sudden death attributed by medical men to apoplexy.

The question raises important medico-legal considerations. As a rule, very sudden death—apart of course from violent injury—does not lead to suspicion of foul play. If we are called to a patient who has died instantly, the probability is that he has died of heart disease or of rupture of a thoracic aneurism. If he die suddenly, let us suppose in five minutes, especially if there is known to have been convulsion, it is possible that there is Cerebral Hæmorrhage. This is especially likely to be the case if the patient be young, e.g. under thirty and in good general health, above all if there has been for
ON APOPLEXY AND CEREBRAL HÆMORRHAGE.

some time, days, weeks, or months, paralysis of a cranial nerve, especially of the third, or severe and varying head-ache. When, as in Dr. Anthony Roberts' patient's case, the sudden death occurred during a meal, we are likely to be goaded by hints that such a circumstance points to poison, and a legal inquiry will be demanded. Now the only poisons which could kill in a few minutes after they were taken are hydrocyanic acid and nicotine, most unlikely things to be given at a meal. Indeed, we should feel quite sure that death was not so caused, unless we could smell the poison. Suppose, however, that the patient died instantly after taking a dose of medicine, his friends would naturally suspect that death was caused by the dose, and we could not confidently say it was not, however grossly improbable it might be. If, however, the patient died suddenly some time after taking it, especially if at the beginning there were a single severe convulsion, we should think he died from disease.

So far as I can judge by Taylor's description of the symptoms produced by prussic acid, there is nothing by which I could distinguish them from those—except perhaps tongue biting—I saw, in the case of one patient a quarter of an hour before he died from rupture of a cerebral aneurism; and thus I can conceive we might sometimes make a mistake in this matter, if there was no smell of the poison to decide for us. The case I allude to was not doubtful, as the symptoms were known to have set in several hours before.

Suppose the patient dies in a quarter or half an hour, there may be more difficulty. A milkman was taken ill in his cart near the London Hospital, and quickly became insensible, and when in about ten minutes he arrived at the hospital he was dead. Now my colleague, Dr. Sutton, found nothing whatever wrong within this patient's body. The circumstances of the case negatived poison; but such a death, with no post-mortem appearances, after a meal would be the source of great difficulty, and I do not know, except by analysis or smell of poison, how we could determine, that it was not due to poison. If the symptoms set in about half an hour after a meal, or a dose of medicine, and coma comes on gradually, the patient might be suffering from Cerebral Hæmorrhage, uremia, or opium poisoning. If there were a convulsion or any paralysis, then there would be little difficulty.

It is important to bear in mind that coma from Cerebral Hæmorrhage rarely begins very suddenly, unless it sets in by a convulsion, or unless the bleeding be into the pons Varolii. This at least is the opinion recently brought forward by the late Professor Trousseau. When coma or insensibility from Cerebral Hæmorrhage occurs without a convulsion, it will come on after a little thickness of speech, or a little staggering, and the patient may be profoundly comatose in a few minutes; but Trousseau held that the patient, with the two exceptions stated, does not fall down instantly as if struck. Insensibility does not always set in suddenly when the blood is effused into the pons Varolii.

Now there are two chief ways in which the symptoms of Cerebral
Hæmorrhage are known to set in. 1st, by a convulsion, and 2d, without one. Coma after a convulsion has been already considered in detail; it will be further spoken of especially in connexion with hemiplegia.

Cerebral Hæmorrhage, when it does not occur with convulsion, sets in in very many ways. Let me just mention some of the ways in which I have known hemiplegia with coma begin. A man, forty years of age, finds his left leg drag as he enters a stable door, and directly falls hemiplegic and senseless. A man is observed to look stupid at his work, and a fellow-workman throws something at him to rouse him; the patient is found to be speechless and hemiplegic. A woman when being photographed calls out that she is losing the use of her right side, and becomes senseless and hemiplegic. A man goes out, begins at once to stagger, leans against a wall, and is believed by his friends to be drunk; he is quickly found to be insensible and hemiplegic.

But the ways in which coma from Cerebral Hæmorrhage may set in are really innumerable. The important practical consideration is as to the time that may elapse from the slight to the severe symptoms.

When a patient has suddenly, decided, although very slight, local palsy (for instance, a little thickness of speech, or one-sided weakness or numbness, or a trifling drawing of the face), it is clear enough that he has something wrong with his nervous system; and if from his age and state of system we consider it likely that the internal wrong is not of the sort which occurs with epileptiform seizures, or with softening, but with an escape of blood in nervous tissue, we have to bear in mind that the symptoms may not merely constitute a warning of some larger and more distant disaster, but that those very symptoms themselves may shortly, as it were, enlarge into fatal ones. I use the indefinite word shortly, because the interval may be a few minutes, a few hours, or a few days, or as already stated, the symptoms may pass off, and the patient may months after die of disease of some other organ.

If there were with the slight motor symptoms, severe pain in the head or vomiting, if the manner, apart from defect of speech, were much confused, we should fear a severe attack of Cerebral Hæmorrhage was just at hand. We should be sure bleeding was going on if one symptom, such as thickness of speech, was slowly followed by such another as weakness of one side, the more so if there were vague, startings of that side, and not steady cramp or spasm of one hand, foot, or side of the face.

Sometimes the first symptoms are vomiting and head-ache, without any local palsy. These two symptoms setting in suddenly, especially if they do not occur on getting up in the morning, but come on without any obvious provocation, should always lead to a careful consideration of the possibility of a Cerebral Hæmorrhage having happened. Suppose we find albumen in the urine and other evidence of chronic degeneration, this condition of the system, I think, would not negative the existence of a clot. The two symptoms may, it is true, be due to renal disease without clot, and they are likely to be owing to
renal disease, if the patient has the vomiting early in the morning after getting up, especially if he have already had it for many mornings in succession. Vomiting of bile, along with head-ache, is common among the indefinite series of symptoms which attend organic diseases of the brain, such as tumours.

I think that suddenly-occurring severe vomiting, or attempts at vomiting, continued far beyond the emptying of the stomach of food, with pain in the head, and temporary confusion of mind, are, in a patient with degenerated arteries and albuminuria, quite as likely to be due to small clots as to the circulation of anything which a man with healthy kidneys would not have in his circulation. These small clots may increase in size, and cause more dangerous symptoms.

Supposing we have doubts as to the real nature of what was wrong with any one who suffers any of the symptoms mentioned, the treatment is quite obvious. The great thing to do for a patient who may have a small effusion of blood in his brain, is to keep him quiet, in the hope that the clot will not get bigger; and when, from the appearance of decided confusion and weakness of one side, we feel that it is almost certain that a large clot is already lying in the floor of one lateral ventricle, we must adopt the same plan, in the hope that it will not increase in size, and break into the ventricle.

The consideration of the mode of onset of symptoms of Cerebral Haemorrhage is of great importance from a medico-legal point of view, even when the patient is lying profoundly comatose or dead when we reach him. The case of a patient who is comatose, or deeply insensible, should be considered at least from the following points of view:

1. He may be very drunk.

2. He may have a large clot in the pons Varolii, in his cerebral ventricles, or on the surface of the brain.

3. He may be poisoned by opium.

4. He may have been struck on the head, or he may have fallen down stairs in a fit.

5. He may be suffering from uræmia (Serous Apoplexy).

6. The coma may be epileptic.

7. It may be the result of rupture of a cerebral aneurism.

8. He may be the subject of that condition which is only known from its clinical symptoms, under the names of "Nervous Apoplexy," or "Simple Apoplexy."

9. Or there may be an abscess in the brain, meningitis, softening, a cerebral tumour, &c.

In most cases the patient becomes ill at home among his friends, or at his work, or he is found ill in bed, and in the vast majority of instances we are able to avoid mistakes; at least we steer clear of medico-legal difficulties—a most important matter. The patient need not suffer from our uncertainty, as we should always take great care of a man who is insensible from any cause, and if we were in doubt as to whether he were drunk or poisoned, we should treat him for drink or for poison. However, the patient may be found by the police
comatose on a doorstep, or he may become insensible in a public-house, or he may be found at the bottom of a scaffold, or in bed at an inn; or we may be called to an old woman who lives alone, and who may have fallen out of bed, accidentally, or in a fit. Yet even in these cases we mostly get right. The patient may have a severe convulsion, and this will negative drunkenness, as the sole cause of his insensibility. It makes poisoning, to say the least, very improbable. Suppose, however, there be no convulsion in a patient unknown, universally powerless and deeply comatose, we cannot tell from what he is suffering. He may have had a convulsion before we saw him. If we hear that he has had no convulsion, from the first, the diagnosis is most difficult. The insensibility may be owing to any one of the causes in the list. And if there has been a convulsion, repeated or not, he may still have large Cerebral Hæmorrhage. Or he may have received a blow on the head, he may have had an epileptic fit, be suffering from uræmia, or rupture of a cerebral aneurism, besides other rarer conditions. Now in deep coma, hemiplegia, a one-sided twitching, or convulsion affecting one side much more than the other, points towards hæmorrhage, and the case is, especially in a patient past forty, marvellously simplified. Still hemiplegia in coma is by no means always due to cerebral hæmorrhage. Besides, it is best to consider cases where there is hemiplegia separately, as we know that when the bleeding into a single cerebral hemisphere is large, or when hæmorrhage occurs in the pons, one-sided palsy is frequently not to be made out.

Then it is most important to bear in mind that we have combinations of the above different states. A drunken man may be struck on the head, or if he be habitually drunken, a fit of drunkenness may not improbably coincide with, and perhaps hasten on, the time when his cerebral arteries are ready to give way. Then an epileptic may fracture his skull and rupture the middle meningeal artery in a fit, and a person with diseased kidneys who is fast getting well of hemiplegia, undoubtedly from clot, may pass slowly or quickly into uræmic coma.

Now, in order to write briefly, I will consider the supposed case of a man or woman comatose under different circumstances and with varying symptoms. I have already spoken of age, degree of insensibility, stertor, conditions of pupil, and states of circulation and respiration. None of them nor the whole of them furnish any certain basis for the diagnosis of Cerebral Hæmorrhage.

Smell of drink is of no value beyond suggesting an examination for drunkenness. Now, many painful mistakes in diagnosis—all my readers will know of some—are made, especially by lay people, in this matter, and it is far too common for a patient who is supposed only to be drunk, to be left "to sleep it out," when, perhaps, besides being really drunk, he is suffering from Cerebral Hæmorrhage, uræmia, &c. We must not let such a suggestive circumstance as that the patient really had drunk much, or the fact that the insensibility came on in a public house, make the diagnosis for us.
A good many patients are brought by the police to the London Hospital from the Docks for dead-drunkenness, consequent on sucking wine or spirits out of a cask through a straw, and then, of course, the diagnosis is ready made. But from the general condition of the patient himself—were he beyond middle life—we should often come to the conclusion that he was suffering from a clot in his brain. I saw, with Dr. Woodman, a well-made, stout man, aged forty, who was known to have drunk a large quantity of spirits of wine. Dr. Woodman has recorded this case in the Medical Mirror, July, 1865. There was nothing, on ordinary examination, to enable us to say that the coma differed from that which large Cerebral Haemorrhage sometimes induces. But Dr. Woodman, who had charge of the case, found the specific gravity of the urine to be below that of water. The patient died. It is, of course, not common to find so striking an evidence of alcohol as an examination of this patient’s urine supplied. We might distil the urine (as was done in this case), and then we could detect a very small quantity of alcohol by the bichromate of potash test. But a still is not likely to be at hand, except in public practice. Then the mere presence of alcohol in the urine is not to be relied on to show that the patient is suffering from a poisonous dose of alcohol only. However, Dr. Anstie says that it would be possible to recognise the presence of a poisonous dose of alcohol in the system if one drop of the urine itself added to 15 minims of the chromic acid solution turned the latter immediately to a bright emerald green.* On an emergency this would be impracticable. I may here mention that Dr. Woodman had under his charge, as resident Medical Officer at the London Hospital in the year 1864, twenty-four cases of alcoholic coma, and in each instance the patient was brought into the hospital quite insensible, yet, in his remarks (Medical Mirror) on these cases, this very good observer relies with no confidence on any test to distinguish the coma of drunkenness from the coma which large Cerebral Haemorrhage causes. Dr. Woodman says, “I find, from published cases, and from my own MS. notes, that in alcoholic coma we may have the face either flushed or pale. The pupils may be either contracted or dilated. (I believe they are generally contracted at first and dilated after); sensation and motion may be either impaired only, or altogether absent, as in the case recorded. So, too, with reflex movements. There may be stertor or none at all; I believe it is generally slight in all alcoholic cases, except in the last scene of all. The body may be warm or cold, the limbs rigid or flaccid, and so on with other symptoms which it would be tedious to enumerate. The practical question then occurs with great force, ‘Are we able, in a given case, positively to diagnose

* The chromic acid solution is made by dissolving one part of bichromate of potash in three hundred parts (by weight) of strong sulphuric acid. Of course Dr. Anstie does not represent this test as a certain one for alcohol, but there is not likely, he tells me—and his experience on this point is very great indeed—to be any practical objection to the conclusion, when the reaction is so sudden and decided on the addition of but a drop of the urine to the test solution.
alcoholism from apoplexy, or narcotism from opium, &c. ?’ I fear that from the present state of our knowledge this question cannot be answered positively (in the affirmative).” Some authorities state that the breathing is stertorous in poisoning by alcohol, and others say that absence of stertor enables us to distinguish alcoholic coma from hæmorrhagic coma. When one-sided symptoms come on, as twitching of the face, head, or eyes, or if convulsions occur, we are easily able to form a diagnosis; but we cannot make it from any other circumstances than these and the sudden and decided chemical reaction alluded to.

If the patient can be roused to give his name and address, the probability is that he is slightly drunk, yet he may be in the early stage of opium-poisoning; but if he merely swears or says “what’s that to you?” the test is of little value. Even when we know that the patient has been swearing, noisy, and violent shortly before he became “insensible,” we must not hastily ascribe his insensibility to drink, even if he be known to have been drinking. Internal Cerebral Hæmorrhage—unless there be convulsion—rarely begins very suddenly; and patients who die of this are very often supposed by their friends to have been drunk when the attack was begun. Indeed, I should think it even probable that there was intracranial bleeding if such symptoms as stupor, thickness of speech set in, or increased rapidly in a noisy drunken man, especially if he have had a fall, even a slight one. I have known a drunken man die with hæmorrhage over one hemisphere, in whose urine Mr. George Mackenzie found alcohol. The patient had had a slight unheeded fall, and was one of those left “to sleep it out.” Did space permit I could relate many cases, in which even able men have made mistakes in diagnosis. A drunken man is very liable to be struck on the head, or to fall on the kerbstone, and a very slight injury will give rise to effusion of blood in the arachnoid cavity, and it is well known that a man may have effusion of blood on the surface of the brain for some time before any symptoms are caused by it. In many of these cases, the stupor from gradual squeezing of the brain will mingle with that from drink.

Suppose we find bruises on the head, whether the patient has been drunk or not, we have then to consider whether he is suffering from a blow on the head. Even if there be no bruise we have still, when the patient has been found in the streets, or at the bottom of a ladder, to raise the question of injury. Even if the patient have been in the way of injury several days before any insensibility came on, we must still consider the possibility of effusion of blood being the cause of his symptoms.

Now an external bruise to the head, especially if there be swelling from extravasated blood, renders it very probable that the patient’s coma is due, partially or entirely, to injury; he may have been injured by a slight fall on the kerbstone, he may have been struck on the head, or he may have injured his head in a fit. The position of the bruise is obviously a very important matter in diagnosis, and it may be the
only valuable evidence in diagnosis, as in the case of a known epileptic who is found comatose after leaving a public-house drunk. In the instance I am thinking of blood was effused in the arachnoid cavity. A bitten tongue would make us incline to the diagnosis of injury to the brain in a fit, and if the coma was very deep, and if without any convulsion it gradually deepened, we should usually so decide: if the coma were decreasing we should think the patient had suffered in his fit no more than an external bruise. Still if the bruises were in such a place as on the vertex, whilst we might suppose the patient was suffering from injury, we should think the injury was not received in the fit, but that he had been struck, and then the insensibility would be more likely to be owing to the blow, than to the fit solely.

But it must be confessed that when there is no local palsy to be made out, we can never be quite certain that bruises indicate that the insensibility is due to effusion of blood inside the head. We look in all cases for ecchymoses under the conjunctiva and for bleeding from the nose and ears; and if we find them, especially if we can determine paralysis of the portio dura nerve, our difficulties in diagnosis from non-traumatic haemorrhage are usually at an end. These are far more useful signs than severe bruises to the head. Then, on the contrary, we must most carefully bear in mind that the absence of external bruises, whilst it renders it improbable, does not negative intracranial mischief from injury.

We are obliged to rely very much on the circumstances under which the coma came on, if we can fortunately get to know them. I do not speak of clear cases, such as when a man falls into a ship’s hold. The presumption is, that if coma occurs after a fight, or a fall when drunk, or down a staircase when sober, it is due to injury. However, if the patient die instantly, within a few minutes after an injury or a fall, the probability is that he has died either of heart-disease, or that he has broken his neck.—(Prescott Hewett.) It is just possible that a blow might lead to rupture of an aneurism of a large cerebral vessel, and then death might occur in a few minutes. An injury to the head, leading to extravasation is rarely so rapidly fatal, and sometimes there are no symptoms for days, and occasionally no symptoms at all when the blood is found into the arachnoid cavity.

If there be hemiplegia directly after a fall, it is almost certain that the patient fell, because he suffered non-traumatic haemorrhage; but if, after an interval, either hemiplegia, convulsions, or insensibility comes on, it is more likely that there is traumatic haemorrhage. The exception to the first is, that now and then, the brain is much lacerated by a blow; and to the second, that meningeal haemorrhage comes on from disease, and also produces symptoms after an interval. Now, if we found that the patient had albuminuria, diseased arteries, and if he were above forty years of age, we should think the haemorrhage was non-traumatic; and if the patient were young and healthy, that it was traumatic.

When the symptoms come on after an interval of a day or more—
say a drunken man falls in going up stairs to bed,—we may have very
great difficulty, even at the autopsy, in saying to what effusion of blood
is owing. If the blood be effused into the brain substance, away
from the surface, without bruising or tearing of brain, the haemorrhage
is, I think, probably non-traumatic. It is certainly so if there be
evidence of wide degenerative changes. If in the pia-mater it is
probably traumatic if the patient be young and healthy; probably
non-traumatic, if he be past middle life, and have degenerative changes.

If we do not let the mere circumstance that the patient has been
struck, or the presence of granular kidney, which is always in favour
of non-traumatic haemorrhage, decide for us, we frequently cannot
decide. If the blood be in the cavity of the arachnoid, it is probably
from a blow; it is certainly so if it lies over the dura mater.

Suppose there are no bruises, and no signs, and no history of injury.

If the pupils be minutely contracted, the patient being profoundly
comatose, and universally powerless, we consider two chief possibilities,
viz. effusion of blood into the pons Varolii and poisoning by opium.
Now the pupils are not always contracted when there is haemorrhage
into the pons, and they are sometimes dilated in cases of opium-
poisoning. Moreover, a minutely contracted state of the pupil in either
condition is replaced by a large or very wide one shortly before death.
Again, whilst it is true, that symptoms of opium-poisoning nearly
always set in slowly, and effusions into the pons rapidly, yet, now
and then, the symptoms of opium-poisoning will begin quickly, and
the symptoms from effusion into the pons may set in at least de-
liberately. For instance, I have seen two cases of patients who had
come off a scaffold, because they felt giddy. Nay there need be no
loss of consciousness at all when the pons is damaged; but then we
should in all probability find cross paralysis.

Still effusion into the pons never, so far as I know, imitates the
gradual sleepy condition of opium-poisoning, and if it begins slowly,
it in a few minutes makes a sudden leap, often with a convulsion.
If we could rouse the patient we might incline to opium-poisoning;
but I attach little value to the test. The symptom of greatest diag-
nostic value is convulsion, whether it begin the case or occur later.
This symptom is frequent in Cerebral Haemorrhage; it is very rare in
opium-poisoning in adults. "Still convulsions are sometimes observed
before death, especially in children." (Taylor.) And my friend, Dr. W.
Procter of York has given me notes of a case of rapid death in con-
volusions of a woman, aged thirty-four, who had taken six grains of
morphia. If the patient present any one-sided symptom, such as
 twitching of the limbs, drawing of the face, or if one pupil only
were minutely contracted, we should suppose the patient was suffer-
ing from Cerebral Haemorrhage.

If the patient be dead when we are consulted we should think he
had died of Cerebral Haemorrhage if death occurred in less than six
hours. Poisoning by opium proves fatal in from six to twelve hours.—
Taylor. Effusion of blood into the pons will kill at varying times,
from a quarter of an hour, which is rare, to twelve or more hours. Dr. William Procter has recorded a case in which an ounce of laudanum killed a woman, fifty years of age, in less than two hours.

In all cases we examine the urine for albumen. I have already considered uræmia in the article on Convulsions. To that article and to other articles in this volume I must refer. I may, however, say here, that I attach less and less importance to the diagnostic value of the mere presence of albumen in the urine in cases of coma, i.e. cases of emergency. If, for instance, the patient be comatose, universally powerless, and have contracted pupils, he may be, if there is a convulsion, suffering either from uræmia, or effusion of blood into the pons Varolii; and if there be no convulsion there is a third difficulty, viz. poisoning by opium, perhaps by a medicinal dose if the patient have granular kidneys. I have recently seen one case, a woman found in the streets, in which diagnosis was impossible, betwixt opium-poisoning, effusion of blood into the pons, and uræmia. I do not think the presence of albumen in the urine renders it even probable that a comatose patient is suffering from uræmia if he have no convulsions.

Serous Apoplexy.—Here it seems to be the place to say something of serous apoplexy, or rather of the term. Dr. Wilks says: "The so-called serous apoplexy is a disease of which I know nothing. It was a term formerly used to designate those cases of very speedy death with coma, where no blood was discovered in the brain. There can be little doubt that the majority of such cases were instances of Bright's disease, and that death was due to what is now called uræmic intoxication. If you read the cases given by Abercrombie of the state of health of his patients, and all the accompanying symptoms, it can leave no doubt on your mind that many of them were instances of Bright's disease. Apart from such, however, we do occasionally meet with cases of very rapid death from evident cerebral affection, and yet scarcely anything to account for it is found on examination. But as in these there is no necessary increased effusion, the term 'serous apoplexy' cannot be used. It is a term I never adopt, nor do I know to what class of cases it is applicable."

I follow Dr. Wilks and others in believing that the so-called "serous apoplexy" is usually uræmia although every one admits that there are cases of rapid death in coma, with or without convulsion, in which we can find neither renal disease nor any other cause for the comatose condition. These cases are what have been called 'simple apoplexy.' It is not denied that in some cases there is a very unusual amount of serum in the brain. That there is much serum in the meshes of the pia-mater is not, I submit, a fact of great moment, so far as accounting for sudden coma goes; and we must never forget, when we find much serum in the pia-mater under the visceral arachnoid, that the fluid may be merely filling the space which wasted convolutions cannot occupy. This compensation is most striking in cases of extreme wasting of the convolutions of one hemisphere, such as I found in the girl whose case is mentioned elsewhere.
Now, supposing we have excluded drunkenness, injury, and uræmia, we have still to determine whether the case be not one which, for want of better knowledge, we can only name from its negative post-mortem appearances, Simple Apoplectic. A patient—sometimes even a young man—quickly becomes insensible, and dies in a few hours, and in the whole body we find nothing abnormal which can reasonably be supposed to have been the cause of the symptoms. This class of cases is well recognised, and instances will have occurred in the practice of most of my readers. Dr. Wilks says, in his Lectures on Pathology: "Occasionally you may be called to a case where the patient is insensible or suffering from apoplexy, and on examining the brain, you find nothing. During the last two years I have seen two cases where the post-mortem revealed nothing." I have already spoken of patients dying after attacks of convulsion, stating that—of course excluding those who have diseased kidneys—in some we find marked changes post mortem, and in others we discover nothing in any part of the body. But patients pass into coma when no convulsions have been observed, or after apparent recovery from a convulsive seizure. It seems certain that these patients die from the brain; at all events, they die in the same way as patients do who die in coma from Cerebral Hæmorrhage, and in such cases during life Cerebral Hæmorrhage is frequently diagnosed. The post-mortem appearances of the heart and lungs are the same as those we find in patients who have died with clots in their brains.

I freely confess that I know no certain rules by which to distinguish simple from sanguineous apoplexy. We cannot rely on the kind of pulse, nor on the temperature, nor on the state of the pupils, nor on stertor. I have observed that some medical men seem, if I may use such an expression, to be disappointed in not finding in the head of a patient who has died in a dramatic manner anything which can have given rise to his symptoms. In these cases the suspicion of poisoning will occur. Indeed, this possibility ought to be carefully considered. Yet this part of the question is legal rather than medical; and at an inquest we can assure the coroner—who, if he be a medical coroner, requires no strong assurance on the matter—that the profession recognises these cases as cases of natural death.

Many eminent men believe that a more or less sudden increase of blood in the head may lead to death. In a case about which one would say that there was no cause for death discovered, another would point to the fulness of the cerebral veins as a sign that there was not only more blood in the brain than there ought to be, but enough to kill, supposing the congestion occurred suddenly. Again, when there is more serum than usual in the head, the patient will sometimes be said to have died of serous apoplexy. Of this I have just spoken. I do not myself think that the increase of blood one finds in the cerebral veins of a patient who had died "apoplectic," without structural lesion, can be supposed to have been the cause of his seizure.
ON APOPLEXY AND CEREBRAL HÆMORRHAGE.

It is more likely to be the effect of the disorder of respiration which attends deep coma, however produced. The lungs of these patients are often black, sodden, and soft, and thus no wonder that the cerebral veins are full too; so that, while the existence of cerebral congestion is not denied, it may be doubted whether it causes severe cerebral symptoms. Indeed, in certain cases of even large Cerebral Hæmorrhage, it is not easy to say why the patient has coma. I say certain cases, for it is convenient to exclude from the illustration cases of hæmorrhage into the pons and cases in which blood has escaped into the ventricles. The loss of a certain quantity of the corpus striatum and hemisphere, let us say of the right side, may be borne without any loss of consciousness; but the patient generally becomes unconscious for a shorter or longer period when this part of the brain is more or less torn up by even a small clot. The loss of consciousness is not due, therefore, to a want of an important part destroyed, for the patient may be quite conscious a few hours later, and after living for years, large damage may be found to his brain. This temporary stupor may be put down to congestion. But soon after the effusion of a large clot in the brain has rendered a man unconscious, the pulse may be normal, the respiration quiet and natural, the surface cool, and the vessels of the optic discs apparently healthy. Later, respiration is impeded, and then the face is turgid and the cerebral veins are filled; and I have found in one case of meningeal hæmorrhage the retinal veins black and unusually distended. Trousseau, who has considered all these points in a most masterly manner, thinks the phenomena, which are often ascribed to congestion, are usually due to what he calls Cerebral Surprise. There is a stupor which, as he points out, may occur without congestion; as when a bullet is introduced through a trephine hole in the skull of a dog or rabbit, and is placed betwixt the bone and the dura mater. I would myself say that I do not know how it is that patients who die of simple apoplexy, or whose deaths are put under this name, become ill, nor what the change is in the brain or body. I say change, for although there is no lesion discovered, there must be something wrong, and the most careful search should in all cases be made in the different viscera. In some cases we may find degeneration of the cerebral vessels, but that is not enough to cause death; but in others we do not find even this. There being, doubtless, something wrong, something is overlooked at post-mortem examinations; but in the few cases I have seen, nothing has been overlooked that the most careful examination I could make could discover.

It is impossible, from want of space, to consider more difficulties here. The articles on Cerebral Softening, Meningitis, and Abscess of the Brain must be referred to. It is true that he who does not consider these possibilities among the more common ones will not often be wrong, as these changes rarely cause sudden coma. But I could relate cases showing mistakes in cases of convulsions, hemiplegia, and insensibility, from neglect in considering these rarer causes.

**Hemiplegia with Coma, following Convulsion.**—Unfortunately, the
history we receive of "fits" is often very vague, and, in popular speech, a fit does not always imply a convulsion. To find out that a patient has hemiplegia from damage to the brain is usually an easy matter, and in most cases from sudden deep coma occurring in a man past forty years of age, our predictions are generally right as to the nature of the damage. Still, the case of a patient who is hemiplegic and insensible after a convulsion, should be considered at least from the following points:—1. Epileptic hemiplegia, with or without organic disease of the brain. 2. Local softening of the brain, with or without plugging of the middle cerebral artery, or some branch of it. 3. Effusion of blood on the surface of the brain, or into its substance.

Yet, if we find a young man hemiplegic and comatose, especially if after a severe convulsion, the great probability is that he has had an epileptiform seizure, followed by epileptic hemiplegia; that he will get well, and that he will have fits again after an interval of more or less of apparent health. But this is only probable because it is most frequently so. I know of nothing in the nature of the paralysis or in the sort of coma to distinguish the case from one of Cerebral Hæmorrhage. There are these very useful and yet somewhat unsatisfactory generalities; that the coma is usually less profound, and the paralysis usually less in degree. I have mentioned the case of a girl, whose hemiplegia after a fit, really due to a clot, I should have considered epileptic had I not searched beyond the mere symptoms,—convulsion with some tongue-biting, followed by hemiplegia. The age of the patient is of some diagnostic value. Hemiplegia and insensibility, after a convulsion, are generally due to clot after forty, and to other diseases, e.g. cerebral tumour, syphilitic disease of the brain, &c. under the age of thirty. Yet the girl whose case is just referred to had a large clot in her brain. We must then examine the system very carefully. If we found the urine albuminious, if we also found rigid arteries, hypertrophy of the left ventricle of the heart, and above all, if there were retinal degeneration, we might conclude that the insensibility and palsy were due to clot in the brain at whatever age the patient might be, and that the coma was the result of the disturbance it induced. I do not say that a convulsion in patients so unsound usually indicates clot—it certainly does not—but that a convulsion followed by one-sided palsy, does. But if there be no albumen in the urine, nor other signs of degeneration, and if we have no history, we can only say with certainty that the paralysis points to something wrong on the opposite side of the brain, but whether that something be clot, aneurism of the middle cerebral artery, tumour, or those undiscovered changes which attend simple convulsions, we have no evidence to determine, beyond the great and very valuable probabilities which age, &c. supply.

Now suppose we know more of the patient. If he has been liable, even for months only, to severe fits of the same kind, and to palsy after them, or after the worst of them, we feel pretty confident that there is no clot, and that the patient will usually come round, even
if the fits repeat themselves, and if the coma deepen. The longer the patient has had the fits, and the younger he is, the more certain we are in our diagnosis. We may be, I think, quite certain if the fits are wont to begin deliberately by cramp of one hand, or one side of the face, or in the foot. In a recent case, (let us suppose the patient has had no fit, and no palsy before) the previous existence (say for a few weeks) of intense pain in the head—there being no albuminuria—especially with purposeless vomiting—above all, if there were optic neuritis—we should usually be right if we decided against clot. I am compelled to speak vaguely, as we know that a man who presents the symptoms of tumour of the brain, such as those just mentioned, is prone to convulsions of a simple character, and also liable to convulsions, coma, and death from bleeding into the brain from the tumour itself, if it be a vascular one. So then unusually profound coma and hemiplegia, or unilateral twitchings following a convolution in a patient, especially a young patient, who has had symptoms of cerebral tumour, and even convolution before, would oblige us to consider the possibility of a hæmorrhage which might quickly lead to death.

But the symptoms may have been due to cerebral softening. Now, as a rule, there is, when the cause is plugging of the middle cerebral artery, no convolution, and when there is a convolution it is usually slight. Again, when the softening is not obviously due to embolism, there is, as a rule, no loss of consciousness and no convolution. But this rule is by no means absolute, and, I confess, I know of no circumstances beyond the general considerations of degeneration, of age, the presence of heart disease, &c., to decide for us. The occurrence of rigidity soon after an attack of paralysis is not, I think, of very great diagnostic value. The sort of rigidity is of more value. The arm is fixed in a more natural position. In softening, the arm is flexed, and the hand is grasped more like a fist, the thumb being either in or out. But this condition of the muscles occurs also in some cases of the status epilepticus, very frequently in hemiplegia in young people, and with hæmorrhage on the surface of the brain.

When the hemiplegia is associated with tumour of the hemisphere, it more quickly passes off, or rather it very quickly diminishes, and then the arm, on being used, often moves in irregular jerks, and the patient is subject to occasional fitful spasms in the limb, as well as more definite "partial fits." When the coma is over, if there be complete loss of power, the great probability is that the case is one of hæmorrhage.

The previous existence of vague mental symptoms, such as irritable temper, defect of memory, would be some evidence towards softening, whilst the presence of the general signs of degeneration would point to clot.

**Hemiplegia with Insensibility not following a Convulsion.**—I have already spoken of the ways in which hemiplegia from Cerebral Hæmorrhage without convolution sets in, and have therefore said
much that obviously applies to the subject of the present note. I need not recapitulate the suggestions which age and signs of degeneration give. By what has gone before, epileptic hemiplegia and hemiplegia following injury have been considered.

The older the patient is, the deeper the coma; and the more decided the paralysis, the more likely is the apoplectic condition to be due to Cerebral Hæmorrhage. Hemiplegia with great loss of consciousness not following a convulsion, is far more likely to be due to Cerebral Hæmorrhage, than hemiplegia with insensibility after a convulsion. If there be no valvular disease, no evidence of syphilis, it is still more certain; and if there be renal disease and other signs of degeneration, it is almost absolutely certain. The point of diagnosis is chiefly from softening. As a rule there is no loss of consciousness in hemiplegia from softening. Yet there is sometimes. Again, loss of consciousness does not always occur with Cerebral Hæmorrhage producing permanent hemiplegia. Still, most frequently we are saved from mistakes by considering the age of the patient, the way the palsy came on, and the state of his system.

Sometimes, however, hemiplegia with loss of consciousness results from plugging of the middle cerebral artery. But, as a rule, when hemiplegia occurs with heart disease—and in these cases we may, in young people, during life, reasonably infer softening from plugging of a blood-vessel—there is usually no loss of consciousness of any continuance.

Dr. Dickinson has, in a most valuable paper in the first volume of the St. George’s Hospital Reports, related cases of the formation of coagula in the large blood-vessels supplying the brain, the symptoms in some of which could not, as he points out, have been distinguished from those of Cerebral Hæmorrhage. In some of these cases there was hemiplegia.

Hemiplegia without Convulsion and without Loss of Consciousness.—Although for convenience we separate cases of hemiplegia setting in with loss of consciousness, from those in which it come on without any mental confusion, there are all degrees from coma to clearness of mind.

We can now further exclude the gradually setting in of hemiplegia into which unilateral choreal movements sometimes slowly degenerate; the slowly creeping hemiplegia, say at its worst in a week, which now and then, and yet rarely, occurs with tumours of the cerebral hemisphere; and the local limit which the title of this article supplies, puts spinal hemiplegia out of my way. I need say nothing of hemiplegia in children. None of these cases are very

---

1 It is important to consider in the cases I am now speaking of, whether a seeming mental confusion be a general confusion of mind, or solely or chiefly that more psychical loss which occurs with or constitutes Defect of Expression, Loss of Will, and of which the most prominent sign is inability to talk or talk well (Asphasia).

The subject of Defects of Language has to be discussed with the physiology of mind and movement, and with the anatomy of the brain, and not in connexion with any particular sort of damage such as Cerebral Hæmorrhage.
likely to be mistaken for cases of Cerebral Hæmorrhage. I have also spoken of unilateral numbness, and I will now speak of those patients only in whom there is enough paralysis to enable us to be certain of its existence, independently of the assurance of the patient that he is weak or has numbness of one side.

Hemiplegia coming on suddenly beyond adolescence might be ascribed to (1) clot, in or on the brain, (2) local softening, (3) hysteria, (4) the paralysis might be pretended.

The chief points which put us right are the age of the patient, the condition of mind when the seizure occurred, premonitory symptoms and degenerative states.

It is most improbable that hemiplegia is due to clot if it occur in a patient under thirty. Indeed the diagnosis of clot must not there be made if there be no signs of degeneration; but it would be warranted if the arteries were rigid, if there were granular casts in the urine, and above all if there were degeneration of the retinae. But I cannot call to mind a case of hemiplegia, from clot, in a young person, in which there was no convulsion.

Again, it would be improbable that, at any age, the hemiplegia was due to clot if there were no loss of consciousness, or only a few seconds confusion when it came on. Nevertheless, it is quite certain, that hemiplegia from clot does come on sometimes without any known loss of consciousness. I have seen a clot in the optic thalamus of the body of a man who, some months before his death, described to me very circumstantially the manner in which the paralysis this clot had caused had set in. I could relate two cases wonderfully alike in the mode of outset—loss of consciousness in neither—in each of which the lesion was different—clot in one, a large patch of softening in the other. When we remember that some epileptics do not know when they have had fits, it is not perhaps reasonable to be absolutely certain that there was no loss of consciousness in most cases. If, however, we find, as I found in the case of hemiplegia, fine clots just cited, signs of degeneration, we may venture to diagnose clot, and we may almost certainly do so if, as in the first case alluded to, we see hæmorrhages in the retinae and hear of epistaxis.

Here, more than anywhere, I feel that since the necessity of scientific proof of statements requires post-mortem examinations, our knowledge of hemiplegia of the sort I am describing is likely, from very carefulness, to be one-sided. We obtain few post-mortem examinations of those patients who become hemiplegic without any loss of sensibility. Many patients who so suffer, whether they get rid of the palsy or not, have, or attain to, a fair state of health, and do not die for years after, and thus we do not see what lesion has really been the cause of their incapacity. It is true that we make a few autopsies on the bodies of those who have long been paralysed, but we rarely obtain a good history of the early part of the case. Therefore, I think there are often no means of being quite sure as to the cause of hemiplegia occurring, with or without insensibility in people beyond middle age.
The presence of heart-disease, pregnancy in young women, rheumatic or scarlet fever, would point to softening from embolism. Syphilis produces hemiplegia in two ways; a lump of syphilitic deposit in the hemisphere leads to a convulsion and hemiplegia. I have spoken of this. But an artery may be much diseased and narrowed by syphilitic disease, and the sudden blocking of the middle cerebral artery may lead to hemiplegia, with or without insensibility. There is nothing in the nature of the hemiplegia to warrant a diagnosis; but apart from obvious signs of syphilis, we may infer the cause by observation of or inquiries about affections of cranial nerves.—(See p. 516).

It is not necessary to say much here on hysterical palsy. It is really very difficult to diagnose it, I think often impossible, to say to what hemiplegia in young people, fairly healthy, is owing. Some consider the difficult cases in the woman to be hysterical; but it is commonly easy to say that the case is not one of Cerebral Hæmorrhage. Besides, hysterical women stiffen their paralysed arm and leg, and grasp the hand in too good an imitation of a fist. Then, but this point goes but little way, there is no facial palsy. Moreover, they will pretend to absolute loss of sensation in parts paralysed, which is improbable, except shortly after the attack. The voice will be lost, and loss of voice, as far as my experience goes, does not occur with hemiplegia; or they will pretend to be speechless, and yet will write glibly. Now hemiplegia with loss of speech, and yet with ability to write well, is an extremely unlikely thing.

It is generally easy to tell when a patient is shamming hemiplegia, but now and then there are cases of great difficulty, and we have even difficulty in deciding whether there be a clot or not. Here again the limbs are stiffened in a straight line, the patient pretends not to feel the severest pinching, there is no paralysis of the face or tongue, the patient particularly dislikes low diet, and above all dreads the galvanic battery. Sometimes we really cannot tell at first. I have known a patient, profiting by a scar which deviated his face, give us much trouble, but the galvanic battery "cured" him. The quiet pulse and respiration and calm face would not decide against clot (see p. 532). I was once asked,—I believe in jest—to see a patient who had genuine hemiplegia, from disease of the pons Varolii: his face was turned to the left, and his left limbs were paralysed. The poor fellow had had an attack of hemiplegia before—no doubt—and he had heard two doctors disputing as to which side the face ought to be drawn. Low diet "cured" this patient very rapidly.

Prognosis.—As I have tried to point out, it is no easy matter to tell whether a patient has Cerebral Hæmorrhage or not, especially when there is no hemiplegia. Therefore when a man of middle age recovers from coma, we are not justified in saying that he has recovered from Cerebral Hæmorrhage. It is most likely, if there has been convulsion, and the patient comes round in a few hours, and is "well" next day, that he has recovered from that unknown temporary condi-
tion of the brain which occurs with seizures called epileptic, and that he will continue to be subject to fits. When coma occurs without a convulsion, and the patient gets well, we frequently cannot say what his condition has been, unless from the state of his urine, we can infer uræmia. Indeed we have seen that some patients even die in coma, and we find nothing in their bodies to explain why they became comatose, and why they died in coma. It may be that these patients were ill, or died because their cerebral vessels became suddenly very much fuller of blood than they ought to be; but I confess, as I have stated, that I have no clear notion of the nature of the change, causing the symptoms in these cases.

Let us suppose, however, that we feel sure the patient has a clot in his brain. When blood has got out in small quantity and has produced an unimportant symptom, we have to look far beyond it, the prognosis depending entirely on what we can learn of the state of the patient's system. Of this I have spoken sufficiently.

When blood has presumably escaped in large quantity, the deeper the coma, the more the stertor, the more decided the hemiplegia, the more likely is the patient to die. (I add the symptom, hemiplegia, because without it the diagnosis of clot is very difficult, and when there is no clot, recovery may follow from very deep coma, and as in alcoholism, after a very slow rate of pulse and respiration.) If the symptoms began by a convulsion, the case is likely to end fatally in a few hours, but this is by no means certain. A convulsion followed by hemiplegia, when it indicates clot, points to a large one, but a patient may live many weeks after a large effusion on one side of the brain. A large clot in the neighbourhood of the corpus striatum does not always produce convulsion. If the convulsion be followed by deep coma, irregular pulse and universal powerlessness, the Prognosis is very grave. There is either an enormous clot in one hemisphere, or the ventricle opened, or there is blood in the pons in large quantity. The patient is almost certain to die, however the coma sets in, if the pulse and respiration become quickly very abnormal, either below 60 or above 120, especially if they be irregular. If convulsions occur minutes or hours after such mild symptoms as defect of speech or one-sided numbness, the prognosis is very unfavourable. If after the existence of distinct hemiplegia only, with or without loss of consciousness for minutes, hours, or perhaps days, the whole of the limbs become quickly relaxed, the patient will in all probability die soon, especially if the change sets in with a convulsion. Minute contraction of the pupil, with universal powerlessness, especially after convulsion, is a bad sign, and so also is the coming on of very wide dilatation after a normal or a contracted state of the pupil.

Let us now suppose that after twenty-four hours' insensibility our patient is still living. If the insensibility continue, if the pulse and respiration be very rapid—above 130 and 30—if the skin be hot, and temperature above 100, he is likely to die. Very bad signs are those furnished by râles all over the chest and in the throat, by retracted
belly, especially if the abdomen is drawn in during inspiration, the lower ribs jerking strongly out. It shows that the lungs are getting full of blood, and after death in a few hours' coma, they may be black, sodden, and break down easily under the finger.

As favourable signs may be mentioned, a preservation of, or a return to a rate of pulse and respiration neither very slow nor very rapid, a diminution of insensibility, and an absence of convulsions, and twitchings, and rigidity. These are truisms. If however the return to a partial consciousness be attended by great restlessness, and if the return is rather to unregulated action, a slight delirium, turning over in bed, trying to get up, to sit up, staring about, &c., the prognosis is still unfavourable. If the patient recovers so far as to give his name when roused, although he soon dozes off again, the fact is favourable; but if he merely grunts and pulls up the bed-clothes, or pushes our hands away with his non-paralysed arm, the result is of little value. Whatever be the improvement of consciousness, if the pulse continue to be very quick, especially if it be irregular, or occasionally irregular, the prognosis is still unfavourable.

The patient may come to himself in a few minutes, hours, or days. The sooner he becomes sensible, the greater is the probability that the clot is a small one. But when actual insensibility has disappeared, the mental condition of the patient may be very deplorable.

He may be speechless, or he may simply articulate badly. There are all degrees of defect of speech and mind after Cerebral Haemorrhage. I do not say however that Cerebral Haemorrhage in particular produces the condition I am about to describe, although I think the worst cases of loss of speech and of imbecility with hemiplegia are produced by clot. Still the very worst case I have seen, and one very like the illustration I am about to give, was produced by softening.

A hemiplegic patient, aged forty-nine, may, on coming out of coma, which had followed convulsion, be only able to say "yes," and may lie in bed heedless of everything except the approach of food. He may pass all his motions in bed, and may daub himself with faces, and indeed be little more than a digesting apparatus, never making a sign for anything whatever, nor, for instance, taking any notice of his wife who comes to see him. From this painful condition there are all degrees down to a difficulty in articulation with an almost intact mind.

Leaving the illustrative case for a while, let me say that a large defect of speech, I am convinced, points to a large damage near the motor tract, and it is therefore an unfavourable symptom. There is rarely any defect of speech beyond a day or two when the paralysis is of the left side.

A patient who has extensive local disease of his brain of any sort, is liable to what Trousseau has called cerebral fever. They have severe pains in the head, and perhaps optic hallucination and vomiting. Now a patient who has a large clot in the brain, besides the more immediate symptoms already spoken of, and excluding uraemia in those who have
ON APOPLEXY AND CEREBRAL HÆMORRHAGE. 539
diseased kidneys, is liable to a sort of chronic, or to an acute cerebral fever, since besides being damaged in an important place, he has a "foreign body" in his brain. Such patients are at first voracious (here I continue the illustrative case), although they continue getting gradually thinner. Their voracity is either that they want food often, or that they really take it in large quantities. Then they may become worse rapidly, getting thinner, the belly sinking in, the pulse becoming irregular, the appetite ceasing, sleepy stupor creeps on, towards the last the skin becomes very hot, beads of perspiration stand on the face, the cheek falls in, the mouth stands open and the tongue dries; the pulse 150 or higher, respiration is very quick, and the inspiration short, and the patient dies. Great destruction of the corpus striatum is found post mortem.

This way of dying is not peculiar to Cerebral Hæmorrhage. Young people, who have at the autopsy perfectly healthy organs, and who are even robust when the illness has fairly begun, except for cerebral tumour, will die in the same way. However, a clot in the brain more rarely leads to death in this way than other "foreign bodies" in the brain, and if a patient has come round from coma with hemiplegia, with or without defect of speech remaining the worst that happens to him, so far as the blood already effused is to blame, is permanent hemiplegia, and speechlessness.

The patient may present signs of impaired mind, other than loss of speech (the cases I am thinking of are those of hemiplegia of the left side without loss of speech). However, the above severe and the following slight signs are not characteristic of Cerebral Hæmorrhage. On the contrary, mental symptoms, other than loss of speech, are rare in brain lesions of this kind, and when they occur they are not due to the local damage of the clot, except probably when much of the hemisphere is destroyed near to the left corpus striatum. It can therefore receive but passing allusion. There may be much irritability of temper, with great shrewdness in fixing fault on others; great selfishness about small personal comforts, with carelessness as to the larger interests of family. Thus I have known an affectionate father become so changed after an attack of paralysis, that, whilst he cared much about his dinner, he seemed to care nothing about news of his son, who had been to his former distress missing for years. These signs of a failing mind are accompanied by an inability for the simplest continuous mental exertion; for instance, the putting letters in order, giving a bare list of property, &c. This condition may merge into a state of great imbecility, in which the patient keeps his bed for several years, talking only to complain of being disturbed, lying with knees drawn up, head crouched down, his time being marked only by the periodicity of his appetite.

Now I come to consider the prognosis in cases in which the patient has been from the first hemiplegic only, with or without defect of speech, or in which the patient has come very quickly out of coma hemiplegic, with or without defect of speech.
When there is a very little palsy after a seizure, perhaps gone in a few days or a week, the patient may be, as has been repeatedly indicated, in worse plight if he have signs of degeneration, than if he be permanently paralysed without such signs. The fact that a patient who has been comatose and hemiplegic from clot, recovers from palsy quickly, does not, however, always point to a small clot, but it does so generally. The clot may be lying outside the lateral ventricle. Again, absolute recovery from paralysis does not indicate that a quantity of the motor tract has not been permanently destroyed. We find cavities of considerable size in the corpus striatum or optic thalamus of patients who have got rid of their paralysis.

Let us suppose, however, that we conclude that our hemiplegic patient has a clot in his brain, there being hemiplegia of the common sort, and that the clot is in the motor tract. Now if there were no loss of consciousness we really could not be quite certain it was due to a clot. But we may at least say that if a patient have hemiplegia without loss of consciousness, he will in the majority of cases, get rid of his paralysis, and at all events that he will not die soon, although he may remain paralysed. Great age of the patient does not contra-indicate recovery, if there be no loss of consciousness, nor does completeness of the paralysis at the first. If, however, the palsy does not diminish a little at the end of a week, it is likely to be permanent. A large implication of the face and tongue is usually unfavourable, except, I imagine, when the cause is embolism. The fact that the paralysis of the leg passes off altogether is no great encouragement to the hope that the paralysis of the arm or the defect of speech will disappear also, unless it has already been rapidly diminishing. An increased ability to swing the arm from the shoulder goes for very little. Whilst the fingers and arm remain supple—not getting red, swollen and sausage-like—there is likelihood of recovery. But the signs that make us fear recovery is hopeless, are continued rigidity and pain in the arm on movement. These seem to me to show that the higher motor tract has ceased to govern the arm, and that the fibres betwixt it and the arm are wasting. The hand will usually become lax when the patient is warm, and the fingers will sometimes open when the patient yawns. These signs do not encourage us much.

But, as far as I know, there is nothing characteristic of Cerebral Hæmorrhage in the above. However, the limbs partly paralysed from Cerebral Hæmorrhage are less liable to be the seat of occasional cramps or of irregular movements than the limbs paralysed after an epileptiform convulsion or after embolism, and are more likely to be permanently rigid and the subject of pain, referred to the joints on extension.

Suppose, however, the patient remains, let us say two months after the attack, partly paralysed, and that the limbs are in a permanent condition of more or less incapacity. It is very important to bear in mind that we know very little from autopsies, of what becomes of patients whom we have watched to this condition. The patient's
future depends greatly on the mere degree of incapacity. It is a most
unfortunate thing if the leg be so much paralysed that the patient
has to keep his bed, or is fastened to his chair, as it necessarily narrows
mental as well as bodily exercise. I think, judging from a small
experience (autopsies) in this matter, that the comparatively greater
paralysis of the leg points simply to a larger clot in the motor tract.
Inability to get about will lead indirectly to fatty degeneration of the
heart, and thus, even when the kidneys are granular, we must not
expect to find hypertrophy of the left ventricle if the patient has been
kept to nearly one spot for several years.

Treatment.—There is (1) the treatment of the apoplectic condition
which large Cerebral Haemorrhage causes, and (2) treatment for effusion
of blood in nervous tissue. The first may be thought of (a) soon after
the attack, and (b) when secondary symptoms, such as flushed face,
rapid pulse, &c. have come on. The chief point is to be sure of our
diagnosis, and if we are not certain whether a patient is apoplectic or
drunk, or poisoned, we should treat him for drunkenness or poisoning.
The use of the stomach-pump will, it is true, be injurious to a man
with a clot in his brain, and the public—or, perhaps, the public
represented by the coroner, unless of course he be a medical coroner—
is not sufficiently well-informed on medical matters to appreciate
scientific doubts. Still we frequently cannot determine the cause of
the coma, and we must do what is best for the patient irrespective of
all selfish considerations.

The recovery of a patient depends, doubtless, altogether on the
quantity and seat of the sanguineous effusion, and not on our treat-
ment. If the ventricle be opened, if a large clot be in the pons, the
patient will die; but as we cannot be absolutely sure that the patient
has got a clot in his brain at all, we must do all we can for coma,
which may be due (besides drunkenness, poison, and injury) to
uremia, &c. There is, unfortunately, little to be done. The chief
thing is to keep the patient quiet. We should put two drops of
croton oil on the tongue. We should draw off the urine if it did
not pass freely away without help. The application of blisters to
the back of the neck, or of mustard plasters to the calves of the
legs is a common practice, but I know of no evidence to show that
these applications are of service to the patient. Still, in certain
cases of chronic cerebral disease, blisters relieve the patient of severe
pain in the head; and it is not possible to deny that they may be of
service when the circulation of the brain is quickly disturbed after
a clot.Were I to use blisters—I never do—I should only advise
them where there is secondary disturbance of the circulation. It is
hard to believe that mustard plaisters to the calves of the legs can
be of any service or disservice. I never prescribe any medicine
except croton oil by the mouth.

Let us now suppose that the patient was found in, or has passed
into a condition in which the face is flushed, the temperature above
100, the veins prominent, the respiration and the circulation largely
disturbed. In this condition treatment, beyond perhaps purgatives, is of little use. If, however, the pulse be not very rapid, if little more than 100, and if it and respiration be regular, it is not unreasonable to think that the system may be relieved—I do not say the particular lesion would be lessened, e.g. the ultimate size of the clot influenced—by bleeding.

The post-mortem appearances in the bodies of those who have died early—say after twelve hours—of Cerebral Hæmorrhage, usually show great engorgement of every part of the lungs; they are often slaty, black, scarcely crepitate, and break easily under pressure. After a few days there is a difference, and the lung section shows appearances very like those of lobular pneumonia, there being slightly raised, more or less, greyish-red granular looking patches in settings of lung of varying tints of redness. These appearances are not peculiar to Cerebral Hæmorrhage; nor to deep coma, but are, I suppose, the varying appearance of a condition which engorgement initiates. It may be that bleeding from the arm will serve the patient, yet I confess to having no great hope of its being of value to relieve the embarrassment of the venous circulation of the patient, whilst the cause of the embarrassment still keeps its place inside the head. Indeed, my faith is so little that I have never adopted the practice. But we know that a few patients come out of deep coma with embarrassed respiration, and it is possible that bleeding might help more patients out of it. Troussseau, in his admirable lectures, translated by my late lamented colleague, Dr. Bazire, deprecated bleeding in Cerebral Hæmorrhage. Dr. Todd also speaks strongly against the practice. So far as I have observed, however, the practice in this country must be exceedingly rare, as I have in the whole course of my life seen but one person bled for Cerebral Hæmorrhage. Were the pulse very high, e.g. 120, 130, or 150, or if it were irregular, we should not think of venesection.

The foregoing refers to the little that we can do for patients who are in the apoplectic condition. Let us suppose, however, that this is past, or that there has been no unconsciousness, or a very temporary confusion when the hemiplegia indicating effusion of blood has come on. It is quite true that in some of these cases, we are doubtful as to the internal lesion, and not knowing this, our treatment, it is obvious, must necessarily be very general; but when we are confident of the existence of hæmorrhage, we are practically unable to help in the immediate difficulty of effusion of blood in nervous tissue. The more vividly we realise the fact, that a mass of blood is lying abroad in softened and torn nervous tissue, the less confident do we feel in our personal power to interfere. The feeling of helplessness is, I think, greatest, when we are looking at a clot lying in nervous tissue, e.g. in the retina. There is, to speak shortly, to my knowledge, no treatment for effusion of blood in nervous tissue. However, it is quite certain that patients recover satisfactorily from the effects of Cerebral Hæmorrhage. Recovery from hemiplegia follows when the damage to
the motor tract is both permanent and extensive. We should, à priori, suppose that beyond the size, position, &c. of the clot, the younger the patient the more general vigour he has, the more likely will he be to arrive at, or to approach fair health. Certainly when we look at cases superficially, for instance at cases of hemiplegia, we cannot rely on age, general vigour, mode of attack, for circumstances to help us to predict whether the palsy will soon pass off or not. We have still, as in many other diseases, to improve the general health. This is, however, not unfrequently, rather general disease, and the local lesion is sometimes—let us say epistaxis, paralysis for a few days, or a day's thickness of speech—a small matter in comparison with the state of the system of the patient who comes to us for such slight symptoms. The proper care of a patient who has a clot of blood in his brain, and who is liable to have more effused, consists in attending to his diet, excretions, sleeping and exercise. Yet there is nothing in this peculiar to the treatment of Cerebral Hæmorrhage. For the immediate lesion, blood in nervous tissue, I repeat, I know of no direct treatment.
ABSCESS OF THE BRAIN.

By William W. Gull, M.D., and Henry G. Sutton, M.B.

Abscess of the Brain is comparatively a rare disease, and it falls to the lot of no man to see a great many cases. We have collected seventy-six cases in all from various sources, and the details in this paper are based upon these records. Many of the cases have not before been published. We have arranged the different parts of this subject in the following order:—A description of the various conditions that are known to give rise to cerebral abscess, the morbid anatomy, the symptoms, pathology, diagnosis, and treatment.

Suppurative inflammation of the brain may be caused by injury to the head, especially where the skull is fractured and the brain confused. Mr. Prescott Hewitt says:—"All traumatic inflammation of the brain substance may end in suppuration and abscess."

Cerebral abscess may follow a penetrating wound of the brain substance, by a knife, by a splinter of wood, or by some sharp instrument being forced through the skull (Case 74).

Abscess of the brain may follow a fracture of the skull where there is no displacement of the bone; acute suppurative inflammation of the membranes and brain substance being set up by the injury (Case 1). In many cases, caused by fracture of the skull, the abscess in the brain is seated immediately under the injured bone, and close to the surface of the hemisphere. In others the abscess is not seated near the surface; for instance, a person may receive a fracture of the skull, symptoms of compression may set in, and the skull may be, in consequence, trephined; the portions of depressed bone may be removed, and the patient go out of the hospital apparently well. But after a few weeks or months, cerebral symptoms may again appear, and the patient may die; and the autopsy reveal an encysted abscess embedded in the substance of the brain, and seated at some distance from the surface (Case 2).

Cerebral abscess may follow an injury to the skull, where there is no fracture of the latter, and with (Cases 15 and 53), or even without a scalp wound. In such cases the injury excites inflammation and suppuration of the diploe of the bone, and the suppuration extends and involves the brain.
Cerebral abscess may follow contusion, or, as it is sometimes expressed, concussion of the brain, without there being any fracture or other discoverable injury to the skull. Mr. Prescott Hewitt says that he has seen two cases of this kind, and the abscesses were large.\footnote{Holmes' Surgery, vol. ii. p. 185.}

This is a very important class of cases, for it probably embraces not a few of the so-called idiopathic abscesses of the brain.

In two of our cases, abscess was found in the brain, though in neither was there any evidence to show that the skull had been fractured or otherwise injured. With both patients the symptoms followed directly after the injury; one had a fit on the same day as the accident, and the other suffered from almost constant pain in the head for a fortnight after the accident, and was otherwise generally indisposed. The abscesses were encysted in both instances, and, during the time they were forming, there were symptoms indicative of cerebral disease, although, in the second case, the symptoms were, for a while, obscure. One patient died seven weeks, and the other three months after the accident.

Cases might be given to show that abscess may follow injury to the head, without any fracture or other discoverable injury to the skull (Cases 7, 13, 20, 35, 39, 43); and the abscess may remain latent for months or even longer.

One of the commonest causes of cerebral abscess is disease of the internal ear. The clinical history of this class of cases is usually as follows: the patient has a discharge from the ear for some time—for months—and, in many cases, for years; the discharge being continuous or intermittent. It is common to hear it said that the discharge began in childhood, after an attack of measles, scarlatina, or small-pox; and since has returned, more or less. With the discharge there is often deafness and pain in the ear, but more often the patient makes no complaint of either. In some cases, the discharge is very offensive, and has been so for some time past. The extension of the disease to the brain is often very insidious. There may be no indications that the brain has become seriously involved until acute symptoms set in a few days before death. Very often the first sign is a great increase of the pain in the ear. The pain is often very severe, and comes on in paroxysms, so violent in some cases, that the sufferer screams with it. Occasionally the acute mischief in the brain is ushered in with rigors. At other times with nausea and vomiting.

Sometimes an epileptiform convulsion ushers in the acute symptoms, and a few days after this the convulsion is repeated, and followed by hemiplegia.

The accession of acute symptoms, appears, in many cases, to correspond with the commencement of acute inflammatory softening, either primarily in healthy brain, or secondarily, around an old abscess. Then the skin becomes hot, the pulse quick, tongue dry and parched, great prostration, drowsiness and stupor set in. Such symptoms as
resemble continued fever, and have been mistaken for it in some cases. The discharge from the ear varies very much during the acute symptoms. It is common for it to subside, or even entirely to disappear.

Chronic changes, dependent upon diseases of the internal ear, may be insidiously going on in the brain substance, without there being any symptoms of cerebral disease.

Mr. Toynbee was of opinion that the inflammation extends to the brain, from the pus not escaping from the cavity of the tympanum externally. He says: "So long as there is a free exit for the discharge, I believe the disease rarely extends to the brain." He also remarks: "In all fatal cases the discharge has been deprived of a free egress." Mr. Toynbee further states, in cases where the disease attacks the mastoid cells in early life, the cerebrum is the part of the brain which is most likely to suffer, while in later periods of life, the cerebellum is the part most generally affected. Long experience has clearly shown that, when disease of the internal ear has gone on for a long time, the temporal bone is very liable to become diseased. When the patient dies with cerebral symptoms, it is common to find caries of the petrous, or mastoid, portion of the temporal bone. It is also common to find suppurative inflammation of the dura mater covering the diseased bone, with or without sloughing of that membrane. There is, in some cases, no direct extension of the disease from the bone to the contiguous parts. In such cases the bone, membranes, and surface of the brain, are healthy. A portion of healthy brain may lie between the abscess and the bone. The diseased action is considered to extend by a vein. It is rare to find abscess of the brain following acute disease of the ear; but one case is alluded to by Mr. Toynbee.

In cases of chronic disease of the ear, the causes of the acute brain mischief are various. A blow on the head, violent exercise, or other depressing influence; also cold air, or some irritating application, is sufficient to engraft acute changes upon the chronic disease.

Cerebral abscess may be associated with, and apparently dependent upon, chronic disease in the lungs; but in two of our cases the morbid appearances were such as to indicate acute changes in the lungs, extending, however, over several weeks (Cases 9 and 57).

In a case that occurred in St. Bartholomew's Hospital, the lung presented the appearance of acute pneumonia in the third stage; but the symptoms indicated that the disease had been going on about two months and ten days (Case 9).

In all the other cases, which have come under our notice, the morbid changes in the chest had evidently been going on several months and even years (Case 38). In one, there was a large suppurating chronic empyema (Cases 10 and 11). In another, there was a large cavity at the apex of the right lung, which was firmly adherent to the chest walls by a thick layer of indurated tissue.

1 Vide Diseases of the Ear, by Mr. Toynbee, p. 303.
Another patient had had flattening and general contraction of the left chest for years, signs of dilated bronchial tubes, and of disease in the left lung (Cases 36 and 38).

Suppuration in any part of the body may give rise to secondary abscess in the brain. In one of our cases there was an abscess in the sheath of the left rectus abdominis muscle, and several abscesses without cyst in the brain (Case 32). In this case it is instructive to notice that the lungs, the common seat of pyaemic abscesses, did not contain any abscesses, nor were there any in the liver or spleen. In another case there were pyaemic abscesses in the brain (Case 33), apparently the result of chronic suppuration of a mesenteric gland and co-existing recent abscesses in the spleen and kidney. In a case of acute necrosis of the tibia (Case 4), which occurred in St. Thomas's Hospital, there were numerous abscesses in the brain, and pyaemic abscess in the lungs, liver, and spleen. In a case given by Dr. Bright, a whitlow was the source of general pyæmia and abscess of the brain. In another case, referred to by Lebert, the drawing of a tooth was followed by inflammation of the upper part of that face and cerebral abscess. Dysentery was the cause in one instance (Case 25); abscess near the uterus (Case 8); suppuration in the Fallopian tube (Case 75); carcinoma of the face (Case 50); abscess in the liver (Case 51), and the phagedænic ulceration, following amputation of the breast (Case 56), were the causes in other cases. Dr. Ogle relates a case of secondary purulent deposit in the brain, apparently the result of ulceration of the coæcal appendage. There is also another recorded case following amputation of the fore-arm.¹

In chronic disease of the bones of the nose, and in cases of syphilitic disease of the bones of the skull, there is a liability to cerebral abscess (Case 41).

MORBID ANATOMY.—An abscess may form in any part of the brain. Usually it forms in the white substance, and when in the grey it is formed by extension from the white. The middle cerebral lobes are the most frequent seats of abscess. One hemisphere is as frequently attacked as the other. Of 80 cases, abscess was situated in the left hemisphere in 23, and in the right in 29. Practically, therefore, one hemisphere would appear to be as liable to be attacked as the other. In 12 cases abscess was situated in the middle lobe, but it is not stated in which hemisphere. The middle lobes were the seat of abscess in 23 out of 74 instances. Abscess was found in the cerebellum in 13 cases, in the pons Varolii twice, in the corpus striatum twice, in the optic thalamus twice. Abercrombie mentions an instance of abscess in the medulla oblongata. In several

¹From analogy we should expect that an hydatid tumour, or so-called strumous deposit in the brain would cause abscess. We have, however, no record of such a case. Abscess is also said to have occurred when the carotid artery was tied. Probably it was softening of the brain, and not abscess.
of the 74 cases the abscesses were multiple, and found in more than one part of the brain. The appearance of the abscess varies according to its duration. If it have been recently formed the pus is not inclosed in a cyst, but directly surrounded by ragged suppurating brain tissue, and there is not a trace of lining membrane to the cavity. If the abscess have been formed some time the pus is inclosed in a cyst of variable thickness. In very old abscesses the cyst wall has been found a quarter of an inch, or more, in thickness. When the abscess is a few weeks old the cyst wall is usually a line or two in thickness. The wall of the cyst is formed of fibro-cellular elements, and, in some cases, well-formed spindle-shaped fibres are seen; in others the fibro-cellular tissue has undergone granular degeneration, and the fibre cells are very indistinct. The cyst, when of old date, may be divided into three parts—an outer layer, which is made up of loose fine fibrous tissue; a middle layer, which is firmer and more coarsely fibrous than the outer; and the inner surface of the cyst is formed by a smooth, pyogenic membrane, in which some small irregular dilated veins may be seen running in different directions.

In abscesses of recent formation, the pus is generally of a greenish hue, and may, or may not, have a disagreeable smell. In old abscesses, the pus is green, foetid, mucoid, and is decidedly alkaline. The pus removed from old abscesses, when placed under the microscope, shows few or no well-developed pus corpuscles; there is a large quantity of granular fat and granular matter without any nuclei.

There may be several encysted abscesses in the brain. In one of our cases there were no less than four; in another a large encysted abscess in each hemisphere.

The condition of the brain substance immediately around the abscess may vary very much; it has commonly undergone a process of softening. Rokitansky, speaking of recent abscess, says, round the abscess the brain substance is in a state of inflammation, producing red softening, yellow softening, and in more distant partsœdema of the brain tissue.

When a large abscess is situated in one of the hemispheres, the brain is often altered in shape; the convolutions being packed together and flattened; the hemisphere bulged at the side, and if the abscess be very large, the hemisphere containing it may feel more like a bag of pulpy thick fluid than solid brain substance. Collections of pus, in the hemispheres, tend to make their way towards, and discharge themselves into, the lateral ventricles, or on the surface of the brain. Pus, like blood, may fill one lateral ventricle only, or escape into the ventricle on the opposite side. In abscesses, as in very vascular, soft, gliomatous tumours of the brain, hæmorrhagic effusions are occasionally met with, and a coagulum of blood may be seen surrounded by pus.¹

¹ See Guy's Hospital Reports, Vol. iii. 3d Series, Case No. 6, p. 291.
We have already stated that several abscesses may exist together in the brain; this is common when a patient has died of pyæmic cerebral abscess. In such cases every part of the brain may be studded with minute collections of pus; they may be found in the cerebrum, in the cerebellum, in the optic thalamus, in the corpus striatum, and pons Varolii. The size of these abscesses may vary from a pin's head to a hazel-nut, or even larger. They are usually situated near the surface of the brain. The cerebral substance around these pyæmic abscesses may be softened, at other times it is firm and comparatively healthy. When abscess of the brain is dependent upon disease of the internal ear, the morbid appearances are much as follows: the dura mater, situated over the diseased petrous or mastoid portion of the temporal bone, is often found highly congested, softened, and ulcerated. Or of a dirty green colour, and evidently 'sloughing, and the bone laid bare. In other cases the dura mater is simply thickened and covered with purulent lymph, and betwixt the dura mater and the bone there is often a collection of pus. The lateral sinuses are frequently involved and plugged, especially when there is disease of the mastoid cells; the sinus is often seen enveloped in pus and purulent lymph. The suppurative inflammation may extend along the internal jugular vein, and set up suppurative pleuritis and abscess in the lung.

In abscess of the brain due to disease of the ear, there is, in the majority of cases, caries of the temporal bone; the latter is seen of a dark colour, with an irregular roughened surface. The abscess in the brain may have direct communication with the diseased bone, and the contents of the abscess make their way through the ulcerated openings in the dura and bone into the tympanum, and then escape through the perforated membrane tympani into the external meatus, thus constituting what has been termed "otorrhoea cerebralis." A similar communication and escape of the pus is said to have occurred in cases of abscess in the brain caused by diseased ethmoid bone. At other times there is no such direct communication, for there is a layer of brain substance separating the abscess from the membrane of the brain. This layer is often softened, of an ash grey, or yellowish appearance, and looking as if the pus was about to burst and discharge itself on the surface of the brain.

In some cases of abscess dependent on disease of the internal ear, there is no caries of the bone, as we have already mentioned, the membranes may be healthy, and the abscess may be situated at a distance greater or less from the surface of the brain.

**Symptoms.**—In 73 cases of abscess of the brain, the symptoms were as follows:—Pain in the head in 39 cases; epileptiform seizures in 38; coma in 30; heaviness, stupor, and drowsiness in 30; paralysis in 24; rigors in 17; pyrexia in 13; delirium in 13; vomiting in 12; incontinence of urine, or of feces, or both, in 15; vertigo in 8; disordered sensibility, not including pain in the head, in 6; defective articulation in 4; defective sight in 3; an apoplectic attack in 1.
That some of the symptoms may have existed in greater proportion, we should be prepared to expect, especially such symptoms as vertigo, pyrexia, emaciation, and probably in a greater number of cases, defect of sight would have been discovered had the eye been tested. The symptoms, therefore, that are most frequently observed in cases of abscess in the brain are pain in the head, epileptiform attacks, paralysis, coma, heaviness, drowsiness, stupor, rigors, pyrexia, delirium, vomiting, and incontinence of urine and feces. In a few cases defective articulation was met with. The records show that the intellect was very little affected. Paralysis was observed in 24, that is in about one-third, whereas in Lebert's cases it was observed in about one-half. He included, however, not only local paralysis, but also general loss of muscular power, whereas we have confined the term to local paralysis only, such as loss of power on one side of the body, of one arm or leg; one side of the face, or some other part.

The first symptom, in many cases, is pain in the head; it may be the only indication of cerebral disease present for months. The pain is often very agonizing.1

An intense neuralgic pain situated over one spot is occasionally the first symptom; sometimes the pain is seated almost immediately over the region of the abscess. A boy having an abscess in the anterior lobe of the right hemisphere, complained of almost constant burning pain over the front and right side of the head, but this localization of pain over the seat of the abscess is by no means constant. In some cases the pain is very remote. In one patient there was an abscess in the cerebellum, and the pain was felt in the forehead; in another there was an abscess in the right middle cerebral lobe, and the pain was referred to the left side of the head.

The pain often comes on in paroxysms; in other cases it is continuous, remittent, or intermittent. It is not present in all cases of cerebral abscess, as the statistics of our 76 cases show. It is very commonly associated with pain in the ear, when the abscess is due to disease of the auditory apparatus. Instead of pain preceding, it may follow the convulsive attacks. Cases of this kind are by no means few.

Occasionally the first indication of cerebral mischief is a sudden and unexpected epileptiform seizure. The epileptiform seizures are occasionally the most prominent symptoms from the time of seizure to the patient's death. The epileptic attacks do not necessarily come on every day; occasionally some days elapse between the seizures. After each convulsion the side affected is often left weak, and this increases until there is complete hemiplegia. The convulsive move-

1 One patient lay in bed continuously holding his head with both his hands; another walked about with his hands pressed against one side of his head, crying out constantly, "Oh! my head; oh! my head." The pain is often so severe that the patients shriek not from the agony they suffer. A patient, who was perfectly sensible, said he could not help screaming; and, although he tore and bit anybody or anything near him, he at the same time expressed contrition for what he was doing, and said the pain in his head was unbearable; it felt as if some one was knocking it with a hammer.
ments are sometimes unattended with insensibility, and are confined to one extremity, especially the arm. This had been long noticed.

Abercrombie alludes to a case of Lallemande's, in which there was pain in the right side of the head and tremor of the left arm. This was followed by continued convulsions, flexion, and extension of the left arm, which after some days ended in palsy.

Instead of convulsive movements, the first indications of brain disease may be numbness and tingling in one extremity.

The symptoms in other cases of cerebral abscess are like those that are said to indicate cerebral softening. There is sudden loss of power on one side of the body without any loss of consciousness; the leg being less affected than the arm.

In several instances rigors were very prominent symptoms throughout the attack. A patient, suffering from suppuration, was noticed to be getting thinner and weaker; when he was seized with rigors, diarrhœa, a dry brown parched tongue, and a hot skin, he became comatose and died. Pyæmic abscesses were discovered in the brain.

In some cases of pyæmic abscesses, there are no special symptoms to show that organic disease is going on in the brain; but only the general indications of pyæmia. In others the accession of convulsive seizures, paralysis, or coma, indicates disease in the cerebral organ. Rigors so severe were noticed in a few instances, and returned with such regularity every day, that they closely resembled those of ague. One patient had headache, rigors, and vomiting, returning every day for five days, and then became unconscious. Rigors do not occur, in some instances, until after convulsive seizures have indicated cerebral mischief. Imperfect articulation, to a marked degree, was noticed in some cases, and in one there was loss of language.

With respect to the eye, Dr. Hughlings Jackson has mentioned to us that he has seen changes in the retina (optic neuritis?) in a case of cerebral abscess. Dr. Jackson thinks such changes are common to several kinds of cerebral disease.

Mental disturbances were observed in some cases. Now and then, the only symptoms noticed were a heavy expression, a disinclination to speak, and indifference to surrounding objects. In some cases with disease of the ear, it was stated that the patients had attempted to commit suicide. One patient appeared to become hypochondriacal. Emaciation setting in rapidly was a marked symptom in several cases. Similar emaciation is seen in some cases of tumour of the brain; but is not so frequent as in abscess.

Patients suffering from cerebral abscess may have symptoms so closely resembling continued fever, that it is exceedingly difficult, if not impossible with any degree of certainty, to say whether it be a case of fever or of organic disease of the brain.

Pathology.—Cerebral abscess may be produced by direct injury, or by contre-coup: contusing or lacerating the nervous tissue, and setting up inflammation and suppuration. It may be produced by suppurative
inflammation in some tissue in the neighbourhood of the brain which spreads to a contiguous part; namely, in the ear or nose, which extends, and invades the dura mater, pia mater, and brain substance. Or the diseased action may spread by continuity of structure, as along a vein, and thus to the brain. Disease of the ear, nose, or of other cranial bones, may give rise to cerebral abscess in this manner. Again, abscess may be produced where there is disease of the cranial bones, or some growth involving them, by the veins communicating with the diseased bone becoming plugged. The process of coagulation extends and invades the veins communicating with the sinuses of the dura mater. These become plugged, as also the veins of the pia mater and probably some branches entering the brain tissue also, and inflammation, terminating in suppuration, is thence set up in the brain. In other cases, minute coagula, or thromboses, are supposed to be detached and carried along by the circulation until they are arrested in the capillaries of the brain, and often of the lungs, kidneys, and other organs.

Pyæmic abscesses are occasionally found in the brain, and not in any other organ of the body. Besides the coagula, some of the elements of pus may be carried by the circulation to aid in, or be the means of, setting up suppuration in the parts where the thrombosis is arrested. In this way abscesses in the brain are probably caused by abscess or suppuration in the liver, lungs, bowels, or in other parts.

We next inquire if every form of cerebral inflammation, or encephalitis, no matter what its origin, be liable to end in suppuration and an abscess. It has been many times stated that such is the case; but it would appear that the inflammation must be set up by a special cause, and unless it be so, it does not end in suppuration and abscess. Suppuration may apparently be excited by local injury, or by the elements of pus or thrombosis; but experience shows that other forms of inflammation do not terminate in abscess. For instance, encephalitis and softening, the result of plugging of a cerebral artery, or encephalitis around a haemorrhagic effusion, or around a gliomatous tumour or old cyst, shows no disposition to the formation of pus or abscess. The brain may soften, disintegrate, and a cyst may be formed, but there is no pus formed.

It is necessary, now, to ask if there be not good evidence to show that the brain may be the seat of suppurative inflammation and abscess without there being any cause to account for it? Is there not, in such cases, idiopathic inflammation which gives rise to idiopathic abscess? By idiopathic cerebral abscess, we suppose, is meant abscess which is not preceded or occasioned by injury or disease; its origin being unaccounted for. Lebert and others admit the occurrence of idiopathic cerebral abscess. Such cases are, however, in comparison with others, rare. It is beyond all doubt that a certain number of cases of cerebral abscess do occur in which no disease is discovered in any other part of the body, and there is no history of any recognised cause to account for the cerebral abscess.
Before, however, it be concluded that abscess has been formed idio-
pathically, it is necessary to remember that in the majority of cases
there is a cause to account for the formation of such abscess, and that
only in a very small minority have observers failed to find some
admitted cause. In the face of such evidence, is there not good
reason to think that, in this small minority of cases, the primary cause
has been overlooked. And, when it is still further remembered that
hours have been passed in searching for the primary disease or cause,
and at last it has been found limited to a mesenteric gland, a gum-
boil or a whitlow—in fact the primary disease was so small, that it
might have been very easily overlooked—it appears to us not difficult
to understand how, even after very great care, the primary cause may
have remained undiscovered. Bearing all this in mind, we recognise
that in a few cases of cerebral abscess, the cause cannot be dis-
covered; but even when the cause is undiscovered, we should not
assume that the suppurative inflammation has commenced idiopathi-
cally in the brain.

Cerebral abscess proves fatal in many cases, not by a collection of
pus in one or other part of the brain, but by extensive inflammatory
softening around the abscess, involving vital parts of the brain; and
it is from such softening that the abscess is enabled to make its
way towards the ventricles or the surface of the brain. The soften-
ing around very old encysted abscess would appear not to be set up
by pyogenic changes going on in its lining membrane, for there is not
a large quantity of well-formed pus corpuscles in old encysted
abscesses to show that such active changes have been going on in this
membrane.

The softening would rather appear to be due to some circumstance
interfering with the nutrition of the parts outside of the abscess, but
in its neighbourhood. The nutrition of such parts, owing to the pre-
sence of a foreign body, being very feeble, it is easy to understand how
a blow on the head or a debilitated or cachetic state of the system
may be sufficient to excite such feebly nourished parts to take on
acute inflammatory softening.

Has abscess in the brain any tendency to spontaneous cure? Lebert
thinks not, and when we remember that there is no well-established
case on record, showing that an abscess has been spontaneously cured,
we readily admit that the evidence very strongly favours the belief that
cerebral abscesses do not tend to a spontaneous cure. It is, however,
necessary to remember that the brain is a very vital organ, severely
taxed in our every-day labours, and, if not sound, its functions,
which are essential to life, may be brought to a stop. When there is
an abscess in the brain, the organ being unsound, its functions are very
liable to be perverted, and death follows; whereas, if the abscess were
seated in an organ less essential to life, any perversion of its func-
tional activity would not be attended with fatal results, and thus
time would be gained for the abscess to pass through the different
stages essential for its cure. We may therefore ask ourselves whether
it is that an abscess of the brain has no disposition to spontaneous cure, or whether it is that the patient does not live long enough for such a process to be accomplished? The development of a firm cyst wall would show that there is a disposition to spontaneous cure. The cyst wall is a protective effort that the brain makes to localise the mischief and protect the sound from the diseased part. And experience has shown that time is only required for such protecting efforts to be very great, and for the barrier guarding the pus to become stronger and stronger.

We are next led to ask, is there any thing in the condition of the pus discovered in old abscesses to show that these were in a process of cure? To our minds, there is. It is usual to find such pus in a very degenerate condition, viz. granular and fatty, which is favourable to its absorption and concretion: such changes as occur in abscesses that have undergone spontaneous cure. This is no idle question. It is simply—Is cerebral abscess necessarily a fatal and incurable disease? Practically it is, but there is nothing in its morbid anatomy to lead us to conclude that it is necessarily incurable.

**Diagnosis.**—Cerebral abscess is inferred when there are symptoms of the brain indicative of organic disease, and there are present those morbid conditions that are known to give rise to cerebral abscess, such as a discharge from the ear, nose, or chronic suppuration elsewhere, or when there is a history of a blow, or of some other acknowledged cause of the disease. No doubt that in some cases the inference proves correct, where there is evidence showing that the cerebral substance is undoubtedly diseased, and further evidence of suppuration going on in some part of the body; for here there are indications of acute brain disease, and we are led to suspect that this is due to abscess, since such causes are present as are known to produce it. With the brain, however, as with other organs, we are more often able to say that it is diseased than to say what is the precise nature of the pathological changes going on in its substance.

There may be evidence to show that a patient has chronic disease of the nose or ear, and cerebral symptoms may supervene suddenly; epileptiform seizures and other symptoms may be present, such as are seen in cases of cerebral abscess; the patient may die and yet there may be no disease of the brain or of its membranes. In some cases, the membranes alone are diseased; in others, the brain substance is softened, without abscess. Disease of the bones of the skull, no matter whether it be fracture, syphilitic disease, or a growth, is liable to set up inflammation of the membranes of the brain, and the inflammation may spread and give rise to suppurative inflammation of the brain substance. If the patient survive six or seven weeks, an abscess may be formed; if he die in two or three weeks after acute symptoms have set in, the brain may be found softened, but without abscess. Not unfrequently death takes place before there is time for the suppurative inflammation to form an abscess.
ABSCESS OF THE BRAIN.

There may be a history of injury to the head, cerebral disease may appear to have followed as a consequence, and the post-mortem examination reveal disease in the brain, but not abscess.

Injury may be followed by the formation, not of an abscess, but of a tumour, malignant disease, or by softening in the brain; or further, the disease may not be in the brain at all, but on the surface. Experience has shown that an injury to the head may produce a large cyst in the cavity of the arachnoid, and the symptoms of the case may be similar to what are seen in cases of encysted abscess.

A history of a blow on the head, followed by severe pain, loss of energy, altered manner, fits, and partial hemiplegia, occurs in abscess, but also in other cerebral diseases as well as abscess.

Cerebral symptoms associated with offensive discharge from the ear and nose, would lead one to suspect abscess in the brain, but in one of our cases there was tumour, and not abscess. The co-existence of tumour in the brain with the conditions that are known to produce abscess, makes the differential diagnosis extremely difficult. There are no pathognomonic symptoms of abscess nor of tumour. It is only the different manner in which the symptoms are grouped, and the existence of those conditions that are known to produce one and not the other disease, which leads the practitioner to suspect that there may be tumour rather than abscess, or vice versa.

The symptoms of abscess may differ from those of tumour in the following respects. In abscess there is often marked cachexia and great emaciation. In tumour, the patients have often no marked cachexia, even look healthy, and the body is fairly nourished, certainly not emaciated. In abscess the duration of the cerebral symptoms is generally much shorter than in tumour——The symptoms in abscess are usually either latent or acute; in tumour they are often chronic. In the latter there may be local paralysis extending over several months, which is very rare in abscess. The intra-cranial nerves are much more frequently affected in tumour than in abscess. Occasionally, however, a person with tumour is seen to be much emaciated. These differences may enable the practitioner, in some cases, to diagnose one condition from the other, but in neither case are these differences so constant that a certain diagnosis can be made.

An abscess may lie latent in the brain for many months, and then acute symptoms may suddenly set in, and the patient die in a few days. The same thing may take place with respect to cerebral tumour. Experience has shown that cancerous deposits also may exist in the brain without there being any decided cerebral symptoms.

Chronic encysted abscesses and tumours of the brain have many symptoms in common. An hydatid tumour; gliomatous tumour; a cyst; cancerous deposits in the brain, or any other substance acting as a foreign body, may produce pain in the head, epileptiform seizures, with or without paralysis, optic neuritis, vomiting, or gradual loss of muscular power.

We are often able to say, when there is acute persistent but variable
paralysis, with pyrexia, that there is acute inflammatory softening of
the brain; but whether that softening is going on around an abscess,
a tumour, or a cyst, or whether excited by disease situated on the
surface of the brain, we may be unable to give any exact opinion.

With respect to rigors in cases of cerebral abscess, we have already
stated that they are very well marked in some instances, and may
be not unlike those of ague. This symptom is not, however, peculiar
to cerebral abscess. It occasionally occurs in other forms of brain
disease, for instance, as gliomatous tumours or tubercle.

**Treatment of abscess of the brain should be, by anticipation,—**
obviating the causes which lead to it; in chronic disease of the
ear or nose, by maintaining a free exit for the discharge, no matter
what the exciting cause. Rest is the most important part of the
treatment, avoiding thereby both mental and mechanical excitement.

By a simple diet and quiet life, abscess may be dormant in the
brain for an indefinite time.¹

In cases where abscess follows injury to the head, surgical inter-
ference must be thought of. The principle in such cases is a me-
chanical one, namely, to reach the abscess and evacuate its contents,
if that be thought advisable,—experience has but little to com-
mend it.

¹ This is, however, to be observed that encysted abscess of the brain is fatal from
changes, outside the cyst of an acute kind, such as might be presumed to be preventible
to a great extent. In support of this opinion we may say that, in our experience, we
have known abscess lie quiet for months after a blow on the head, and the patient and
the medical attendant become confident that all was well; the symptoms of lesion
having slowly gone off, and yet a fatal issue be produced after a few hours' suffering by
neglecting the precaution of rest and regimen. Probably such rest and care should be
continued, not for months only but for years. This we say from clinical observations of
the changes in the cyst of old cerebral abscess.

</table>

Paroxysms of extreme restlessness. Cerebral oppression. Death on the 17th day. No convulsion nor paralysis throughout.

Paralysis of right seventh nerve, and discharge from the ear, and headache after a blow. After three weeks headache increased, referred to forehead and occiput. Pain on moving the neck. Rigors, nausea, vomiting, sweating. No delirium. Death from syncope on the 4th day after the increase of the headache.

Sudden lightness in the head, followed, after a short interval, by convulsion and insensibility, recovery, and a second convulsion the same day. On the 3rd day headache, increasing to great intensity on the 5th; referred to the right side of the forehead, right temple, and occiput. No delirium. Death on the 8th day, in coma.

Langor for some days. Syncopal seizure. Convulsions with insensibility, relieved by a discharge of pus from the right ear. Following day severe headache from the forehead to the vertex. Nausea. Delirium at night, 6th day, return of convulsions, with insensibility. Intense pain and cramp in left leg. Death in rather sudden coma, 15th day.

Epileptiform convulsion, followed by apoplectic symptoms lasting several hours. Only partial recovery of memory after ten days. On the 14th, vomiting; increased cerebral oppression. At beginning of 4th week sank into sudden coma, with paralysis of right side. Death on 26th day.

Abscess in cerebellum. Inflammation of the vein of the aqueductus vestibuli. About twelve days.

Acute abscess in middle lobe of cerebrum on the right side. Eight days.

Abscess, containing about an ounce and a half of pus under the posterior lobe of right hemisphere of the cerebrum, between it and the tentorium. Caries of petrous bone. Fifteen days.

Undefined abscess in posterior lobe of cerebrum, on left side. Twenty-six days.

<tr>
<td>46</td>
<td>Male</td>
<td>16</td>
<td>Compound fracture of right parietal bone of the skull.</td>
<td>Fell eleven feet. Admitted half stupor. Capable of answering questions. Scalp wound, and depressed fracture. Hernia cerebr. No pain on admission. Slight pain came on later. Tongue became white. Incision was made into the wound. Much discharge, mixed with brain substance. Went on well until 14th day, when suddenly became unconscious. Stertor. Dilatation of the pupil. Pulse fell fifty-two, and he died.</td>
<td>Fracture of the right parietal bone. Between dura mater and bone, flakes of coagulated blood. Corresponding to this, recent fibrin; on breaking through it a large quantity of creamy pus, escaped from an abscess so large that it passed into the anterior and posterior lobe of the hemisphere. All of the outer part of the middle lobe destroyed. Separated from the lateral ventricle only by the lining membrane. Brain elsewhere natural.</td>
</tr>
<tr>
<td>48</td>
<td>Male</td>
<td>44</td>
<td>Scalp wounds. Arachnitis.</td>
<td>Pulled to the ground, and three or four scalp wounds produced over the right part of the forehead, penetrating to the bone. Went on well. In a day or two outer surface of cranium roughened. Pus between dura mater and bone, opposite one of the scalp</td>
<td>Died on the 18th day of admission.</td>
</tr>
</tbody>
</table>

While drunk sustained a compound fracture of the occipital bone. Headache; restlessness; slight want of power in the muscles of the right side of the face. Pupils dilated. Went on the same until 16th day, when seized with twitchings of the muscles of the face. Coma set in, and he died on the 16th day of admission.

Upper surface of both hemispheres smeared over with blood; white portion of the right anterior lobe bruised, and between it and the surface of the brain, an abscess near the orbital plate of the ethmoid bone. Pia mater thickened and congested. Lateral ventricles distended with purulent fluid, and lining opaque. Recent lymph in sub-arachnoid spaces.

During the whole of his disease there were no symptoms to indicate brain disease.

Ulcercation and perforation of the sphenoid bone and dura mater. Adjoining this, near the convolutions an abscess in the substance of the right cerebral hemisphere, and it had contained a large quantity of pus which had escaped through the apertures in the dura mater and bone.

No mention of abscess elsewhere. Idiopathic?

On February 23rd, previously in good health, he was seized with hemiplegia of the left side. No loss of consciousness. Sensibility of skin not much affected. On admission, left arm most paralysed. Paralysis left side of the face. Pain in the head. Under treatment he improved. Recovered somewhat the use of his arm. 25 days after admission, rigors set in—shook like a person in ague—followed by a fit and coma. Died next day.

Admitted August 31st. September 8th she had an apoplectic attack, followed by coma. Loss of power in the right arm and leg, and left side of face. Difficult articulation. The arm partially recovered. Bed-sores came on, and she died December 1st, that is, 53 days after the cerebral symptoms set in.

Sub-arachnoid tissue infiltrated with pus. A circumscribed, encysted abscess above the roof of the right lateral ventricle. Cyst wall was one-twelfth of an inch thick. Contained greenish fetid pus. Surrounding brain softened. Lateral ventricles filled with pus.

The left optic thalamus contained a quantity of purulent deposit, very much softened, to the extent of a threepenny piece, of an ochre colour. Left corpus striatum and neighbouring parts of the brain extensively softened. An abscess behind the Cecum; the latter ulcerated.

Several abscesses in the substance of the brain. Two in the right hemisphere, about an inch from the surface. A largeish one in the centre of the left hemisphere; also two smaller ones. Abscesses in the left hippocampus major, left optic thalamus, and cerebellum. An abscess in the right lung.

left cerebral hemisphere, middle lobe, lined by a false membrane; contained dirty green pus. Surrounding brain softened.

Six weeks before admission, subject to boils. Two weeks before admission, pain in and purulent discharge from the right ear. Three days before admission she became delirious. When admitted, great maniacal excitement; obliged to be confined in a strait jacket. Three days afterwards, slight attack of opisthotonos. Retention of urine. Incontinence of faeces. Sank into coma, and died.

A second fit seven days afterwards. Left him with pain and discharge from his ear, and passing his motions involuntarily. Been "silly" since the fits. On admission, paralysis of the left upper eyelid. Mouth drawn to the left, and tongue turned to the right. Limbs all weak, but perfect power over them. Complained of nothing but of twinges of pain in his left ear, and deafness. Articulation imperfect. Became dull and drowsy. Semi-comatose. Then a convulsive attack. Coma. Several fits followed. Coma, involuntary evacuations, and death.

Vomiting. Purulent fluid in the right arachnoid. Convolutions generally flattened. Brain throughout softened. In ventricles, six ounces of semi-purulent fluid. Lining membrane vascular. Septum lucidum quite destroyed. Fornix diffusent. Under surface of the middle cerebral lobe ash-grey colour. In it an abscess size of walnut, lined by a thick cyst of organized lymph, and containing 1 oz. of milk-white pus. Fibrinous exudation between the surface and the bone; the latter slightly diseased and having an aperture leading to the tympanum, the latter ulcerated, full of pus.

Fifteen days before death. Recorded by Dr. Ogle.

Caries of the mastoid cells. Polypi in the external meatus.

In June, 1851, suffered from so-called simple fever. He had severe headaches, chiefly in the right temporal region, and discharge from the right ear. Pain never entirely left. 12th, pain increased. His speech became thick and indistinct, at times almost unintelligible. No fever. 13th, he dragged his right leg. Vomited and became drowsy. 16th, vomiting and drowsiness continued. Had occasional double vision. 17th, decidedly improved. 19th, able to come down stairs. July 2nd, symptoms returned with greater violence than ever. Vomited frequently. Intolerance of light. Mind clear. July 7th, again improved. Pain, drowsiness, and sickness diminished. 13th, much improved. 15th, again he became worse. Severe paroxysms of pain, followed by stupor. He died in one of the paroxysms, July 17th.

Abcess in the right lobe of cerebellum, containing fetid pus. Ulceration of dura mater, over a carious portion of the temporal bone.

The under surface of the right lobe of cerebellum attached to the dura mater. Three abscesses in this lobe. Two lined by distinct membrane. Almost the whole of this lobe was a bank of pus.
No. | Sex | Age | Cause. | Symptoms. | Seat of Abscess.
---|---|---|---|---|---
74 | Male | 4 | Injury to the head. A splinter of wood had penetrated the skull. This occurred on Oct. 1, 1864; he died Oct. 27, 1864. | Suffered from the effects of the explosion at Erith, and received a penetrating wound of the skull by a piece of wood. A splinter had been driven in. It was removed, and becoming worse he was removed to Guy’s Hospital. Mr. Cook made an incision. Some pus escaped, and after the pus some clear fluid followed. The child appeared relieved, and went to sleep, soon got worse, and died three days afterwards. | Autopsy showed an oval opening in the skull at the back part of the head on the right side. Acute arachnitis on both sides, more on the right. An abscess, the size of a walnut, in the back part of the right hemisphere, just below the descending cornua; purulent matter also in the lateral ventricle. The clear fluid that escaped was probably ventricular.

75 | Female | 31 | Tubercular disease of the lungs, Fallopian tube, and uterus. | Two weeks before admission into Guy’s Hospital she came one day as an out-patient, with a “wet rag” on the top of her head. She complained bitterly of the pain in her head. Her tongue was furrowed, and she had some pyrexia. Thinking it might be fever, she was ordered salines, and advised to come into the Hospital. About eleven days afterwards she came again, and “still had the rag on her head,” and complained very much of pain in the head. This was her principal symptom. | Post-mortem examination showed no disease of the bones. A small tumour attached to the surface of the dura mater, imbedded into the edge of the hemisphere, near the longitudinal sinus. Vascular arachnitis. On surface of brain a thick cyst the size of a grape, and filled with liquid pus. In the brain substance, there were three abscesses exactly like it. Each had a thick cyst, which was vascular, and could be easily turned out. All close to the surface. All the size of small clews. Lungs filled with tubercular matter. Fallopian tube near its end filled with a soft tubercular and purulent matter; also the uterine, near the opening of the tube.

76 | | 35 | Cause unknown. Had he had any blow on the head? The so-called fainting-fits’ evidence tended to show some long-standing cerebral affection? | Led an irregular life. Employed at a music hall, and some years ago got his chest crushed in an accident, and said after the injury that he spat blood. Not known that he had injured his head. All that could be learnt of any previous illness was that he had been subject to “fainting-fits.” Said to have been well until three days before admission, when he was seized with tingling and numbness in the left hand; this increased, the arm got weak. On admission, much loss of power on the left side; this increased. A week before he died, complete hemiplegia. Twitching on the right side. Became insensible and died. | Post-mortem examination:—Calvarium was irregularly thickened in parts, as if there might have been an ostitis at some previous time, but no eardis was discovered. Arachnoid slightly greasy and opaque. A large abscess in the left hemisphere, with a distinct wall, evidently some weeks old. It contained offensive viscid yellow pus. Had opened into the left lateral ventricle. Lungs congested. Heart, liver, kidneys, bladder, spleen, peritoneum, all healthy.

* The last three cases are recorded in Guy’s Hospital Post-mortem Records. Dr. Wilks has kindly allowed us to make use of them.
B. Partial Diseases of the Nervous System (continued).

2. Diseases of the Spinal Column.

DISEASES OF THE SPINAL CORD.

BY C. B. RADCLIFFE, M.D., F.R.C.P.

A. PRELIMINARY REMARKS.

Before proceeding to cope with the intricate and difficult pathological topics which form the subject of the present article, it appears to be expedient to glance at some points in the physiology of the spinal cord, and also to try and ascertain the true significance of pain, spasm, and certain symptoms analogous to pain and spasm, which figure conspicuously in the histories of spinal maladies; for if these matters be not disposed of as preliminaries now, they will prove to be the cause of frequent and distracting digressions afterwards.

1. A glance at some points in the physiology of the spinal cord.—The result of recent researches has been to establish in the fullest manner the truth of Sir Charles Bell's great discovery, that the posterior roots of the spinal nerves are devoted to sensation only, and the anterior roots to motion only. In one article, at least, the creed of to-day is the same as that of yesterday: and it is some comfort to have it so, for in many other articles faith is not a little shaken by the changes of belief which are now found to be necessary.

The view once held that the posterior columns of the spinal cord are made up of bundles of fibres passing from the posterior roots of the spinal nerves to the sensorium has proved to be untenable. Transverse division of these columns produces in the parts behind the section, not numbness, as it would do if these columns were simply the continuation of the posterior roots of the spinal nerves, but hyperesthesia: and the pain resulting from the section is found to be due, not to any sensitiveness in the columns themselves, but to the irritation having extended to the posterior roots of the spinal nerves. Transverse division of these columns produces in the parts behind the section, not paralysis, but loss of co-ordinating power, such as is seen in locomotor ataxy. Moreover, the researches of Mr. Lockhart Clarke prove very clearly that the filaments, comparatively few in number, which go from the posterior roots of the spinal nerves to the posterior columns of the cord, do not end in those columns, but pass through them to the part to which the other and more numerous filaments composing the roots pass directly,—that is, to the central grey matter of the cord; and thus it is not difficult to see why the
posterior columns can be cut across without benumbing the parts behind the section—why a result should follow which would not be possible if those columns were the continuation of the posterior roots of the spinal cord.

All that has been said of the posterior columns of the cord appears to apply equally to the restiform bodies—to the bodies which form the chief connexion between these columns and the cerebellum, and not to those bodies only, but also to the small posterior pyramids of the medulla oblongata, which pyramids lie between the restiform bodies posteriorly. The connexion between the cerebellum and the posterior columns of the spinal cord, which is made by means of the restiform bodies, is indeed such as to make it not improbable that the posterior columns perform for the cerebellum a similar office to that which is performed for the cerebrum by the anterior columns, or, in other words, that the posterior columns do for the involuntary movements of co-ordination what appears to be done for voluntary movements by the anterior columns.

The anterior columns of the spinal cord have, without doubt, a special connexion with the anterior roots of the spinal nerves, and an all-important part to play in voluntary movement; and yet this cannot be said of them, as was formerly supposed, in every part of their course. The power of voluntary movement on the same side of the body, in the muscles behind the section, is altogether destroyed when one of the anterior columns is cut across, unless the cut be in the part which lies immediately below the anterior pyramid of the medulla oblongata; and the same result happens when the adjoining lateral column is cut across where it lies side by side with that part of the anterior column which may be cut across without giving rise to paralysis. It is plain, in fact, that in the uppermost part of their course the anterior columns have not that intimate connexion with the anterior roots of the spinal nerves, and that all-important part to play in voluntary movement, which they evidently have everywhere else. And it is also plain that the anterior columns have somewhat to do with sensation as well as with voluntary motion, for it is a fact that a certain degree of numbness is always produced by the injuries which give rise to paralysis.

A transverse section of one of the anterior pyramids of the medulla oblongata in any part of its course annihilates all power of voluntary movement in the muscles behind the section on the opposite side of the body; and thus it is plain, not only that each pyramid contains very many, if not all, the conductors concerned in carrying the orders of the will to the muscles of the opposite side of the body, but also that the conductors which are collected in one pyramid decussate with those collected in the other pyramid at the lower and not at the upper boundaries of the pyramids. If anaesthesia be the result of cutting across the anterior pyramids of the medulla oblongata, its amount is too small to be unequivocal; and, in a word, all the evidence, old and new, goes to show that these bodies are composed
of conductors concerned in voluntary motion without any admixture of sensory conductors.

The office of the lateral columns of the spinal cord is not so clearly made out as that of the posterior and anterior columns. In the cervical region, for a short distance below the point at which the anterior pyramids of the medulla oblongata intercross, the lateral columns of the spinal cord have certainly very much to do in transmitting the orders of the will to the muscles; for, as has just been seen incidentally, the muscles behind the section on the same side of the body are paralysed by cutting one of them across. In the lower part of the cervical region, and in the dorsal and lumbar regions, it is very different, and the difference is not very clearly determined. Here some trifling paralysis may be produced by dividing these columns transversely, but never more than this. Here, indeed, it would seem that this operation is followed by a certain degree of anaesthesia, and by the same result, as regards movement, as that which follows transverse division of the posterior columns—that is, not by paralysis, but by in-coordination. A certain degree of anaesthesia appears to be a constant consequence of cutting across the lateral columns in any part of their course; and herein would seem to be an important distinction between the lateral and the posterior columns, for, as has been stated already, the result of cutting across the posterior columns is to produce hyperaesthesia, not anaesthesia.

A section of the olivary bodies is followed, not by any marked degree of paralysis, or anaesthesia, but by a state of persistent spasm in many muscles on the same side of the body, in the neck especially—a state which may sometimes continue for days, weeks, or even months. It is found, also, that this strange result is produced by irritating several parts of the base of the encephalon, the lateral and posterior parts of the medulla oblongata and pons Varolii especially, as well as by irritating the olivary bodies. These parts are not very clearly defined. "They seem," says Dr. Brown-Séquard, "to be quite different from those employed in the transmission of sensitive impressions, or of the orders of the will to the muscles, at least in the medulla oblongata and pons Varolii. They constitute a very large portion of these two organs, and, perhaps, as much as three-fourths of the one first named. They are placed chiefly in the lateral and posterior columns of these organs; and because many of their fibres do not decussate, the spasm produced by irritating them is on the same side of the body."

Instead of being merely a nerve centre—the special centre of Marshall Hall's excito-motor system of nerves—there is now reason to believe (as Dr. Brown-Séquard has so clearly shown), that the grey substance of the spinal cord is an important conductor of sensory and motor impressions. Paralysis without loss of sensation on the same side of the body, loss of sensation without paralysis on the other side of the body, are the strange results of cutting across one lateral half of the grey substance of the spinal cord: anaesthesia on
both sides of the body, paralysis on neither side, are the equally strange results of making a vertical section midway between the two lateral halves: these are the two great facts which, when properly interpreted, furnish the reasons for believing, not only that there are sensorial and volitional conductors in the grey substance of the cord, but also that these two forms of conductors follow a different and definite course. Nor is it difficult to see how this may be. Let the course of the conductors in connexion with the anterior and posterior roots of a pair of spinal nerves be what is represented in the following diagram,—a b being the motor conductor descending to the right, and a' b' the corresponding conductor descending to the left; c d being the sensory conductor ascending from the left, and c' d' the corresponding conductor ascending from the right,—and very little reflection will serve to supply the demonstration wanting. With the sensory and motor conductors arranged in this manner, it is plain

![Diagram](image)

that a cut across the right lateral half of the grey substance—a lesion indicated in the diagram by the line A B—must destroy the continuity of the motor conductor a b, and of the sensory conductor c d, and leave untouched the motor conductor a' b', and the sensory conductor c' d'—must bring about, that is to say, what has been seen to happen in the first of the two experiments under consideration; namely, preservation of sensation with loss of motion on the side of the lesion, and preservation of motion with loss of sensation on the opposite side. Again, with the sensory and motor conductors arranged in this manner, it is plain that a longitudinal section of the grey substance of the cord midway between the two lateral halves—a lesion indicated in the diagram by the line c A d—must leave the motor conductors a b and a' b' untouched, and cut across the sensory conductors c d and c' d' at their point of decussation—must bring about what happens in the second of these two experiments, viz. numbness on both sides of the body, and paralysis on neither side.

In saying that paralysis without loss of sensation, on the same side of the body, and loss of sensation without paralysis, on the other side of the body, is produced by cutting across a lateral half of the spinal cord, all is not said that has to be said. In such a case there is, in
addition, increased temperature and sensibility on the side on which sensation is preserved, and diminished temperature on the side on which sensation is lost, especially if the section be made high up near the medulla oblongata. It would seem, in fact, that the injury has acted upon the vaso-motor nerves contained in the cord as well as upon the common motor and sensory nerves, causing paralysis of vaso-motor nerves on the side on which there is increased temperature and sensibility, and irritation of vaso-motor nerves on the side on which there is diminished temperature and anaesthesia. At any rate this mode of explanation is neither impossible nor improbable. The experiments of Professor Claude Bernard, Dr. Brown-Séquard, and others upon the cervical sympathetic, prove that when this nerve is paralysed by dividing it, a state of hyperæmia, of which the most conspicuous signs are a bloodshot state of the conjunctiva and of the lining membrane of the nostril and ear, with a contracted pupil, and with increased temperature, is at once set up on the same side of the head: and also that when the end of the divided nerve which is separated from the cord is irritated, the immediate result is dilatation of the pupil, with an almost complete blanching and cooling of the parts which were bloodshot and warm a moment before. The vessels in these parts evidently relax and receive more blood when their nerves are paralysed, and contract and receive less blood where their nerves are irritated; and the increased temperature and sensibility which happens in the one case, and the diminished temperature and sensibility which happens in the other case, are nothing more than the natural consequences of the increased or diminished quantity of blood in the parts in each case respectively. All this is plain enough. Moreover, there are other facts which go to show that phenomena in every way analogous to those which result from paralysis or irritation of the cervical sympathetic are produced by paralysing or irritating vaso-motor nerves in other parts. There is, therefore, no reason why it may not be inferred that the increased temperature and sensibility of one side of the body, and the diminished temperature of the other side, which happen when a lateral half of the spinal cord is cut across, are the result of vaso-motor nerves being paralysed in the one case and irritated in the other case. Nay, such an assumption is well-nigh inevitable, for the structural connexion between the spinal and sympathetic systems of nerves is such as to make it scarcely possible to believe that a lateral half of the cord can be cut across without paralysing and irritating vaso-motor nerves.

Above and below the decussation of the anterior pyramids of the medulla oblongata the conductors which have to do with sensation and voluntary motion are arranged differently in the spinal cord. Above this point, the sensorial and volitional conductors belonging to one side of the body lie together in the same lateral half of the cord, and this half is that which appears to belong, not to the same side of the body, but to the opposite side: at this point, the volitional conductors separate from the sensorial and pursue a different
course to what is the common destination of both conductors alike, the volitional conductors crossing over at once and in a body to the other side of the cord and passing down this side until each one reaches the particular anterior root at which it emerges, the sensorial conductors passing down the same side of the cord and not crossing over to the other side (where they rejoin the volitional conductors) until they arrive at the level of the particular posterior roots with which they are connected. In other words, the sensorial and volitional conductors of the two sides of the body decussate, both of them, in the spinal cord, but not in the same place, the decussation of the volitional conductors being confined to the narrow path where the anterior pyramids of the medulla oblongata intercross, the decussation of the sensorial conductors being all along the spinal cord from one end to the other. Higher up or lower down than the narrow path which has been indicated, there appears to be no intercrossing whatever of volitional conductors.

All the forms of sensorial conductors—those which take cognizance of touch, pain, tickling, temperature, and the rest—appear to follow the same course in the cord, those of the two sides decussating along the whole length of the cord at the level of their entrance or whereabouts, and ascending to the sensorium in the opposite half of the cord to that into which they first pass from the posterior roots; but all the forms of motor conductors do not follow the course of the volitional conductors. Below the point where the anterior pyramids of the medulla oblongata decussate all forms of motor conductors alike seem to agree in not decussating: at this point, the only motor conductors which decussate would seem to be the volitional. Thus, the increased temperature and sensibility resulting from paralysis of vaso-motor nerves, which is produced by cutting into one side of the medulla oblongata, above the decussation of the anterior pyramids, and the persistent spasm which follows irritation of the corpus olivare and the neighbouring parts—which spasm points to the presence there of motor conductors whose function is not yet clearly determined—are on the same side of the body, and not on the opposite side, as they would be if these two kinds of motor conductors decussated like the volitional conductors.

When the continuity of the cord as a conductor is entirely interrupted by being cut, torn, compressed, or injured in any other way, voluntary movement and sensation are immediately abolished in the parts behind the injury, and at the same time the paralysed muscles, especially in the lower extremities, become much more susceptible to reflex action. The increased susceptibility to reflex action is developed immediately, or all but immediately, and it may continue with little change for days, weeks, or even months—a fact which does not appear to be very intelligible on the current view of muscular action, but a fact nevertheless. The higher the seat of injury to the cord, the higher must be the level to which the paralysis reaches, and (if the respiratory muscles be affected at all) the greater the inter-
ference with the breathing, and, as may be easily understood, it is not
difficult to form a tolerably correct diagnosis of the locality of the
injury by taking these variations into consideration. If the injury be
at the upper limit of the sacral region of the cord, the muscles of the
bladder and anus will be paralysed, and so will the muscles of the
lower extremities, with the exception of those which are supplied by
the anterior crural and obturator nerves (the psoas, iliacus, sartorius,
pectineus, adductor longus, a. magnus, a. brevis, obturator externus,
vastus externus, v. internus, rectus femoris, &c.), which nerves come
off from the second, third, and fourth lumbar pairs of spinal
nerves. If the injury be very low down in the sacral canal, the com-
pressor urethrae and the accelerator urinae, as well as the sphincter
ani, will be paralysed, but not the muscles of the legs; for the nerves
of the three muscles, specified by name, come off almost from the
extreme end of the cord, and below those which go to form the great
sciatic. When the injury to the cord is higher up in the cord, in
addition to the loss of voluntary power in the lower extremities and
in the bladder and anus, the respiratory muscles will be more or less
paralysed. If the injury be at the upper limit of the lumbar region,
the lateral muscular walls of the abdomen will be paralysed, and so
will all the muscles of the lower extremities, and one effect of the
paralysis of the abdominal walls will be to compromise greatly the
expiratory movements of respiration. If the injury be high enough
to paralyse intercostal muscles, inspiration will be interfered with as
well as expiration, and the degree of interference will be in propor-
tion to the number of intercostal muscles implicated. If the injury
be low down in the cervical region, all the intercostals will be para-
lysed, and so will the muscles of the upper extremities, except those
of the shoulders, which receive their nerves from higher portions of
the cervical region. If the injury be at or above the middle of the
cervical region—at or above the level of the fourth cervical pair of
spinal nerves—death will at once result from the suspension of all
inspiratory movements. In this latter case it is customary to ascribe
the stoppage of breathing to paralysis of the nerve which supplies the
diaphragm—that is, the phrenic; but this explanation does not go far
enough. The injury which paralyses the diaphragm paralyses the
scaleni, the inter-costales, and the serrati magni, which muscles elevate
the ribs in ordinary respiration, and in so doing play a part which
is scarcely less important than that played by the diaphragm; and
not only so, but it paralyses also the greater number of those accessory
respiratory muscles which, acting upon and from the shoulders,
come to the rescue when a great effort at inspiration is necessary,
and produce additional expansion in the upper part of the chest. Not
only is there a great difference between calm respiration and forced
respiration, but there is a great difference also between the respiration
of males and that of females. "In males," says Dr. Hutchinson, "the
abdomen first bulges outwards, and the ribs and sternum nearest to
the abdomen quickly follow this movement, until the motion, like a
DISEASES OF THE SPINAL CORD.

wave, is lost over the thoracic region. In females, the breathing commences with a gentle heaving of the upper part of the thorax, more or less apparent according to the fulness of the mammae, and with some slight elevation of the shoulders; and this movement of expansion spreads from rib to rib in a downward direction, and any bulging of the abdomen from the descent of the diaphragm is distinctly after this heaving of the lateral walls of the chest, not before it." In females also this bulging of the abdomen is so inconsiderable that the number of respirations cannot be counted by the hand resting on that region as it can be in the male. In calm breathing, in fact, the diaphragm does more and the ribs do less in males than in females, and this difference is so real that, for the sake of distinction, calm breathing may be spoken of as diaphragmatic in males, and as costal in females. This difference, indeed, is such that respiratory movements which are healthy in women are morbid in men; and vice versa, that movements which are healthy in men are morbid in women. "In forced breathing," Dr. Hutchinson again says, "the greatest enlargement of the thoracic cavity in both sexes is made by the ribs and not by the diaphragm, as is generally believed;" and that this statement expresses what really happens, appears to be evident in the fact that in such breathing the hollow at the pit of the stomach, instead of being filled out and protruded, as it must be if the diaphragm descended in any marked degree, is actually drawn in and depressed. In forced breathing, indeed, the costal inspiration of women becomes more costal, and the diaphragmatic inspiration of men changes from this form to the costal. It is certain, however, that there may be forced diaphragmatic breathing as well as forced costal breathing, and that the one may be made to take the place of the other by an easy effort of the will, or by changes of position which interfere with the action of the diaphragm on the one hand, or of the ribs on the other. There is, indeed, no difficulty in understanding why diseases which interfere with the action of the diaphragm or ribs should make the breathing costal or diaphragmatic, as the case may be. As regards the expiratory movements of respiration there is little to say. In tranquil breathing, in males and in females alike, expiration is performed by the relaxation of the diaphragm allowing the abdominal viscera to press up into the position from which they had been depressed in inspiration by the contraction of this muscle, by the relaxation of the costal muscles allowing the ribs to spring back into the position from which they had been pulled up in inspiration by the contraction of these muscles, and by the resiliency of the air-passages themselves. In forced expiration the lateral and inferior muscular walls of the abdomen will help to empty the chest by pulling down the ribs and by contracting upon the abdominal viscera, so as to cause them to push up the diaphragm more effectually. It is easy, indeed, to see how a lesion of the spinal cord which paralyses the lateral and inferior abdominal walls must interfere with the movements of expiration, and especially with such violent movements as coughing or sneezing. In a word,
the whole case of the respiratory movements is one which makes it impossible to continue in the belief, that the one reason why the division of the cord at or above the origin of the phrenic nerve proves fatal, is because the diaphragm is paralysed; for the plain fact is, that the injury which paralyses the diaphragm paralyses the muscles which elevate the ribs, both ordinary and extraordinary, and so puts an end to movements which are quite as important as those of the diaphragm, if not more so, in carrying on respiration. Of the other phenomena which may be present when the injury which interrupts the continuity of the cord as a conductor is in the neck, but not so high as to destroy life immediately, and which are not likely to be present when the injury is much below the cervical region, difficulty of swallowing, difficulty in vocalization, contraction of pupils, palpitation, and priapism appear to be the most important.

In these remarks the name of Dr. Brown-Séquard has been mentioned more than once, and it might have been mentioned oftener very easily. Indeed, it is not too much to say that the discoveries of this very distinguished physiologist mark a new epoch in the physiology and pathology of the spinal cord.

2. On the practical significance of pain and spasm, and of certain other symptoms more or less akin to pain and spasm.—Have these symptoms to do with inflammation, or with a state which, though not unfrequently passing into inflammation, is in reality diametrically opposed to inflammation? This is the question to which I propose now to seek the answer, first, in relation to pain and the symptoms akin to pain, and, secondly, in relation to spasm and the symptoms akin to spasm.

(a) On the practical significance of pain and the symptoms akin to pain.—There are some points in the history of common neuralgia—the beginning and ending of the paroxysm periodically at a given time, the association of the pain with rigors, the frequent ending of the pain in an obscure fit of feverishness, and others—which are calculated to suggest some relationship between this disorder and ague. It would seem, indeed, especially in that form of neuralgia which is met with in agueish districts, as if the neuralgia and the rigors were companion symptoms—as if there was some connexion between the pain and a depressed state of the circulation such as is met with in the cold stage of ague. There is also some reason to believe that neuralgia is antagonised rather than favoured by inflammation and fever. It is no uncommon thing for the history of facial neuralgia or tic-douloureux to be this:—first, neuralgia, without local tenderness and swelling, and redness, and with frequent chills and shivers, and a decidedly depressed state of the circulation; afterwards, cessation of neuralgia, cessation of chills and shivers, with local tenderness, redness, and swelling, and with some slight feverish reaction. What I have experienced in my own person, as well as what I have witnessed in others, enables me to speak with all confi-
DISEASES OF THE SPINAL CORD.

dence upon this point. It is also the rule, rather than the exception, for the neuralgic pain of toothache to come to an end when the face becomes swollen and inflamed; and it does not seem to be otherwise with the stabbing neuralgic pains which so generally precede the inflammatory eruption of herpes, for it is usual for these pains to subside concurrently with the development of the eruption. Nay, I know of several cases of sciatica, in which the relief to the neuralgic pain was coincident with the development of a tenderness which seemed to betoken neuritis at one or more points in the course of the painful nerve and in which, after this change, the patient was comparatively free from pain so long as the lame limb was kept still and let alone. With respect to neuralgia, in all its manifold forms, indeed one thing is certain, and this is, not only that neuritis is not necessary to its production, but also that this form of inflammation is at most a very exceptional complication.

Nor is a different conclusion to be drawn from the history of rheumatic and gouty pain.

In acute rheumatism it is generally found that the pains which had been torturing the patient for days, or weeks, or months previously, preventing him from being at ease in the daytime, and causing him to toss about in sleepless misery at night, come to an end when the feverish reaction and local inflammation of the fully-formed disorder make their appearance. After this, the joints are tender enough; but if the patient keep as still as he is very likely to do under the circumstances, he is comparatively or actually at ease so far as his old rheumatic pains are concerned. Or, if it be otherwise, the pains will generally be found to be in a part in which the signs of rheumatic inflammation are imperfectly established or absent, or else at a time when there is a decided remission in the feverish reaction—an event which happens more frequently in this disorder than is commonly supposed.

And certainly it is simply impossible to look upon the local inflammation of gout as essential to the racking pain of this disorder. "About two o'clock in the morning," says Sydenham, who knew full well from personal experience what he ought to say, "the patient is awakened by a severe pain in the great toe, or, more rarely, in the heel, ankle, or instep. The pain is like that of dislocation, and yet the parts feel as if cold water were being poured over them. Then follow chills and shiverings, and a little fever. The pain, which was at first moderate, becomes more intense; and with its intensity the chills and shiverings increase." After tossing about in agony for four or five hours, often till near daybreak, the patient suddenly finds relief, and falls asleep. Before falling asleep, the only visible change in the tortured part is some swelling in the veins; on waking in the morning the part has become swollen, shining, red, tender beyond measure, and more or less painful, but painful only to a degree which is as nothing in comparison with the torture of the night past. It seems, indeed, as if the pain which
now exists may in great measure be referred to the mere tension and stretching of the inflamed ligaments, for it may be relieved, or even removed, by judiciously applying support to the toe and sole of the foot. On the night following, and not unfrequently for the next three or four nights, the sharp pain may return, reappearing and disappearing suddenly, or almost suddenly, and resulting in the development of additional inflammatory swelling in the interval between falling asleep and waking in the morning. The pain in these relapses, like the pain in the first attack, is accompanied by chills and shivers, and by the most distressing irritability and excitability; but, until unequivocal signs of inflammation are developed in it, the painful part is not tender in the true sense of the word. The inflammation, moreover, is attended by no fever, or by very little; or if it be otherwise, as it is occasionally, the inflammation runs higher than usual, and the characteristic pain is less urgent than usual. Dr. Garrod points out this latter fact in his excellent work on gout. From its history, then, it would seem as if the pain went hand in hand with the rigors which belong to the cold stage of gouty inflammation. It would seem as if the inflammation, as inflammation, had little to do with the pain; for if it were otherwise it is scarcely to be supposed that the pain should be least urgent in the cases of gout in which the inflammation is most marked, and that the unequivocal signs of inflammation should make their appearance during sleep without waking the patient. Nay, it would even seem as if the pain were put an end to by the establishment of inflammation—as if, in fact, the pains were antagonised rather than favoured by the inflammatory condition. Moreover, the suddenness with which it begins and ends in the majority of cases must be looked upon as a reason for referring the pain to the category of neuralgia—a disorder with which, as I have already shown, inflammation has no necessary connexion.

There is also reason to believe that pain holds the same relation to fever and inflammation in other kinds of fever besides the rheumatic, and in other kinds of inflammation besides the gouty.

The pain in the back, often very severe, which ushers in small-pox, disappears before the hot stage is fully established. It comes and goes hand in hand with the rigors, and it belongs to the cold stage as evidently as do the rigors. And this would seem to be the case also in other fevers; for it is the rule, and not the exception, for the pains which attend upon the onset of these disorders to pass away or to become greatly mitigated as soon as the cold stage gives place to the hot. Nay, it would seem as if pain gave place for the time to what may be called artificial feverishness. At any rate, I have more than once felt tic-douloureux in my face pass away as soon as I could set my blood in brisk motion by violent bodily exercise; and on two occasions I have put a stop to a sudden attack of lumbago while in the saddle, by a practice which is not unfrequently adopted in such a case in the hunting-field,—that is, by leaning forwards, and beating the loins
with the hands until the whole body was aglow, and the perspiration dropped from the forehead.

The acute pain of a dislocation or sprain—the pain to which Sydenham likens that of gout—does not, as a rule, remain after the parts have begun to be hot and tender and swollen; and as a rule, also, the pain of idiopathic inflammation goes before, and not along with, the redness and heat and swelling. In the idiopathic, as well as in the traumatic forms of inflammation, it would seem, indeed, as if the pain were related to the cold stage of the disorder, and not to the hot. Nor is a contrary conclusion to be drawn from the history of those cases in which the pain continues after the hot stage of the inflammation is fully established, for in these cases this persistent pain is evidently (in great measure at least) due to the stretching of parts made tender by the inflammation. Thus, for example, the pain which remains after the hot stage is fully established in orchitis and pleuritis, is at once removed or relieved by means which obviate this stretching—in the former case by the free use of the knife, in the latter case by the application of a roller around the chest so as to prevent the movement of the ribs over the seat of inflammation.

Even in inflammation of the membranes of the brain, severe pain in the head cannot be looked upon as a symptom of this inflammation. Three or four years ago I had a youth in the Westminster Hospital with well-marked symptoms of acute cerebral meningitis. When I first saw him, he complained of frequent rigors and of a constant agonizing pain in the head, and at this time his face was pale and perspiring, his ears and his head generally were below the natural temperature, his pupils somewhat dilated, and his pulse contracted and feeble. Eight hours afterwards, when I saw him the second time, his face was flushed, his head burning hot, his pupils contracted, his eyes ferrety, his skin hot and dry, his pulse strong and full, and fierce delirium had taken the place of the pain. And this, so far as my experience goes, is the regular history of pain in this disorder. It is pain ceasing, not pain beginning, as the symptoms of active determination of blood to the brain make their appearance. It is pain in association with an anemic rather than with a hyperemic condition.

For these among many reasons it is that pain (with the exception of that form of pain which is dependent on tenderness, and which is accidental only) does not appear to be a symptom of inflammation or fever. In inflammation or fever the pain would seem to be connected with the cold stage preceding the hot stage, and not with the hot stage itself—with a state of capillary contraction and deficiency of blood, and not with a state of capillary relaxation and excess of blood—with a state of vaso-motor irritation, and not with a state of vaso-motor paralysis: in other cases, the pain would seem to have to do with a state of circulation which is in reality closely akin to that which exists in the cold stage of inflammation and fever. Pain, however, must not be regarded as a symptom of inflammation or fever because it happens to be associated with the so-called cold stage of
A SYSTEM OF MEDICINE.

these disorders. In point of fact, this so-called cold stage of inflammation or fever is a state which is diametrically opposed to the so-called hot stage. In this cold stage, the vaso-motor nerves (and not these nerves only) are in a state of irritation, and, as the result of this irritation, the capillaries are contracted and bloodless; in the hot stage, on the contrary, the vaso-motor nerves are paralysed, and, as the result of this paralysis, the capillaries are relaxed and bloodshot. Instead of being stages in the same process, the so-called cold stage and the so-called hot stage are conditions diametrically opposed to each other. Instead of being stages in the same process, it would rather seem that the hot stage has a remedial relation to the cold stage—that, within certain limits, the hot stage is the salutary refluence of a tide of life which has ebbed too low in the cold stage. It is not difficult to see that there is an intimate connexion between the so-called cold stage and the so-called hot stage, and that the first may easily change into the second. It is not difficult to see that there must be this relation between these stages; for if, as there is good reason to believe, irritation of vaso-motor nerves may bring about the cold stage by causing contraction of vessels, it is easy to understand that the paralysis of vaso-motor nerves, which follows when this irritation is carried beyond a certain point, may lead to the hot stage by causing relaxation of vessels. At any rate, be this as it may, the plain fact would seem to be that pain, with the exception of that form of pain which is dependent on tenderness, is a symptom belonging to the so-called cold stage of inflammation and fever, or to a state of circulation closely akin to it, and not to the hot stage of inflammation and fever, or to a state of circulation akin to it. Nay, it may even be supposed, and not without some show of reason, that pain must be associated with contracted and empty capillaries; for, the sympathies of the nervous system being what they are, it is not easy to believe that the vaso-motor nerves do not participate in the irritation which acts on the sensory nerves, and which, so acting, gives rise to pain.

And if this be so—and this is the practical conclusion to which these remarks tend—it follows that pain is likely to be relieved by measures which are calculated to rouse the circulation and increase the quantity of blood in the capillaries of the principal part, and not by those which have a contrary action.

With regard to tingling and other symptoms which are more or less akin to pain there is little to say. Indeed, all I can say is that the history of these symptoms, so far as it is known to me, would seem to agree rather than to disagree with that of pain, in connecting them with a state of irritation, and not with a state of actual inflammation.

(b) Of the significance of spasm and the symptoms akin to spasm. The violent and general epileptic form of convulsion which attends upon death by hæmorrhage or suffocation is associated with a defective and not with an excessive supply of arterial blood to one or other of the great nerve-centres. Nor is it otherwise with ordinary epileptic or epileptiform convulsion. The deathly paleness of the
countenance which precedes the convulsion is, indeed, a plain proof that the fit commences in a state of circulation which is the very opposite to that of active determination of blood to the head, and the strong pulse which is usually perceptible in the arteries as the fit progresses is no contradiction to this conclusion. This strong pulse is usually regarded as a sign of arterial excitement—as a proof that more arterial blood is being injected into the arteries at this time, and that, on this account, certain nervous centres are excited to an unwonted degree of activity: but the simple fact is, that the strong pulse which is present under these circumstances derives its strength, not from arterial blood, but from venous. Black blood is being pumped into the arteries at the time, and because black blood moves less readily through the capillaries than red blood, the arteries become distended and the pulse endowed with a counterfeit power. The strong pulse in question is caused by the suffocation which is a part of the fit: it is a pulse of black blood and not of red, as may easily be proved by making an opening into the artery: it is nothing more, in fact, than the natural pulse of suffocation. Hence, the strong pulse of the epileptic or epileptiform paroxysm is no proof that this form of convulsion is connected with an excited condition of the circulation: on the contrary, when rightly read, it points only to the opposite conclusion.

It would seem also that convulsion is not associated with an over-active condition of the circulation, even in those cases in which at first sight it might appear to be so. In the fevers of infancy and early childhood, especially in the exanthematous forms of these disorders, convulsion not unfrequently takes the place occupied by rigor in the fevers of youth and riper years. It occurs in the initial cold stage, or else in the last moments of life, not in the intermediate hot stage. Again in inflammation of the membranes of the brain, convulsion, when it occurs, is connected with the cold stage before the hot stage, or with the cold stage after the hot stage, and never with the hot stage itself. Nay, I am disposed to think that there is something altogether un congenial between convulsion and a state of febrile reaction in the circulation, for it is a fact not unfrequently verified that fits of common epilepsy are often suspended during the continuance of such reaction.

As indeed I have endeavoured to show at length elsewhere, especially in the lectures which I delivered at the Royal College of Physicians, in London, in 1862 (post 8vo. London: Churchill and Sons), the physiology and pathology of muscular action, so far as I can read them, serve only to connect all the varied forms of tremor, convulsion, and spasm, with diminished and not with increased activity of the circulation; and thus the practical significance of spasm and the symptoms akin to spasm would appear to be the same as that of pain and the symptoms akin to pain—namely this, that the measures calculated to afford relief are likely to be those which will rouse the circulation to greater activity and increase the quantity of blood in the capillaries, and not those which have a contrary action.
B. ON DISEASES OF THE SPINAL CORD.

Under the head of diseases of the spinal cord there is no lack of subjects. As of primary importance may be mentioned spinal meningitis, myelitis, spinal congestion, tetanus, and spinal irritation; as of secondary importance, locomotor ataxy, reflex paraplegia, infantile paralysis, hysterical paralysis, &c. I shall take each of these subjects in the order in which it has been enumerated, and, as far as I can, apportion the limited space at my command (very limited for such a purpose) so that there may be room for saying most where most is wanted.

I. MENINGITIS.

Inflammation of the membranes of the spinal cord is usually associated with inflammation of the substance of the cord (myelitis) or with inflammation of the membranes of the brain, but uncomplicated cases do occur now and then, and with care it is not difficult to discriminate between the symptoms which are essential to spinal meningitis and those which are only accidental.

1. SYMPTOMS.—In order to arrive at a knowledge of the symptoms of spinal meningitis, I will relate as a text one of three cases verified by post-mortem examination which have come under my own notice, and then proceed to see wherein it agrees with or differs from other cases of the kind. I choose an acute case rather than a chronic one, for it is only in the acute form of the disease that the symptoms are to be defined with certainty.

Case.—A lightly-made, delicate-looking youth, nineteen years of age, a cigar-maker by trade, was admitted into one of my wards in the Westminster Hospital on the 27th December, 1864.

(a) When I saw him first—this was on the day after his admission—he complained chiefly of pain in the back and great general weakness and weariness, and expressed his belief that he had got rheumatic fever. He was then sitting by the fireside, and looking very ill. On telling him that he had better lie down, he got up and walked towards his bed, or rather he attempted to do so, for the first step brought on a severe pain in the back and legs, with a feeling of faintness and want of breath, and he would have fallen if assistance had not been at hand. Very soon after lying down he passed about a quart of water without any difficulty.

(b) The account he gives of himself is this. A week ago, after being very tired by a long walk, he was seized by shiverings and sharp pain between the shoulders. During the next three days he was feverish and without appetite, but still able to go about and do his work. All this while, he had very little pain, and his nights were not
DISEASES OF THE SPINAL CORD.

595

disturbed. On the night of the fourth day from the commencement of the illness he was awakened by violent pain along the whole course of the spine, in the groins, and in the right leg. Next day the pain occurred several times in paroxysms, and was accompanied by a good deal of starting and jerking in the legs; and so also on the two days following. On the day before admission to the hospital some difficulty in opening the jaw was experienced, and the paroxysms of pain, and jerking, and starting, had become more frequent and urgent. All this while the bowels and bladder acted properly.

Dec. 28.—There is no material change since yesterday—not for the worse, certainly.

Dec. 29.—Last night, after three or four hours' sleep, the patient awoke with very severe pain along the spine and down both legs; and since that time the pain has recurred several times. These attacks are separated by intervals of comparative or complete ease, and instead of the jerks and starts, which went hand in hand with it previously, the pain is now accompanied by stiffness in the muscles of the back and legs. At the present moment (about 2 p.m.) the head is drawn back on the pillow, and considerable pain and stiffness in the neck is caused by moving it. Before making this movement the patient was free from pain and stiffness in this region. Asking him to try to sit up, he attempted to do so, but was stopped at once by a severe paroxysm of pain along the whole length of the spine and down the legs, and by the muscles in the painful parts becoming stiff. The action of the muscles produced in this way arched the body backwards almost as much as in ordinary cases of tetanus, and at the same time pursed up the mouth and eyes, and gave a set expression to the features generally, so that the patient for the time had the appearance of a person considerably older than himself. The pain went off in a few minutes, and soon afterwards the stiffened muscles relaxed. The effort to move one of the legs spontaneously gave rise to sharp pain in the thigh and loins, and the limb became somewhat stiffened in a semi-flexed position, and this state of things did not pass off for several minutes: and passive movement produced the same result. There was no numbness: on the contrary, the condition of the skin as to sensation everywhere, as judged by pricking and pinching and by differences of temperature, was plainly that of slight oversensitiveness. Pressure along the spinal column failed to detect tenderness anywhere, and the result of applying a sponge wrung out of hot water was equally negative.

In the course of the examination it was evident that any movement of the body, or neck, or legs, active or passive, gave rise to pain and stiffness in the muscles moved; and also that there was little or no pain or stiffness so long as the patient kept quite still. It was evident, in fact, that the muscles were relaxed, except perhaps in the neck, in the intervals between the paroxysms. The poor sufferer was evidently in a great strait, dreading all movement, because he knew full well what the effect of movement would be, and at the same time con-
tinually prompted by an intolerable feeling of unrest and fidgetiness to wish to have his position changed in a way which he could not or dared not compass by his own efforts: and it is difficult to avoid the conclusion that the stiffness is, in the main, an instinctive act to prevent the movement which gives rise to the pain, rather than spasm like that which is met with in tetanus. The arms are affected as well as the legs, but not to the same degree. They are weak—so weak that it is not easy to find strength to carry the food to the mouth, the left arm being somewhat the weaker of the two. The left arm also cannot be moved, either actively or passively, without giving rise to pain and rigidity, to pain shooting up between the shoulders, to rigidity flexing the limb somewhat at the elbow, and bending the thumb slightly into the palm: not so the right arm. There is no numbness in either arm, and no very decided over-sensitiveness. Mastication is difficult, and deglutition still more so, apparently from the muscles set in movement becoming stiff in moving. The breathing is shallow and slow; the pulse quick (130) and very wanting in strength; the skin profusely perspiring after a paroxysm, and hot and moist at other times. Thirst is much complained of. The bladder is full, and it cannot now be emptied voluntarily. The urine is acid. The penis is flaccid, and has been so ever since the commencement of the illness. The bowels have not acted. The pupils are equal and natural, and there is no headache or other "head symptom."

Dec. 30.—A tolerably good night has been passed, and this afternoon the patient thinks himself a little better.

Dec. 31.—There has been a bad night, and much ground has evidently been lost since the last visit. In a paroxysm which is just over, want of breath was experienced rather than pain. Sensation is still somewhat exaggerated everywhere. Urine cannot be passed without the catheter, but the bowels have responded to-day to a dose of castor-oil and spirits of turpentine which was administered yesterday. During my visit I had an opportunity of seeing the patient after a paroxysm as well as in it, and I quite satisfied myself that the muscular stiffness of the paroxysm soon passed off, and that in the interval between the paroxysms the muscles were relaxed, except perhaps at the back of the neck—with this possible exception, because all along the head remained drawn back to some degree upon the pillow.

Jan. 1, 1865.—The night has been perfectly sleepless, with now and then some trifling lightheadedness. The paroxysms of pain, stiffness, and difficulty of breathing are not so frequent (three hours have passed since the last), but the respiration is certainly shallower and less sufficient, and the pulse more rapid and unsteady. There is the same want of power over the bladder. When I left the ward it was plain enough that the patient was sinking: when I returned two hours later all was over, death having happened in a fit of choking and suffocation caused by attempting to swallow a spoonful of beef-tea with a morsel of bread sopped in it. In the agony, the
patient not only sat up in bed, but got out of bed and stood for a moment with his hands bearing upon the shoulders of the nurse who had been feeding him. The body was examined after death by my friend and colleague, Dr. Bazire, and the following notes were taken at the time from his dictation:

"Time, twenty-four hours after death. Weather frosty. Cadaveric rigidity well marked. The muscles of the back dark and highly congested. On cutting through the posterior arches of the vertebrae the vertebral vessels are seen to be gorged with dark fluid blood. There is no effusion of blood outside the meninges in the interior of the canal. The meninges are highly congested throughout the whole length of the canal, but to a considerably greater degree in the region between the scapulae. In this latter region, in addition to the thickening, opacity, and intense red colour of the dura mater elsewhere, there are streaks in its substance of black coagulated blood. The arachnoid is intensely red, and the pia mater extremely congested in the same region. Beyond it, the dark red colour of the dura mater gradually passes into a lighter shade, and becomes a bright pink near the cauda equina in one direction, and near the medulla oblongata in the other. The arachnoid is whitish again near the cauda equina. There is no effusion of serosity, blood, or pus, either between the meninges or on the surface of the cord; indeed, there seems to be a smaller quantity than usual of cerebro-spinal fluid. The substance of the cord itself looks normal in consistence, colour, and size. The central vessel of the cord is highly congested, and on section of the cord there exudes from the centre fluid black blood in minute drops. The cerebral meninges are normal. The cerebral sinuses are highly congested, and the same appearances of congestion (due probably to the mode of death) are met with in the substance of the brain. The organ itself is normal."

The symptoms of acute spinal meningitis are plainly exhibited in this case, and there need be no difficulty in distinguishing those which are of primary importance from those which are secondary.

As symptoms of primary importance may be enumerated these:—
fits of pain along the spine and in the extremities produced by movement; fits of muscular stiffness in the painful parts along with the pain; intervals of comparative or complete freedom from pain and muscular stiffness so long as movement can be avoided; absence of paralysis; some exaltation of sensibility; loss of power over the bladder; partial loss of power over the bowel; absence of spinal tenderness.

Fits of pain along the spine and in the extremities produced by movement.—This pain, as I think, must be regarded as the most prominent symptom in acute spinal meningitis. It may be confined to the region of the spine, but more generally it shoots into the extremities, into the legs especially. As a rule, it does not shoot beltwise round the trunk. It is brought on by any movement of the trunk, and, in great measure at least, it may be prevented by avoiding such movement. It is often
brought on also by moving one of the extremities, the pain in this case beginning in the limb, and extending thence to the spine. It seems to depend, in part at least, upon the same cause as the pain of pleurisy, viz. the dragging of an inflamed and therefore exquisitely tender serous membrane, and its character is certainly more like the pain of pleurisy than of rheumatism (to which it has been likened), for it occurs in the same sharp, sudden, breath-stopping catches.

**Fits of muscular stiffness in the painful parts along with the pain.**

—It is usual to regard this stiffness as analogous to the spasm of tetanus: it is necessary, as I believe, to look upon it as expressing an instinctive act of muscular contraction, of which the object is to prevent pain by arresting certain movements which produce pain. The spine and extremities cannot be moved without causing pain: the stiffness prevents the pain by preventing the movement; this would appear to be the true view. This explanation, originally given by M. Dance as applying to the muscular stiffness in a case of acute spinal meningitis observed by him and recorded by M. Ollivier, applies perfectly to the muscular stiffness of the case which has been related as the text, and it applies, as I believe, with the same exactness to all cases of the kind. Indeed, I believe there can be no greater mistake than to confound the stiffness in question with the spasm of tetanus. This will be seen more particularly when speaking of tetanus: and here I will only say that tetanus in its most violent form is constantly present where there are no signs of spinal meningitis, and that, in the few cases in which such signs chance to be met with, it may be supposed that the inflammation is a consequence rather than a cause of the irritation which gives rise to the tetanic spasm—a consequence of the irritation in the vaso-motor nerves having proceeded until it has issued in paralysis of the vaso-motor nerves. Nay, after what has been said in the preliminary remarks, it is not impossible that the spinal meningitis which is occasionally associated with tetanus may have served to counteract the spasm rather than to cause it. At any rate, it is certain that spasm of the spinal muscles is not so marked a phenomenon in acute spinal meningitis as in tetanus, and that it is not to be regarded "comme indiquant positivement la phlegmasie des membranes de la moelle;" and it is, to say the least, highly probable that the muscular stiffness which simulates true tetanic spasm is in great measure an instinctive act of muscular contraction to prevent a movement which produces pain.

**Intervals of complete or comparative freedom from pain and muscular stiffness so long as movement can be avoided.**—These intervals are sometimes of considerable length, even for days. According to my own experience, indeed, the rule would seem to be that as long as the patient can keep still, so long is he, comparatively at least, free from pain and stiffness—a rule which is very different from that which obtains in tetanus.

**Absence of paralysis.**—The patient is weak, very weak, and he seems to be paralysed, but in reality he fears to move because move-
DISEASES OF THE SPINAL CORD. 599

ment brings back the pain. “Les mouvements, qui sont en quelque sorte enchaînés par la douleur, ont moins de force, mais ils ne sont point paralysés.” (Ollivier, p. 595.) Let this fear be forgotten, and it is possible not only to sit up, but to get out of bed and stand, as happened in the final agony of the patient whose case I have given. This power of movement has been noticed in several cases, of which one is related by Ollivier, and another referred to; and I believe it would be witnessed in all cases of uncomplicated acute spinal meningitis in which the fear of suffering pain from movement was not the one absorbing feeling.

Some exaltation of sensibility.—In the case which I have given there was some exaltation of sensibility as to touch, pain, and differences of temperature, but to no very marked degree; and this would appear to be the rule in cases of the kind. It would seem, indeed, that numbness is a purely accidental symptom, which is never present unless the substance of the cord is implicated in the meningeal inflammation.

Loss of power over the bladder.—In acute spinal meningitis, when the symptoms are fully developed, this particular symptom is scarcely ever absent, if ever. Before this time it may be absent, as it was in the case on which I am commenting; but this absence must certainly be looked upon as the exception rather than the rule. Not frequently the inability to empty the bladder is preceded by a state of irritability which makes it necessary to pass water almost incessantly.

Partial loss of power over the bowel.—On this point M. Ollivier makes a remark which is certainly true: “Je ferai remarquer que l’abolition des fonctions de la vessie persiste toujours au même degré depuis le commencement jusqu’à la fin, tandis qu’il n’en est pas de même pour l’intestin, puisqu’il y a assez souvent des garderobes naturelles dans les derniers temps de la maladie.” (Vol. ii. p. 601.)

Absence of spinal tenderness.—This absence is certainly a common, if not a constant, feature of acute spinal meningitis. In some chronic cases, no doubt, there may be some local spinal tenderness, but on inquiry these prove to be cases in which the phenomena of spinal irritation are mixed up with those of spinal inflammation—in which the inflammatory affection is complicated with that condition of which, as will appear in due time, local spinal tenderness is the distinctive feature.

These are the points which may be regarded as of primary importance in comparison with those which have still to be considered, namely—absence of marked spasmodic symptoms, difficulty of mastication and deglutition, difficulty of breathing, no increased reflex excitability, no priapism, fits of perspiration, no active inflammatory fever, no marked “head-symptoms.”

Absence of marked spasmodic symptoms.—The rigidity which attends upon the paroxysms of pain has been seen to be in the main an instinctive act of muscular contraction to prevent a movement which produces pain, and there appear to be no other symptoms of a spasmodic character which occupy a conspicuous place in the history.
of spinal meningitis. Or if there be any such symptoms, these are in all probability confined, as were the jerks and starts in the case under consideration, to that early period of the disorder in which it may be supposed that actual meningeal inflammation was not developed— to the so-called cold stage of the disorder probably.

**Difficulty of mastication and deglutition.**—This difficulty is often absent, and when present it is at most a trifling trouble comparatively. There is no true trismus as in tetanus; there is at most only stiffness which prevents the jaws from opening easily and moving freely. This stiffness, moreover, is late in making its appearance, whereas in tetanus trismus is one of the very first symptoms. In a word, difficulty of mastication and swallowing would seem to occur only in those cases of spinal meningitis in which the higher portions of the cord are implicated.

**Difficulty of breathing.**—This difficulty is always present in some degree, and especially during a paroxysm of pain and stiffness. In some cases, indeed, the movement of the chest may be actually suspended at this latter time, and death may happen from this cause, as indeed was the case in a patient whom I saw not long ago with Dr. Julius of Richmond.

**No increased reflex excitability.**—This is not, perhaps, what might be expected theoretically: but, be the explanation what it may, the fact would seem to be that reflex irritability is not increased in acute spinal meningitis in the way in which it is ordinarily increased in tetanus. So far as I have been able to ascertain there would seem to be no material change in reflex excitability in the meningeal inflammation.

**No priapism.**—The cases in which erection of the penis would seem to be a symptom appear to be those in which the substance of the cord is affected rather than the membrane—cases too in which the seat of the disease is in the cervical and upper dorsal region rather than in the lumbar region. At any rate, it would seem to be the rule for the penis to be flaccid in uncomplicated cases of acute spinal meningitis.

**fits of perspiration.**—As in tetanus these follow a paroxysm almost invariably, especially in the latter stages of its disease. Of this there appears to be sufficient evidence.

**No active inflammatory fever.**—Thirst is a frequent symptom throughout, and there may be at first some heat of skin, but in the most acute cases there is little or no active sympathetic fever. On the contrary, there is usually, even in the cases which have most claim to be considered as acute, a decided want of febrile reaction from the beginning to the end.

**No marked head-symptoms.**—In very many cases inflammation of the spinal meninges is only a part of a more general disorder in which the cerebral meninges are also implicated, and, therefore, "head-symptoms" of one kind or other will often enough be mixed up with the spinal symptoms; but in cases like the one under con-
DISEASES OF THE SPINAL CORD.

consideration, where the spinal meninges were alone inflamed, "head-symptoms" do not figure at all, or figure only as phenomena of very secondary importance. Upon this point there is no lack of evidence. Where spinal meningitis is chronic in its course its symptoms are often so mixed up with the protean symptoms of spinal irritation (of which more in due time) as only to be detected with great difficulty. It may be suspected that the meninges are affected by inflammation rather than by simple irritation if fits of pain and stiffness are produced by movement in the spine and extremities, and if there be at the same time no spinal tenderness, no paralysis, and no tingling or numbness; and this is all that can be said except this, that this suspicion will gather strength if there be chronic disease in the bones and ligaments of the spine. But it may be questioned whether long-continued contraction of the muscles of one or more of the extremities or of the cervical muscles can be reckoned among these symptoms, for such contraction is certainly common enough in cases where the only condition of disorder in the spinal cord or its membrane is one which, from the sudden way in which it begins and ends, and for other reasons as well, would seem to be one of simple irritation.

2. Post-mortem Appearances.—As Ollivier pointed out, the traces of spinal meningitis after death are met with usually, not in the arachnoid membrane, which is non-vascular, but in the subjacent vascular tissue. The arachnoid is so thin and transparent as to allow the vascular injection produced by the inflammation in the deeper structures to appear through it, and that is all. This injection is generally less evident on the surface of the cord than on that of the dura mater, because in the former place it is hidden by the effusion of turbid, sero-purulent, or purulent fluid in the space between the arachnoid and pia mater—in the space naturally occupied by the rachidian fluid—is hidden by an effusion which, before the arachnoid is opened, often causes the cord to have a swollen, opaque, yellowish-white, or yellowish appearance. Any fluid effusion is usually in this space, but sometimes there may be fluid, in this case often sanguineous, in the space outside the dura mater, especially if there be disease in the bones or ligaments of the spine. Sometimes the rachidian space is obliterated here and there by inflammatory adhesions; sometimes the surface of the arachnoid is roughened or otherwise altered by calcareous or other deposits in patches; sometimes the opposed surfaces of the arachnoid are more or less adherent; but generally the surfaces of the arachnoid are smooth and free, and the inflammatory products are met with below this membrane, and not above it. Very often, also, the proper signs of spinal meningitis are mixed up with those of cerebral meningitis or myelitis, or with those of disease in the bones or ligaments of the spine.

3. Causes.—The causes of spinal meningitis are often very obscure. In some cases it is rheumatism, or syphilis, or the suppression of some
menstrual, haemorrhoidal, or other habitual discharge, or the spreading of cerebral meningitis downwards, or of disease in the bones and ligaments of the spine inwards, which would seem to figure as a cause; in other cases it is a casual injury to the back, or a chill caught by lying on the back on the cold and damp ground, or some particular disease, as tetanus, chorea, or hydrophobia, to which blame appears to belong. In fact, the causes are legion, and it is impossible to connect spinal meningitis with any particular cause or set of causes.

4. Diagnosis.—One or two points of diagnosis have been mentioned incidentally when dealing with the symptoms of spinal meningitis, and with these it is best to be content at present, for before this matter can be gone into advantageously materials must be had which can only be forthcoming when the phenomena of myelitis, spinal congestion, and other spinal maladies have been passed in review.

5. Prognosis.—Acute spinal meningitis is, without doubt, a very formidable and fatal disease. There are, indeed, few well-authenticated instances of recovery on record, and by some it is doubted whether there be any. Life may be cut short in four or five days, or it may be prolonged to twenty or thirty days, but not often,—not often, indeed, beyond six or seven days. In the sub-acute and chronic forms of the disease, the prognosis is of course less gloomy, but even here it is far from cheering.

6. Treatment.—In all cases of spinal meningitis, rest in the recumbent position, more or less strictly enforced according to the urgency or leniency of the symptoms, is indispensable, the best position, perhaps, being not strictly on the back, but rather upon the side, and with the limbs a little lower than the back, so as to favour the draining away of blood from the congested parts, and, at the same time, to facilitate the use of the local applications to the spine which may be necessary. Upon this point there can be little or no difference of opinion; upon all other points, in all probability, few will think alike. For my own part, I should be disposed to place most confidence in iodide of potassium and opium, with the local application of ice to the back in acute cases, and to bichloride of mercury, with counter-irritation in one form or other to the spine, in chronic cases. At the same time, I am inclined to think that the present fashion has set very unwarrantably against the old practice of giving calomel and opium, so as to affect the gums slightly and speedily, and of using local, if not general, bleeding in acute inflammatory disease. There can, I think, be little doubt as to the marked influence for good of calomel and opium in acute inflammation of serous membranes; and it would require very little persuasion to induce me to prefer this mode of treatment to that by iodide of potassium in acute spinal menin-
DISEASES OF THE SPINAL CORD.

603

gitis; and, further, I can readily believe that in such a case recovery would be promoted by a judicious abstraction of blood. I have twice seen symptoms, so closely resembling those of acute spinal meningitis as not to be distinguished from them, disappear coincidentally with the occurrence of local haemorrhage, once from piles, once in the form of menstruation; and I can well believe that a similar result might be furthered by the application of leeches around the anus or to the cervix uteri—to these parts rather than to the back, because their vessels would seem to communicate more directly with the deep spinal vessels. It is very probable, however, that the time will soon pass in which depletion in any form, or depressing remedies of any kind, are required, and that the indications will rather be towards brandy, or ammonia, or ether, than towards the remedies which have been mentioned, for all acute diseases of the spinal cord would seem to have a rapidly devitalizing influence upon the system. In acute cases the catheter may be necessary to empty the bladder; in chronic cases, aching and stiffness of the limbs may point to friction and shampooing as likely means of relief. In every case there is sure to be some peculiarity to which attention must be directed if the plan of treatment be all that it ought to be; and, in short, every case must be treated on its own merits.

II. MYELOITIS.

Myelitis, or inflammation affecting the substance without involving the membranes of the cord, is a well-defined and not very uncommon disease. It may occur in an acute or in a chronic form: it may be general or partial: and, to say the least, its features are quite as well marked and distinctive as those of spinal meningitis.

1. Symptoms.—As an instance of acute myelitis, and as a text for what has to be said under this head, I take the notes of the case of a hospital patient under my care not long ago.

Case.—Charles K., a draper's assistant, twenty-six years of age, unmarried, a patient admitted into the National Hospital for the Paralysed and Epileptic on the 9th of June, 1864.

(a) The chief symptoms complained of are paralysis and anaesthesia below the waist, a disagreeable feeling of tightness around the waist, inability to pass water, involuntary stools, and pain in the left side of the chest. Above the waist, the power of movement and the power of sensation are natural; below the waist, all the voluntary muscles are entirely paralysed, and the sensibility to pain, to tickling, to differences of temperature, as well as to touch, are completely lost. Pressure along the spine is felt above the point to which the anaesthesia reaches, but not below it, and where felt the patient bears it without wincing. In other words, there is no tenderness on pressure in that part of the spine which preserves its sensibility. The feeling of warmth produced by passing a sponge soaked in moderately hot
water along the spine is felt above the point to which the anaesthesia reaches, but not below it, and, where felt, the feeling of heat is natural, except at the line of junction between the sensitive and insensitive parts, and there the feeling produced is that of burning. Moreover, the warm sponge produces the same feeling of burning all around the body in the course of this line of junction, and thus it is plain that this local over-sensitiveness to heat is not confined to the spine. No reflex movements are produced by tickling the soles of the feet. The ale nasi work very much, the lips are somewhat dusky, the lower intercostal muscles are motionless and the accessory inspiratory muscles are in full work, the air passages (especially on the left side) are loaded with phlegm, the pulse is hurried and weak, the skin is moist and somewhat cooler than natural, and the voice is so low as to be scarcely audible. A cough of the feeblest sort is almost incessant, but the expiratory power at command is altogether insufficient to bring about the expectoration which is so much wanted. All appetite is gone, but food can be taken, and there is no thirst, or none to speak of. The urine, which is acid, and of the specific gravity of 1015, has to be drawn off by the catheter. There is no priapism. A stool has just passed without the patient being aware of it until his nose took account of the accident.

(b) A week ago, on awakening from a short nap, the patient found that his toes had gone to sleep, and that he had to "take long breaths." Instead of passing off, the feeling of tingling spread from the toes to the feet, from the feet to the legs, from the legs to the thighs, until it reached the seat, becoming less and less endurable as it spread, and being at last accompanied by a feeling of tightness around the waist and around the left instep, and by a state of restlessness which made it impossible to sit still for more than a moment at a time. After suffering in this way for a couple of hours, an attempt to pass water, which failed altogether, was followed by an almost intolerable uneasiness at the end of the penis, and by a sudden weakness in the legs which made it necessary to remain on the bed upon which he had fallen. Up to this time there had been no difficulty in standing or walking, not even in going up and down stairs. A friend of the patient's now present says:—"I saw him on the evening of the day on which he was attacked, a couple of hours or so after he had been obliged to take to his bed. I thought he was suffering from severe rheumatic pains. For some hours those pains were excruciating. I had never before seen any one suffer so much. He tossed about in dreadful agony; he roared out with pain often, and when not roaring, he groaned." Having thus passed seven or eight miserable hours, he fell asleep and slept until breakfast-time next day. Upon waking in the morning he could neither move his legs nor empty his bladder; he had lost all feeling below the waist, and all the miserable feelings which had kept him in a state of continual unrest before he fell asleep were gone. On inquiring whether these feelings were of the character of pain,
he says, "No, not exactly, worse than pain, one continued numb
stinging feeling, as if the parts were asleep," so that the friend's
words which have just been quoted must be taken as meaning not
exactly what they seem to mean in this particular. For the six
days preceding his admission to the hospital a state of imperfect
priapism was apt to come on of itself, or to be brought on by intro-
ducing a catheter to draw off the water, and this is the only point
remaining to be noticed here, for in other respects the condition seems
to have remained stationary, except, perhaps, that a little ground
was lost every day.

The patient seems to have come of a healthy family, and, though
never very strong, to have himself always enjoyed tolerably good
health. He was confined to the house for a few days about two
months ago for "influenza," and this is the only illness of any kind
he remembers to have had. He says, "I was fatigued by a long walk
on the day I was taken ill, and for a month and more I had felt more
tired in my back and legs than usual in an evening, and more rheu-
matic—less up to the mark;" and also, "My back always ached at the
end of the day's work, and so did my legs, and I was always glad to
go to bed soon, for in bed I was comfortable:" and besides these
statements there appears to be nothing at all calculated to throw light
upon the history of his present malady.

Jan. 10.—Early this morning, after a sleepless night, a severe rigor
commenced in the right arm, and then extended first to the back, and
afterwards to the whole body. This rigor continued a full quarter of
an hour, and was followed by profuse perspiration. During its con-
 tinuance the paralysed parts were very cold: after it had ceased the
warmth returned, and brought with it a considerable mitigation of the
cough and trouble of breathing. Indeed, after the establishment of
reaction, difficulty of breathing ceased to be an urgent symptom, except
for a moment or two after waking from an occasional and very brief
dose. The anaesthesia in the trunk has mounted full an inch higher
since yesterday, but it has not extended to either of the upper
extremities. Priapism occurs frequently. The pulse is 150, the
respirations are 36 in the minute.

Jan. 11.—There has been no sleep in the night. The engorged
condition of the lungs has gained headway, and the harassing suflo-
cative cough has returned. Hiccough is frequent and distressing.
Once during the day the passage of the catheter was obscurely felt,
this being the first sign of feeling in this part since the commencemen-
t of the illness. The urine is decidedly acid. The electro-contract-
tility and electro-sensibility of the paralysed muscles is annihilated.

Jan. 12.—For the last twenty-four hours the increased difficulty of
breathing attending sleep has caused the patient to wake immediately
if he for a moment forgot himself. "I can't breathe except I keep
awake," he said in a voice scarcely audible; and also, "I hope I
have not long to live." The passage of the catheter is still obscurely
felt, and the escape of flatus and fæces is perhaps not so entirely
unfelt as it has been since the commencement of the illness. In other parts the anaesthesia, like the paralysis, remains as complete as ever. The urine is still acid, distinctly so. For the last twenty-four hours there has been no priapism, and scarcely any cough. At present hiccup is almost constant, the pulse is fluttering, the hands are cold and clammy, and, in short, the signs of the near approach of death are not to be mistaken.

Jan. 13.—The patient lingered through the night, and died about daybreak; his mind unhappily remaining too clear to the very last.

The notes of the post-mortem examination are as follow:—

Jan. 14, 4.30 P.M.—Rigor mortis is fully established everywhere. The dependent parts present considerable signs of suggillation, especially along the course of the spine, and there is incipient breaking of the skin on both the nates. The arachnoid covering of the cord everywhere is clear, smooth, and without any traces of inflammation. The outside of the lumbar enlargement is curiously nodulated. On making a longitudinal section, the whole substance of the cord, from the brachial enlargement to its inferior extremity, is found to be of a yellowish red colour, softened in a remarkable manner, and in the lumbar region almost like cream in consistence. Several small patches of extravasated blood are scattered in the softened structure, these patches being undefined in outline, more numerous in the lumbar than in the dorsal region of the cord, and situated chiefly in the posterior columns. The red discoloration which has been mentioned is most marked in the neighbourhood of these patches. The examination did not extend further, the friends of the patient consenting to it only on condition that it should be thus partial.

Jan. 15.—On examining some portions of the diseased cord under the microscope, the natural structure is found to be altogether broken down, and mixed up with blood corpuscles, exudation granules, and (in fewer numbers) pus-corpuses.

With a view to arrive at a knowledge of the general features of myelitis, I select as the principal points for comment in this particular case the following:—Paraplegic anaesthesia, ushered in by tingling or some similar sensation in the parts which eventually became anaesthetic; paraplegic paralysis, ushered in by uncontrollable restlessness; a disagreeable feeling of tightness around the waist and elsewhere; absence of pain in the spine or extremities—of pain produced by movement especially; absence of trismus and other spasmodic or convulsive symptoms; retention of urine; involuntary stools; absence of pain on pressure (spinal tenderness) in any part of the spine; increased sensibility to differences of temperature, by which moderately warm or iced water gave rise to a feeling of burning instead of the natural feeling over the vertebra which marks the upper limit of the myelitis; annihilation of reflex excitability in the paraplegic parts; priapism; acidity of urine; comparative voicelessness; impeded respiration; engorgement of lungs and other viscera; tendency to bed-sores; loss of electro-contractility and
electro-sensibility in the paralysed muscles; absence of "head-symptoms;" absence of fever.

Paraplegic anaesthesia, ushered in by tingling or some similar sensation in the parts which eventually became anaesthetic.—In this case the anaesthesia was developed suddenly during the first night's sleep; it was deep-seated as well as superficial; it implicated the sensibility to pain, tickling, and differences of temperature, as well as that of touch; it had a paraplegic distribution; and this would seem to be the rule in cases of acute myelitis. In chronic cases it is developed more gradually, and it may not extend to all the various forms of sensibility; moreover, it may in some instances be quasi-hemiplegic instead of paraplegic; but the rule in acute cases appears to be what it is found to be in this. The anaesthesia seems to be usually ushered in by tingling or by some analogous sensation, disagreeable enough, but not amounting to actual pain. In this particular case the preliminary sensation was not pain, but an unbearable "numb stinging," as if the parts were asleep, with a feeling of tightness around the waist, and around one of the insteps. In acute cases it is right to speak of anaesthesia as ushered in by tingling or some similar sensation, but scarcely so in chronic cases. In chronic cases, indeed, these anomalous sensations may never exactly come to an end, because in these cases the destruction of sensibility may never get beyond numbness—may never reach nearer to anaesthesia, that is to say, than dysæsthesia.

Paraplegic paralysis, ushered in by uncontrollable restlessness.—The paralysis was thus ushered in in the case under consideration, and in two similar cases which have come specially under my own notice—by restlessness, and not by any more marked tremulous, convulsive, or spasmotic symptom. Neither does it appear that a different rule obtains in other cases, acute, sub-acute, or chronic. In the great majority of cases, no doubt, the paralysis has a paraplegic form, but in a few cases it is not so. In the great majority of cases, the paralysis is accompanied by numbness, but not absolutely in all. Sometimes, for example, as in the case in which the paralysing lesion is limited to a portion of one lateral half of the spinal cord—the case about which enough was said in the preliminary remarks—there is paralysis without numbness on one side, and numbness without paralysis on the other side. Several cases of this kind are on record, and the number of them which I have myself met with is sufficient to convince me that they are scarcely to be looked upon as out of order and exceptional. Sometimes, also, as in the case where the paralysing lesion is confined to a portion of one of the anterior columns, the paralysis may be divorced from numbness, and not only so, but it may be hemiplegic in its distribution; and in such a case it may, in fact, be no easy matter to say whether it is dependent upon a cerebral or upon a spinal cause. In some cases, also, the paralysing lesion may be so localised as to affect only, or chiefly, an arm on one side and a leg on the other side. Usually, however, the
paralysis is distinguished by being associated with numbness, and by being paraplegic in its distribution.

A disagreeable feeling of tightness around the waist and elsewhere.—A feeling of circular constriction around the trunk, or around some part of an extremity, around the trunk especially, is so common as to deserve to be considered as an almost constant symptom in myelitis. I do not recall a case, acute or chronic, in which it was entirely absent at all times.

Absence of pain in the spine and extremities—of pain produced by movement more especially.—In chronic cases of myelitis, Dr. Brown-Séquard speaks of "a constant pain in the part of the spine corresponding to the upper limit of the inflammation of the cord" as a characteristic symptom; but I question very much whether this statement is in accordance with well-sifted clinical facts. Pain, either in the spine or elsewhere, is not mentioned, for example, in the nineteen cases, acute and chronic, given by Ollivier, except in three, and of these three the myelitis was complicated with meningitis in two, and in the one remaining the symptoms justify the presumption (and there was no post-mortem examination to set it aside) that the same complication existed. At any rate, it is certain that there is not in uncomplicated myelitis that severe pain in the back and limbs which is brought on or aggravated by movement in spinal meningitis.

Absence of spasmodic symptoms.—Ollivier speaks of continuous contraction of the limbs as being met with "assez ordinairement," in chronic myelitis; but the cases cited by this excellent observer do not substantiate this statement. Thus, out of nineteen cases of myelitis, complicated and uncomplicated, acute and chronic, there are three only in which these contractions were present, and not one of the three can be cited correctly as a case of myelitis. In one of the three (No. 87) the sensibility was intact, and the disease of the cord confined almost exclusively to the anterior column; in another (No. 93) there was obtuse sensibility, and the disease was chiefly in the grey matter; and in the third (No. 94) sensibility remained, and there was no post-mortem examination to show what the disease in the cord really was. In each one of these cases, also, there were "head-symptoms" which do not figure in uncomplicated myelitis. Again, prolonged contraction of the extremities is a not unfrequent symptom in cases in which there is neither myelitis nor spinal meningitis—cases which properly come under the head of "spinal irritation," and about which more will have to be said in another section of this article. In these cases the contraction, instead of pointing to inflammation of the cord or its membranes, is really no more than one of a series of so-called hysterical phenomena. It is a sign of functional disorder only, and that it is so is evident (these among other proofs) in the sudden and complete way in which it passes off, as well as in the fact that it does not leave behind it any permanent organic traces. It depends, as it would seem, upon a state of irritation in some part of that track in which irritation gives rise to prolonged spasm—a state issuing, it
may be, now and then in inflammation, but in itself, so far as the condition of the blood-vessels is concerned, diametrically opposed to inflammation. Nay, even in those exceptional cases of myelitis in which there is increased reflex excitability in the paralysed limbs, it is difficult to connect these spasmodic symptoms with the inflammation. Dr. Brown-Séquard says: “When the dorso-lumbar enlargement is inflamed, reflex movements can hardly be excited in the lower limbs, and frequently it is impossible to excite any. On the contrary, energetic reflex movement can always be excited when the disease is in the middle of the dorsal region, or higher up.” And again, when speaking of the reflex convulsions which may happen in the cases where the inflammation is in the middle of the dorsal region or higher up, he says, “Convulsions do not take place at the beginning of the inflammation, but some time after, and they recur by fits for months and years after.” And this is precisely what happens. In a word, the truth would seem to be that these reflex spasmodic movements must be referred, not to inflammation in the lumbar enlargement of the cord, nor yet to inflammation higher up in the cord; for in this case, to repeat what has just been said, “the convulsions do not take place at the beginning of the inflammation, but some time after, and they recur by fits for months and years after.” They happen, as it would seem, after the inflammatory disorganization has interrupted the continuity of the cord, and produced a state of things analogous to that of a guinea-pig, or other animal, whose spinal cord has been cut across experimentally—a state of things of which increased reflex excitability in the paralysed parts is one of the consequences. Nor is a different conclusion to be drawn from the occasional presence in the paralysed muscles of a state which is analogous to or identical with the “late rigidity” of Todd. This “late rigidity” is very different to “early rigidity.” In “early rigidity” the electro-motility of the muscles is increased, and the muscles relax during sleep, and to a less degree under the influence of warmth. The muscular contraction is evidently of the nature of spasm. In “late rigidity,” on the contrary, the muscles are wasted, their electro-motility annihilated, and sleep or warmth do not tell in causing relaxation. This form of muscular contraction, indeed, if not identical with rigor mortis, is, as it would seem, more akin to this state than to spasm. In the case of myelitis which serves as my text, there was none of the painful muscular rigidity produced by movement which is so prominent a symptom in spinal meningitis. There was, indeed, no spasmodic symptom of any kind, with the exception of the rigor which ushered in the extension of the disease on the day after the admission of the patient to the hospital. And this absence of spasmodic symptoms would seem to be the rule in all cases of myelitis, acute or chronic. In children, it is true, myelitis may be ushered in by convulsion—in which case the convulsion manifestly represents the rigor which may usher in myelitis in adults, and as manifestly belongs to the precursory stage of irritation, and not to
the state of actual inflammation—but even in children, unless there be some meningeal complication along with the myelitis, this preliminary convulsion would seem to be a rare phenomenon.

Want of control over the bladder.—This appears to be the earliest as well as the most constant of the symptoms of myelitis. It usually depends upon paralysis of the accelerator urinæ and compressor urethrae, but now and then it would seem to be connected, for a while at least, with a state of spasm in the latter of these muscles, in which case the dribbling away of the water or the introduction of a catheter will sometimes produce marked reflex spasms in the legs. I remember one case—a case in which the myelitis seemed to have interrupted the continuity of the cord high up in the back—where an attempt to use the catheter often gave rise to strong reflex spasms in both legs, and to a state of spasm in the urethra strong enough to prevent the passage of the instrument.

Want of control over the rectum.—In myelitis paralysis of the sphincter ani is usually associated with paralysis of the accelerator urinæ and compressor urethrae. Now and then also, the sphincter ani, instead of being paralysed, may be in a state of reflex spasm: thus, in the case to which I have just referred, the administration of an enema was sometimes rendered impossible by the spasm set up in the sphincter ani and in the femoral muscles by the pipe.

Absence of local spinal tenderness.—As in spinal meningitis, so in myelitis, absence of tenderness on pressure in any part of the spine would seem to be the rule, and not the exception. Ollivier, speaking of pain in the back in myelitis, says, "Elle n'est jamais rendue plus aiguë par la pression," and my own experience in the matter is, without question, to the same effect.

Altered sensibility to heat and cold by which a feeling of burning is felt when a sponge soaked in moderately warm water or a piece of ice is applied to the spine immediately above the seat of inflammation.—Several years ago it was pointed out by Mr. Copeland that, when a sponge soaked in water a little above the temperature of the blood was passed along the spine from above downwards, it gave rise to the natural feeling of heat until it reached the inflamed part, and that then this feeling changed to that of burning: and more recently Dr. Brown-Séquard has shown that a similar result is arrived at by passing a piece of ice down the spine, the natural feeling of cold being felt until the inflamed part is reached, and then an unnatural feeling of burning. In many cases, no doubt, all this would seem to be quite true, but not in all, perhaps not in the majority; and therefore it is impossible to look upon the feeling of burning thus produced as more than an occasional occurrence in myelitis.

Annihilation of reflex excitability.—What has to be said under this head has been anticipated when speaking of the absence of spasmodic symptoms in myelitis. It has indeed been seen to be the rule for all
reflex movements to be annihilated or greatly weakened in the paralysed parts, and that the apparent exceptions to this rule are to be explained, not by referring the increased reflex movement to myelitis, but by supposing the inflammatory disorganization to have interrupted the continuity of the cord and produced a state of things analogous to that of a guinea-pig whose cord has been cut across for experimental purposes.

_Diminution of electro-motility and electro-sensibility in the paralysed muscles._—Except in those few, very few, cases in which the reflex excitability is increased, the electro-motility and electro-sensibility of the paralysed muscles are invariably diminished in myelitis. Where the reflex excitability is increased the electro-motility may also be increased, and so also may the electro-sensibility, but more generally the increase in the former property is without a corresponding increase in the latter. The paralysed muscles are wasted in almost all cases, and relaxed also, except in those few cases in which the paralysis has lasted for a very long time and become associated with that state of "late rigidity" which, sooner or later, is always found to seize upon paralysed muscles. Marshall Hall noticed the impairment of irritability in spinal paralysis, and was of opinion that an opposite state of things existed in cerebral paralysis. As was pointed out by Todd, however, this supposed distinction between spinal and cerebral paralysis does not hold good, the simple fact being that in the great majority of cases of cerebral paralysis the irritability of the paralysed muscles, instead of being increased, is either not materially altered or else more or less diminished—most generally diminished in a very marked degree. In a word, the investigations of this very accomplished physician show most clearly that in cerebral paralysis the irritability of the paralysed muscles is only increased in those comparatively few cases in which the paralysis is associated with "early rigidity."

_Priapism._—It is difficult to attach any diagnostic value to this symptom. As in acute spinal meningitis, so in acute myelitis, it is sometimes present and sometimes absent, less frequently present in the latter affection perhaps than in the former.

_Frequent alkalinity of the urine._—Dr. Brown-Séquard says: "One of the most decisive symptoms in myelitis is alkalinity of the urine. There is no patient attacked with myelitis in the dorsal region of the cord whose urine is not frequently alkaline. At times, especially after certain kinds of food, the urine is acid, but the alkalinity soon returns." And no doubt the urine is very generally alkaline in myelitis, especially in those cases in which the paralysis of the bladder has led to secondary disease of this organ; at the same time, as in the case under consideration, the urine is too often acid to make it possible to insist upon alkalinity of the urine as a necessary feature in myelitis.

_Dyspnæa._—Difficulty of breathing was a very urgent symptom in the case which serves as my text, and so it must be in every case
where respiratory muscles are so gravely implicated in the paralysis, and where the lungs are so much engorged. Indeed, the usual way in which myelitis proves fatal is by compromising the sufficiency of the respiration. Now and then, especially when chronic inflammation affects the higher regions of the cord, the difficulty of breathing may occur in paroxysms not unlike those of asthma, but usually the difficulty shows itself rather as simple shortness of breath,—shows itself in a way which supplies another proof of the absence of the spasmodic element in the history of myelitis.

*Want of power in the circulation.*—There is little or no sympathetic fever in the most acute form of myelitis; and in the ordinary chronic forms, the feeble pulse, the edematous condition of the paralysed extremities, the disposition to passive engorgement in the lungs and elsewhere, and other symptoms of like meaning, show very plainly that the state of the circulation is eminently asthenic. It would even seem as if there were something in the very fact of myelitis which has a positive influence in subtracting power from the circulation—which exercises a devitalizing influence upon the system generally.

*A tendency to bed-sores, wasting, and other signs of defective nutrition in the paralysed parts.*—Sooner or later, generally at a very early date, a marked disposition to bed-sores in places where paralysed parts are subjected to pressure is apt to show itself in myelitis, and so also are other signs of defective nutrition in the same parts, such as edema, dryness and seariness of the skin, and a wasted and flabby state of the muscles. So marked, indeed, is this impairment of nutritive power in these paralysed parts, that it is only by very great care that bed-sores and the other lesions which have been mentioned can be prevented.

*Absence of head-symptoms.*—In cases where acute myelitis attacks the higher portions of the cord, there may be, and there in all probability will be, various "head-symptoms"—vertigo, singing in the ears, grinding of the teeth, delirium, convulsion, coma, or others—but these cases, to say the least, are not common. Whether acute or chronic, indeed, myelitis is much more apt to attack the lower portions of the cord than the upper, in this respect differing from spinal meningitis; and when it attacks the upper portions of the cord, and its symptoms present cerebral complications, the chances are that the case is not simple myelitis, but myelitis with more or less spinal meningitis in addition.

When the cord is affected generally, the symptoms of myelitis will not differ greatly from those which are present in the case which has been given; when the inflammation is more localized, the symptoms will vary accordingly. If, for example, the inflammation be limited, as it usually is, to the lumbar enlargement of the cord, the level of the paralysis and anesthesia will be proportionally low down; and if the extreme end of the cord only be affected, it is possible that the legs may escape altogether, and the bladder and anus be alone at fault. As indeed the level of the inflammation in the cord falls or rises, so must the level of the paralysis and anesthesia fall or rise also.
Exaggerated reflex movements in the inferior extremities will also (in all probability) be associated with the paralysis and anaesthesia, if the lower parts of the cord be sound and the inflammation confined to a portion of the cord higher up. Again, the symptoms which are present when the inflammation is limited to a part only of the thickness of the cord will be different in many respects from those which are met with when the whole thickness is affected. If, for example, a portion (the upper half-inch of their course excepted) of the anterior columns be affected solely, there would be paralysis without anaesthesia; or if the posterior columns were alone affected, there might be in-coordination of movement and some hyperesthesia instead of paralysis and anaesthesia. In short, the variations of symptoms, which occur where myelitis is restricted to particular parts of the cord, can only be properly intelligible to him who has clear notions respecting those physiological matters which were glanced at in the preliminary remarks,—which were then glanced at chiefly in order to avoid perplexing physiological digression and discussion in the present place among others. I will, therefore, assume that what was said in the preliminary glance at some points in the physiology of the spinal cord, will serve to explain sufficiently the variations of symptoms which may be expected to exist when the integrity of particular parts of the spinal cord is destroyed by myelitis or in any other way: and, for the rest, I will only say that myelitis may be chronic and sub-acute as well as acute in its course, and that these several varieties interblend insensibly the one with the other.

2. Post-mortem Appearances.—Myelitis may result either in softening or in hardening of the spinal cord. Most frequently the cord is broken down, reduced to a yellowish or reddish cream-like consistence; the colour, derived from the admixture of pus or blood-corpuscles, being more yellow or more red according as the one or the other of these corpuscles predominate. This softening may affect the whole thickness of the cord, or certain parts more than others, the grey matter especially; it may extend from one end of the cord to the other, or it may be confined to certain regions, in which latter case the part most likely to be affected is the lumbar enlargement; and it would often seem to have its starting-point in the central grey matter, which is the most vascular part of the cord. In the first stage of myelitis this central grey matter has a rosy or vinous tinge, which is not natural to it; it is plainly more vascular than it ought to be; and, in short, it has undergone the very same change which is met with in the grey matter of the brain in encephalitis. Sometimes the spinal cord is considerably swollen, and sometimes the surface may have a nodulated appearance in certain parts, from the membranes having yielded at these points to the blood which may have escaped, or to the pus which may have collected, underneath. Not unfrequently small collections of blood are met with in the softened nerve tissue, especially in the position
of the central vessel, so that the first impression upon opening
the cord may be that of haemorrhage rather than that of myelitis. 
One remarkable feature of inflammatory softening, says Dr. Todd, is 
that "it exhales a marked odour of sulphuretted hydrogen, and so 
indicates a rapid advance of putrefaction;" and again, "It is a fact 
deserving of attention that the substance of the spinal cord softens 
very rapidly after death, the lapse of half an hour, during which the 
nervous substance has been exposed to the air, often producing a 
manifest alteration." Indeed, there are reasons for believing that the 
amount of disorganization met with in the cord after death does not 
necessarily represent the exact amount which existed during life, and 
that a cord which is found to be broken up after death almost 
utterly, may have retained during life sufficient integrity to allow of 
the transmission of certain sensitive and motor impressions. On 
this view the return of slight sensation in the urethra and rectum 
shortly before death, and the preservation of the power of moving 
and feeling in the arms, which were noticed in the case which serves 
as my text, are not altogether unintelligible.

Induration, the other result of myelitis, is looked upon by some 
as a stage always preceding softening, but it would rather seem to 
mark, as Ollivier supposed, a less acute form of inflammation. In it 
the fibrinous products of the inflammation seem to have been more 
organizable. The cord thus indurated varies greatly in appearance; 
it may be almost as pale, bloodless, crisp, and hard as cartilage; it 
may be more or less red and vascular, and proportionably softer; and 
in either case, when examined under the microscope, its proper 
tissues are found to be broken up and destroyed almost as effectually 
as they are when the cord is softened. A cord which is indurated 
has usually a shrunken appearance, but it may be swollen consider-
ably. There is no doubt an induration of the cord, as well as a 
softening, which cannot be referred to myelitis, and which must not 
be confounded with that which is the result of inflammation; but I 
must not stay to point out the differences, nor yet to do more than 
say that in myelitis there will in all probability be found, in addition 
to the signs which have been indicated, engorgement of the lungs, 
kidneys, and other viscera, possibly more marked vascular changes, 
with bed-sores, œdema, dry and scurfy skin, wasted muscles, and other 
signs of defective nutrition in the paralysed parts.

3. Causes.—Nothing very much to the point can be said under this 
head, and the only remark I feel called upon to make is this, that as 
in spinal meningitis a rheumatic habit has been found to figure more 
or less conspicuously among the causes of the malady, so here a like 
position would seem to be due to a strumous habit. I would also 
confess to a growing impression that myelitis may not unfrequently 
be connected more with excess of sexual indulgence than with any 
other single cause, but I cannot say that this impression has yet 
taken the form of a definite conviction.
4. Diagnosis.—In dealing with the symptoms of myelitis it has been shown that these are very different from those of spinal meningitis—so different as to make it difficult to confound them, if only moderate care be taken in realizing them. In spinal meningitis the most prominent symptom is pain in the back and extremities, produced or aggravated by movement; in myelitis pain of any kind has scarcely a title to be reckoned among the symptoms, pain produced by movement certainly not. In spinal meningitis the sensibility is somewhat exalted, in myelitis it is abolished. In spinal meningitis there is muscular weakness, and the muscular movements are fettered by pain, but there is no true paralysis; in myelitis paralysis is the symptom of symptoms. In spinal meningitis there is a state simulating trismus and tetanus, a state of muscular rigidity half voluntary as to its character, of which the object is to prevent certain movements which give rise to pain; in myelitis the muscles are limber, and there is usually an utter absence of any symptom akin to tremor, convulsion or spasm.

Nor need the symptoms of common paraplegia (resulting from chronic myelitis) be confounded with those of locomotor ataxy. In common paraplegia there is paralysis more or less marked of the lower extremities, and the nutrition and irritability of the paralysed muscles are, as a rule, unmistakably impaired; not so in locomotor ataxy. In common paraplegia the paralysis extends to the bladder and sphincter ani, and the sexual power is greatly weakened, if not altogether abolished; not so, or not to anything like the same degree, in locomotor ataxy. In common paraplegia the characteristic neuralgic pains of locomotor ataxy are wanting, and numbness is nothing like so prominent a symptom as in the ataxic disorder. In common paraplegia, where walking is possible, the gait—instead of being precipitate and staggering, the legs starting hither and thither in a very disorderly manner, and the heels coming down with a stamp at each step, as in locomotor ataxy—is: hampered and slow, each leg being brought forward with evident difficulty, even with the help of an upward hitch of the body on the same side, and the part of the foot first coming in contact with the ground being, as a rule, not the heel, as in ataxy, but the toes. In common paraplegia impairment of sight or hearing, or strabismus, or ptosis, or injection of the conjunctive, or contraction of the pupils, frequent if not constant symptoms in locomotor ataxy, form no part of the history. In fact, in these respects, and in others of minor importance which might be mentioned, the histories of common paraplegia and locomotor ataxy are so different that it is not easy to see how, with only a moderate amount of care, the two disorders can be confounded.

Now and then, it is true, instances occur in which it is not so easy to distinguish this gait of common paraplegia from that of locomotor ataxy—cases in which the weakened muscles contract somewhat spasmodically when put in action, and in which there is often reason to believe that the membranes as well as the substance of the
cord are affected, but, as a rule, the gait in common paraplegia
and in locomotor ataxy is sufficiently characteristic to make it diffi-
cult to confound these two affections.

In cases where the myelitis is confined to the posterior columns
of the cord, the symptoms will be those of locomotor ataxy rather
than those which have been ascribed to myelitis; for, so far as the
production of symptoms is concerned, it is of no moment whether
the disease disorganizing the posterior columns be inflammatory or
non-inflammatory, acute or chronic; and in other cases of local
myelitis symptoms are sure to be present which cannot fail to lead
to a correct diagnosis, if what was said in the preliminary remarks
upon the physiology of different parts of the spinal cord be borne in
mind in interpreting them. Indeed, with what is now known of the
physiology of the spinal cord, there need not be much difficulty in
determining the whereabouts of local mischief in the cord.

That myelitis cannot well be confounded with other spinal
disorders—spinal congestion, tetanus, spinal irritation, and the rest—
will be seen readily enough when a clear idea of these disorders has
been realized, and only then; and this being the case, it is best to
waive these questions in diagnosis until the fitting opportunities for
dealing with them present themselves.

5. PROGNOSIS.—Acute myelitis affecting any considerable extent of
the spinal cord is, without doubt, a very grave disorder. It may be
fatal in fifteen or twenty hours, and it is seldom that life is prolonged
beyond the end of the second week. Instances of recovery are on
record, it is true, but these are very few in number, and of them there
is, perhaps, no single one in which the correctness of the diagnosis
may not be impugned. Even chronic myelitis is a very grave
disease; for though life may be prolonged, especially where the disease
is confined to the lower part of the cord, the mischief once done
seems to be in a great measure irremediable. At the same time it is
only right to say that of late years the results of treatment have been
much more satisfactory, and that it is possible now to hope where
there was little room for hoping formerly.

6. TREATMENT.—There appears to be little room for what is called
active treatment even in acute myelitis. The inflammation is
evidently of a very low type, and, reasoning from what is known of
its beneficial action in erysipelas and in some other low forms of in-
flammation, it seems to me that sesquichloride of iron would be likely
to be of more real service than iodide of potassium. Indeed, I should
be disposed, until I know of a better plan, to trust chiefly to full
doses of this preparation of iron, to food and wine in no stinted quan-
tities, and to the position recommended by Dr. Brown-Séguard for
draining away blood from the spine—a position in which the patient
is made to lie upon his abdomen or side, with his hands and feet in
a somewhat dependent position.
DISEASES OF THE SPINAL CORD.

With respect to the good or bad effects of belladonna, or ergot, or strychnia, it is not very easy to arrive at a satisfactory conclusion. I agree with Dr. Brown-Séquard in thinking that belladonna and ergot may have the effect of counteracting a hyperæmic condition by causing contraction in the vessels, and that the vessels of the spinal cord may, perhaps, respond most readily to their action, but not as to the indication for employing these remedies. Pain and spasm are, to Dr. Brown-Séquard, signs of hyperæmia: to me, except the pain produced by movement, they are signs of irritation only—of a state which is connected, not with hyperæmia, but with anæmia, a state of contraction of the vessels which may pass into relaxation, but which need not necessarily do so; and, therefore, to me pain and spasm, instead of being indications for the employment of belladonna or ergot, are in very deep contra-indications. Nor can I agree in thinking that strychnia acts by increasing the amount of blood in the spinal cord and in its membranes, and that on this account it is contra-indicated in hyperæmic conditions of these parts. Strychnia, without doubt, produces tetanic spasms and other unequivocal signs of spinal irritation, but it is begging the question altogether to suppose that the strychnia increases the amount of blood in the cord and its membranes, that this increase of blood augments the vital activity of the cord, and that the spasms and other signs of irritation attest this augmentation of vital activity. Indeed, so far from this being a necessary conclusion, all the evidence pointed out in the preliminary remarks, as it seems to me, points in the opposite direction, and connects the state of irritation of which the spasms are the signs, not with a hyperæmic condition, but with an anæmic; and most assuredly I know of nothing in the history of myelitis or spinal meningitis which is calculated to invalidate this conclusion. Moreover, the investigations of Dr. Harley upon the action of strychnia upon the blood go to show that this action is really equivalent to loss of blood in that it directly interferes with the proper arterialization of the blood. In a word, I cannot find any fundamental difference between the action of belladonna, ergot, and strychnia upon the blood-vessels, neither can I understand why strychnia, properly used, might not be of as much service as belladonna or ergot in lessening a hyperæmic condition of the cord. For my own part, however, I confess to a feeling which makes me hesitate to employ either belladonna, or ergot, or strychnia in myelitis, or in any analogous condition, until I know more of their action, or until I have more unequivocal empirical evidence of the good resulting from their use.

In chronic cases the one grand indication of treatment, as it seems to me, is to improve the nutrition of the cord, and the medicine best calculated to carry out this indication, cod-liver oil, sesquichloride of iron, phosphorus in one form or other, arsenic, and possibly bichloride of mercury, which latter preparation, when properly used, I believe to be tonic and antiseptic in a high degree, and in many respects much
more analogous in its action to arsenic than to any of the proto-
compounds of mercury in common use.

The local means for promoting the recovery of the paralysed muscles
are certainly of not less importance than the general means, possibly
of much greater importance, and these local means are very various.
The efficacy of frictions and shampooings appears to be indisputable.
The efficacy of proper movements can only be doubted by those who
are unacquainted with the results arrived at by the "movement cure,"
and by systematic movements of one kind or another, with or without
the help of mechanical apparatus. The efficacy of faradisation has
been abundantly proved, and there is good reason to believe that this
is not the only mode of using electricity which will be of great ser-
vice; that in fact statical positive electricity, or the interrupted gal-
vanic current, or the application of the galvanic current in such a
way that the paralysed nerve is acted upon chiefly by the positive
pole—a mode of using electricity about which I have spoken elsewhere,
and which I have used extensively during the last three or four years—
will often be of great service in proper cases. Indeed I should think
that the treatment was wanting in very essential particulars if these
local means, one and all, were not associated with the general means
of treatment, and employed systematically and perseveringly; and
especially I should regard it as a great blunder if these local means
were deferred so as to allow the paralysed muscles to lose what
when lost is not easily recovered,—that is, their irritability and healthy
organization.

There are also other local measures which are of great service in the
treatment of paralysis, and one of these to which I am disposed to
attach especial importance is to protect the paralysed parts from cold.
In many cases, as is well known, these paralysed parts are cool, and
in not a few instances, where the paralysis is incomplete or associated
with early rigidity, this paralysis and rigidity is greatest when these
parts are coldest. For example, it is no uncommon thing for a par-
tially hemiplegic patient whose paralysed fingers are contracted, stiff,
and altogether useless when acted upon by cold, to be able to open
his hand and use his fingers with comparative freedom when the
hand is warm in bed, or placed in a warm bath, or held a while before
the fire. At any rate, I have long been satisfied that the well wrap-
ing up of the paralysed parts in woollen or silken or India-rubber
coverings is an important help in treatment.

It would also seem that good of the same kind, much good, may be
got from an exhausting apparatus made on the principle of Junot's
boot. The effect of such an apparatus, properly used, is to make the
paralysed parts warmer at the time, and to enable them to preserve
this warmth for a considerable time,—to produce a change in the
circulation, which must have a good effect upon the nutrition and
irritability of the paralysed muscles.

It is also more than probable that electricity may be of service in
improving the condition of the circulation in the paralysed parts, for
an increased feeling of warmth in the paralysed parts is the result of faradizing these parts, or of electrifying them with statical electricity; indeed I have been more than once disposed to think that the beneficial effects of electricity in the resuscitation of paralysed parts are as much brought about indirectly by changes produced in the circulation as by changes wrought directly in the nerves and muscles.

As regards the necessity for tenotomy and the use of orthopaedic apparatus in certain cases, it is difficult to speak to any good purpose. I shall have to refer to these subjects when speaking of infantile paralysis, and here I will only say, that in many cases, in children especially, the cure will be greatly facilitated by tenotomy and orthopaedic apparatus, and that it is not always easy to decide between the cases in which these measures are desirable and those in which they are not desirable.

III. Congestion.

Spinal congestion, or plethora spinalis, is not less definite in its history than myelitis or spinal meningitis, neither is it of less practical interest. In the sequel, indeed, it may appear, not only that spinal congestion is fully entitled to the place which has been assigned to it in the catalogue of diseases, but also that it really comprehends more than one spinal disorder which is now known under a different name.

1. Symptoms.—As an instance of well-marked spinal congestion, I take in a condensed form the notes of a case under my care not long ago.

Case.—Mary L., aged 28, but looking very much older, married but never pregnant, was admitted into the Westminster Hospital on the 12th of June, 1866.

(a) With the exception of being able to turn her head on the pillow and to move the fingers and toes a little, all power of voluntary movement appears to be wanting. The symptoms chiefly complained of are tingling in the tips of the fingers and toes, a dull burning aching along the back and in the limbs, and a feeling of being “tired to death.” If altered in anywise, the sensibility to touch, pain, tickling, and differences of temperature, is somewhat more acute than natural. The spine is nowhere tender on pressure, but the dull burning aching in this region is increased by the application of a sponge soaked in hot water. The soles of the feet may be tickled without giving rise to undue reflex movements. The bladder and bowels act properly. The mind is not at all affected. The state generally is evidently one of great exhaustion and prostration without fever, the pulse being quick, unsteady, and very compressible, the respiration shallow, and curiously interrupted by sighs.

(b) Three weeks ago, menstruation, which had only just begun, was suddenly checked by an alarm of fire. This was shortly before bed
time. The next morning, after a very sleepless and miserable night, the state had become very much what it now is. Up to this time the patient had never been obliged to remain in bed a single day on account of illness. She had often been weak and ailing, and she had suffered a good deal at the menstrual periods from pain and weakness in the back and legs, and that is all. She also appears to have sprung from a tolerably healthy stock.

(c) Within the first fortnight after admission to the hospital, the tingling in the tips of the fingers and toes came to an end, and so did the aching in the back and limbs. A week later the arms as well as the hands could be moved a little. At the end of six weeks the legs remained almost as helpless as at first, but the arms and trunk had so far recovered power as to allow of a change from the lying to the sitting posture without any great difficulty. At the end of twelve weeks it was possible to get out of bed, and, with the help of a stick, to move to the table in the centre of the ward. On the 3d of December, five months after admission, the patient left the hospital convalescent. All this while the appetite was tolerably good, and the bladder and bowels acted properly. Now and then, in the progress towards recovery, especially about the menstrual periods, there were short relapses in which the tingling in the tips of the fingers and toes, and the aching in the back and limbs, came back, and the paralytic weakness of the muscles was almost as great as at first—in which the ground already gained seemed all but lost. Now and then, also, the nights were disturbed by a distressing state of shortness of breath, not amounting to asthma. Before the legs recovered power their muscles were somewhat wasted, but not considerably so; indeed, neither here nor elsewhere was the paralysis accompanied by any marked wasting of the muscles or by any appreciable impairment of electro-sensibility or electro-contractility. Moreover, any movement, whether active or passive, had always the effect of relieving rather than of increasing the aching in the back and limbs, when this symptom was present. The treatment pursued was chiefly rest, good living, hypophosphite of soda, nux vomica now and then in small doses, cod-liver oil, and faradisation.

Assuming, as I well may, this to be a case of well-marked spinal congestion, I take as points of comparison between it and other cases of the kind, general and partial, these:—suddenness of access; incomplete paralysis in a paraplegic form; no numbness; tingling in the tips of the fingers and toes; no exaggeration of reflex excitability in the paralysed limbs; no want of control over the bladder and bowel; no spinal tenderness; aching in the back increased by warmth; pains in the back and limbs not increased by movement; no marked impairment of the electro-contractility and electro-sensibility, and no material wasting, of the paralysed muscles; no feverishness; breathlessness; no bed-sores; proneness to relapses.

Suddenness of onset.—To be well, or comparatively well, on going to bed, and to be paralysed in the morning, as in the case which I have given, is no uncommon thing in spinal congestion. It is indeed
the rule rather than the exception for the illness to be spoken of as a “stroke” by the sufferer.

Incomplete paralysis in a paraplegic form.—Paralysis, often all but complete, but never quite so, and taking the paraplegic form, must be looked upon as a common symptom in spinal congestion. The paralysis is decidedly paraplegic in the end, and it may be so from the beginning, but not unfrequently one leg or one arm is affected before the other, and occasionally the leg and arm of the same side may for a short time be affected, as in hemiplegia, before the disease extends to the leg and arm of the other side. Not unfrequently there remains a difference in the degree of paralysis on the two sides, one leg or arm being more affected than its fellow. In cases where the congestion of the cord is general the arms as well as the legs are affected, the former perhaps as much as the latter; but in the common run of cases, where the congestion is confined chiefly to the lumbar region of the spine, the legs are exclusively or chiefly affected.

No anaesthesia.—Numbness is a symptom of myelitis, but not of spinal congestion. In the latter disorder, indeed, instead of numbness there is occasionally a state of things which may be spoken of as hyperaesthesia: thus, in a case very like the one I have given, which came under my notice in private practice about three years ago, the weight of a single bed-sheet was distressingly heavy to the patient, and long-continued aching of the paralysed arms and legs was produced by handling them ever so lightly.

Tingling in the tips of the fingers or toes of the paralysed limbs.—This symptom is almost always present at one time or other, coming and going and staying a longer or shorter time, often, as it would seem, very capriciously. One is glad to get rid of it, for while it remains it is difficult altogether to put aside the fear lest the state of the cord should pass out of spinal congestion simple into the graver disease of myelitis.

No exaggeration of reflex excitability in the paralysed limbs.—Increased disposition to reflex movement is usually regarded as one of the symptoms in spinal congestion. It is supposed that the greater afflux of blood to the spinal cord must bring with it greater reflex excitability. I believe, however, that this supposition is not at all borne out by the facts. I believe, indeed, that the moderate reflex excitability in the case under consideration is not at all exceptional, and that it is the rule in all cases of spinal congestion for this manifestation of muscular contractility to be, if altered at all, diminished rather than increased.

No paralysis of the bladder or sphincter ani.—In myelitis, paralysis of the bladder or sphincter ani, more or less complete, is a prominent symptom: in spinal congestion, on the contrary, these symptoms are absent, except in those mixed cases where there is reason to believe that some degree of myelitis is also present. In the case which I have given there was not the least want of control over the bladder or bowel from the beginning to the end.

No tenderness on pressure along the spine.—Absence of spinal tender-
ness I believe to be the invariable rule, not only in spinal congestion, but also in myelitis and spinal meningitis. I believe, indeed, that spinal tenderness is a sign of the presence of that functional disorder of the cord which is usually called spinal irritation, and that it does not accompany the graver diseases of the cord which have been named when they are uncomplicated with spinal irritation. Upon this subject I shall have more to say presently.

*Dull aching along the spine increased by warmth.*—I have noticed this symptom in three cases of well-marked general spinal congestion which have come under my own observation, and in many cases of partial congestion; and I am disposed to think that this will prove to be one of the points of difference between spinal congestion and spinal irritation. I have also noticed the same symptom in myelitis and spinal meningitis, and therefore I cannot regard it as having any special connexion with spinal congestion. In fact, so far as my experience goes, I can say that this symptom is likely to be met with in congestive or inflammatory diseases of the cord, but not in spinal irritation simply; and that in this latter case, the local application of warmth to the spine is more likely to relieve pain than to cause it.

*Pains in the back and limbs not increased by movement.*—This symptom has some claim to be regarded as constant. The aching would seem to go and come with the congestion; and the fact, for fact it seems to be, that it is not increased by movement, may help to distinguish spinal congestion from spinal meningitis, for in the latter affection movement of the limbs, whether passive or active, is attended with pain in the parts moved and in the back.

*No marked impairment of electro-contractility and electro-sensibility in, and no wasting of, the paralysed muscles.*—In myelitis the paralysed muscles are prone to waste and to lose their electro-contractility and electro-sensibility, and herein, therefore, would seem to be a marked difference between this disorder and spinal congestion; for, so far as I know, the contrary state of things invariably holds good in spinal congestion. In speaking thus, however, it must not be forgotten that all muscles which remain paralysed eventually lose their irritability and struction; and this equally, whether the paralysing cause be myelitis, spinal congestion, or other.

*No feverishness.*—This is no special feature; indeed, fever would seem to have little to do with any affection of the cord, not even excepting meningitis in its most active form.

*No bed-sores.*—A marked disposition to bed-sores would seem to be the rule in myelitis, but not so in spinal congestion or spinal meningitis. Upon this point, more than upon many others, there is tolerable unanimity of opinion.

*Shortness of breath.*—Where the spinal congestion is at all general, this state of things may be readily accounted for by the paralytic weakness of muscles concerned in respiration. In the case which serves as my text, the occasional shortness of breath is noticed as not
amounting to asthma; and this is a point of some interest, for it may be supposed that the difficulty of breathing would have taken this form—would have had something of a decidedly spasmodic character—if the congested condition of the cord involved, as it is supposed to do, an exaggeration of reflex excitability.

Proneness to relapse.—Whether this may prove to be a constant feature in spinal congestion remains to be seen. That it is not an uncommon one is to me an indisputable fact.

Spinal congestion varies greatly in its degree and in the extent of cord implicated. Limited to the lumbar region, and carried to a degree which produces, not paralysis, but weakness more or less approaching to paralysis in the legs, it is common enough; indeed, many women seem to suffer from it before every menstrual period; and between this partial and incomplete form and the general and complete form, of which the case which has been given is an instance, there are all possible grades of transition. It would seem to be most common in women, but it is not peculiar to the female sex or to any age. The onset of the disorder is generally sudden, in relapses as well as in original attacks; and the cases do not at all divide themselves into acute and chronic as do the cases of many other disorders.

2. Post-mortem appearances.—These appearances are very vague and unsatisfactory, at most being simply some engorgement of the veins of the spinal cord and membranes, with some excess of the spinal fluid, both of which phenomena, as will be easily understood, are not very unlikely to escape detection unless the post-mortem examination be conducted with unusual care. With the exception of this engorgement and serous effusion, the only morbid sign which has been noticed (and this by no means constantly) is slight infiltration with blood of the cellular tissue exterior to the dura mater. In all uncomplicated cases, the structure of the cord and of its membranes is in nowise altered.

3. Causes.—As in the case which I have given, the suppression of the catamenia would seem to figure most conspicuously among the causes of spinal congestion, and next to this the cessation of hemorrhage from piles. Beyond this it is difficult to single out any one cause which has a just claim to be considered as at all special: and, for the rest, nothing further need be said except this,—that spinal congestion is not unfrequently a consequence of pulmonary or abdominal congestion or inflammation—a consequence, perhaps, which has often more to do in compromising the safety of the patient than the primary disorder itself.

4. Diagnosis.—Paraplegic paralysis is a symptom common to spinal congestion and myelitis, with this difference, that it is less complete in the former affection than in the latter. The paralysis is associated with anaesthesia in myelitis; not so in spinal congestion. The control
of the bladder and bowels is lost in myelitis; not so in spinal congestion. The paralysed muscles are prone to waste and lose their electro-contractility and electro-sensibility in myelitis; not so in spinal congestion. The imperfect paralysis and the absence of anaesthesia would seem, indeed, to connect spinal congestion more closely with spinal meningitis than with myelitis, and so also would the pain in the back and aching in the limbs; but the pain and aching in spinal congestion cannot well be confounded with the pain which is met with in spinal meningitis, for the pain in this latter affection is produced by movement and accompanied by rigidity, whereas the pain in the former affection is not produced and accompanied in this manner. Hysterical paralysis, so called, agrees with the paralysis depending upon spinal congestion in some respects, but not in others. It agrees in that the paralysed muscles are neither prone to waste nor to lose their electro-contractility; it disagrees in that numbness is a prominent symptom, more prominent even than the paralysis, and that the electro-sensibility of the paralysed muscles is either annihilated or very much diminished.

5. PROGNOSIS.—Recovery is the rule, no doubt, in cases of spinal congestion, but there is no difficulty in finding cases in which the disease has been fatal, and quickly fatal too. In the partial form, affecting the lumbar portion of the cord only, spinal congestion may come and go quickly without any great damage being done; but in the cases in which the cord is more extensively and more profoundly affected, as in the case which has been cited, recovery may occupy a considerable time. Thus, of the cases recorded by Ollivier, No. 55 remained in hospital nearly five months, No. 56 two months, No. 57 three months, and No. 58, "assez longtemps." Recovery is slow, as it would seem, because time is required for the absorption of the excess of spinal fluid to which the state of spinal engorgement had given rise.

6. TREATMENT.—What has been said respecting myelitis must be supposed to apply here equally. Indeed, the only special remark which appears to be called for in this place is this,—that in cases where, as very generally happens, the spinal congestion can be referred to suppression of a menstrual or haemorrhoidal discharge, the primary indication would appear to be the setting up of an equivalent discharge by applying leeches to the os uteri or to the anus.

IV. TETANUS.

Tetanus is unhappily no rare or unfamiliar malady. The name, from τελέω, I stretch, refers to that rigid and cramped condition of the muscles which is the most characteristic symptom, and which, in sober earnest, is suggestive of rigor mortis, not only in posse but actually in esse; for there are some cases in which, without
any interval of relaxation, tetanic rigidity at once passes into cadaveric rigidity. Hydrophobia alone excepted, tetanus is at once the most appalling and the most perilous of all spasmodic diseases.

1. Symptoms.—As an instance of well-marked tetanus, I take the notes of a case which I happened to see from the beginning to the end about six years ago.

Case.—Patrick M——, a fair, slightly-built, delicate-looking man, unmarried, aged 27, the coachman of a gentleman then under my care. On the 21st of April, 1861, as I was leaving the house of his master, I found him in the hall, and he took the opportunity of saying that he was not well enough to bring round the carriage, and of asking me what he had better do. What he complained of chiefly were a stiff neck and sore throat, with a feeling of weakness and illness. The stiff neck and sore throat made their appearance for the first time this day; the feeling of illness and weakness have been present for the last three days. The mouth cannot be opened so as to allow a fair look at the tongue, and a meal, it appears, has just been left unfinished, not for want of appetite, but simply on account of the difficulty experienced in masticating and swallowing the morsels. There is no feverishness.

P. M—— ascribes his present indisposition to having been out with the carriage several hours in the wet and wind three nights ago, and he says further that he is liable to colds. Before speaking to me, he had taken some opening medicine which a chemist had prescribed and prepared for him, and he thinks that this dose may account for the fact of feeling so ill and weak at the present moment. Some simple treatment was recommended, and I took my leave, not at all divining what was so soon to follow.

April 22.—Receiving information that this poor fellow was not so well, I went round to see him at his lodgings. I found him strangely altered. His teeth were firmly and inseparably clenched, and he looked literally like an old man—so like, that his mother, who lived with him, said that she could have thought his father had come back to life if only his hair had been grey. His voice has also become so low and indistinct as to make it difficult to catch what he said. The medicine given by the chemist yesterday, it appears, has purged him violently several times in the night, and more than once while at stool he has been seized with acute pain in the pit of the stomach, which took away his breath, and made him think he was going to die. It was in the night, while at stool, that the jaws became closed. I wished him to go to the hospital, and he was willing to do so, but his mother would not consent. Eggs beaten up with brandy were ordered to be given repeatedly, and every three hours a draught containing five grains of quinine and half a drachm of Hoffmann’s anodyne. I now noticed on one of the fingers, which was tied up in a piece of rag, a small wound, healing and apparently healthy, the result of a tear by a rusty nail about a fortnight ago.

DISEASES OF THE SPINAL CORD.
On a second visit, later in the day, I found that repeated attempts had been made in the interval to give the food and medicine, but with very trifling success. There was no great difficulty in getting the food or medicine into the mouth, for almost all the teeth on the right side were gone, but the attempt to swallow brought on spasm in the throat, and on more than one occasion the spasm forced the greater part of what was taken back through the nostrils. And this difficulty was all the more distressing, because a feeling of hunger prompted the patient of his own accord to make frequent attempts to swallow. The chief complaint now was of a dragging pain at the pit of the stomach, piercing through to the back. In answer to a question whether he could sit up in bed, he said, "I think I am too stiff to do so," and then he tried to sit up, and succeeded after making two or three abortive attempts. While sitting up, I found that he could scarcely move his head, and that the muscles of the neck and back were very stiff and hard. I had only just noticed these phenomena when the noise caused by the upsetting of a chair brought on a fit of spasm, in which the patient was suddenly thrown backwards upon the bed with considerable force, and left resting upon his head and heels, in a state of complete opisthotonos—a state so complete as to make it possible for me to pass my hand under the loins without touching either the body or the bed. This severe spasm lasted not less than a couple of minutes, and the only muscles which did not seem to be implicated in it were the abdominal, those of the arms and hands, and those of the eyeball. In this spasm the complexion became dusky and livid, and the features altered in a frightful manner, the angles of the mouth being drawn upwards and outwards so as to give the expression known as the *risus sardonicus*, the set teeth being slightly uncovered, the nostrils spread, the eyes staring and prominent, the brow knitt, the hair bristling,—the complexion and features became changed, that is to say, as they are changed in sudden suffocation. All this while, too, the skin generally was dusky and hot and drenched in perspiration. For some time after this spasm had passed off the patient remained moaning, and unable to speak audibly, and then he said, "That pain will kill me if it comes back." I noticed, also, that there remained after this spasm a state of tetaniform rigidity and contraction, by which no inconsiderable degree of opisthotonos was still kept up. The eggs and brandy and the medicine were ordered to be given by enema.

*April 23.*—Two attempts were made to administer the enemata ordered over night without success, the irritation of the pipe in each instance bringing on a fit of spasm; indeed, all that it has been possible to give since my last visit have been a few sips of wine and water. There has been no sleep whatever during the night. During the last eighteen hours several fits of spasm like the one described have occurred, and the permanent rigidity and contraction remaining between the fits have increased. The abdominal muscles, which were
not at all implicated yesterday, are now as hard and stiff as those of the neck, back, and legs. The pulse is quick (about 140), weak, and somewhat irregular: the breathing is shallow, hurried, and frequently checked by gasps and catches, even when it is not interrupted by the fits of spasm.

No material change has taken place since the morning. On one occasion in the course of the day an egg beaten up with some brandy has been swallowed, but all other attempts to administer food or medicine, whether by the mouth or by the rectum, have been rendered abortive by the fits of spasm to which they gave rise.

April 24.—Again the night has passed without sleep, and to-day the constant tetaniform contraction has become almost universal. In fact, the only muscles which are not obviously affected are those of the hands, and tongue, and eyeball. The fits of spasm, also, are now more frequent and severe, being not more than fifteen or twenty minutes apart, and lasting until death from suffocation seems even more than imminent; they are brought on by the most trivial causes—an attempt to swallow, a draught of air, the simple straightening of the bedclothes—or they come on without any apparent cause. There is no improvement in the breathing and pulse, but if anything a change for the worse. During the fits the skin is hot, dusky, and drenched in perspiration: in the intervals it has an ominous coolness and clamminess. The mouth is full of viscid frothy saliva, and there is much thirst. While I was present a small quantity of dark urine was passed slowly and with some difficulty, and this appears to be the only time the bladder has acted for at least twenty-four hours. The pupils are large, especially in the paroxysms.

Shortly before I went again at the end of the day, there had been a momentary snatch of sleep, which had been abruptly brought to an end by an attack of opisthotonos, in which the tongue or cheek had been bitten, and now the frothy viscid saliva which filled the mouth to overflowing was deeply crimsoned with blood—a ghastly addition to a countenance already overcharged with horrors. During the last six hours the paroxysms have been less frequent and severe, but the vital powers are evidently fast ebbing away. "I cannot get my breath," was the answer slowly and almost inarticulately given to the question, "Have you much pain?"

Death happened about midnight, an hour after I had taken my leave, after a paroxysm of opisthotonos of no special violence, brought on, as it would seem, by an attempt to wipe away the bloody saliva from the lips. When I left the mind was perfectly clear and collected, and at no time, either before or after, was it otherwise.

For the rest it only remains to add (for the objections made to a post-mortem examination were insuperable) that the countenance appears to have retained after death the aged expression it had before death, and that the corpse when "laid out" was found to have stiffened without losing altogether the opisthotonic attitude. The mother of the patient is my only authority upon these points, for
unfortunately it did not occur to me to make inquiries respecting them before the funeral had taken place.

In order to realize the points of resemblance and difference between this case and other cases of the kind, the course I propose to pursue is to take one after the other, as the points demanding attention, these—permanent muscular contraction, beginning by causing trismus, ending by causing opisthotonos, and implicating when at its height almost all the voluntary muscles except those of the hands, the eyeball, and the tongue; pain at the pit of the stomach piercing through to the back; difficulty of swallowing from the occurrence of spasm; fits of painful spasm in the permanently contracted muscles; risus sardonicus, and an aged expression of countenance; apnoea in the fits of spasm, and more or less dyspnœa at other times; profuse perspiration in the fits of spasm, with heat of skin; increased reflex excitability; absence of fever; absence of sleep; absence of numbness or tingling; absence of "head symptoms;" no marked want of control over the bladder and bowels; comparative voicelessness; the mouth clogged with viscid frothy saliva; a bitten tongue or cheek; dilatation of pupils; absence of priapism; presence of a wound; death by apnoea; early if not immediate rigor mortis.

Permanent muscular rigidity, causing, first, trismus, then opisthotonos, and implicating, when at its height, almost all the voluntary muscles except those of the hands, the eyeball, and the tongue.—Muscular rigidity, continuing without any marked relaxation from the time of its first appearance, is the most characteristic symptom of tetanus. It would seem to be the rule for this state of stiffness to begin in the muscles of the jaws, causing trismus, and to extend from thence as a centre, first to the muscles of the face and neck, then to those of the back, causing opisthotonos, then to those of the lower extremities, and, lastly, to those of the upper extremities, the progress in both extremities being from above downwards; but there are exceptions to this rule, for a few cases are on record in which the muscles of the neck have been affected before those of the jaws, and others, also only few in number, where the muscles near a wound, as of a stump after amputation, have been the first to become rigid. Even in the most extreme cases, the hands and the tongue are found to remain limber, and it is but very rarely, except perhaps in children with "head-symptoms" in addition to the ordinary phenomena of tetanus, that a squint or a fixed stare shows that the deep muscles of the orbit are affected. Fits of spasm, of which more will have to be said presently, may seize upon the tongue, as they do very frequently upon the muscles of the throat in attempts to swallow, but there is no proof that either the tongue or the muscles of the throat are ever in a state of permanent contraction. Neither is there any certain proof that the heart or other involuntary muscles are in any degree permanently contracted. The affected muscles are very hard, curiously so, feeling very much as they do in rigor mortis, and they are not unfrequently somewhat tender when pressed or squeezed. In the great majority of
cases, without question, the first effect of tetanic rigidity is to close the jaws and cause trismus, and the next to bend the body backwards and produce opisthotonos. Opisthotonos, indeed, is almost as characteristic and constant a result as trismus. Now and then, it is true, instead of the body being bent backwards it may be bent forwards (emprosthotonos), or sideways (pleurosthotonos), but these cases are quite exceptional, and opisthotonos may in reality be looked upon as the position which the body always takes or tends to take in tetanus.

Pain at the pit of the stomach piercing through to the back.—This is reckoned by the late Dr. Chambers as the pathognomic symptom of tetanus, and in fact it is scarcely ever absent, not even at the very beginning. This pain is especially severe in the fits of spasm, and then it is often agonising, but it is present also, if not in a severe, at least in a mitigated form, in the intervals between these fits, scarcely ever ceasing altogether, even for a moment, when once it has made its appearance. It depends, there is little reason to doubt, upon the diaphragm being implicated in the tetanic condition. Once it was looked upon as a certain death-warrant, but this opinion, as Mr. Curling has shown, is untenable.

Difficulty of swallowing from the occurrence of spasm.—This spasm, which is provoked by the attempt to swallow, may be in the pharynx or gullet, or in the cardiac aperture of the diaphragm, one or all, making swallowing impossible, and often leading to the violent ejection of fluids through the nose or from the mouth. The distress consequent upon it may sometimes cause a horror of liquids not unlike that which exists in hydrophobia, and it always constitutes a grave difficulty, for it not only incapacitates the patient from feeding in the usual way, but it prevents him from being fed by means of the stomach-pump.

Fits of painful spasm in the permanently contracted muscles.—These fits become more frequent as well as more violent and painful as the disease progresses, recurring when at the worst every ten or fifteen minutes, and lasting from one to two and a half minutes. So violent has been the muscular contraction in some of these fits, that the teeth and thigh bones have been broken, and great muscles like the psoas and recti femorales torn across. These fits of spasm are almost invariably very painful, the pain being that of cramp, but now and then the pain has been absent: thus, Sir Gilbert Blane mentions, on the authority of a surgeon in the navy, a case of severe tetanus, fatal in four days, in which the fits of spasm only gave rise to a sort of pleasurable tingling; and Mr. Curling instances an analogous case. Most generally the pain in the fit of spasm is felt chiefly at the pit of the stomach, and very often the pain in this region may be so agonising and stifling as to make the patient insensible to pain elsewhere. Sometimes the pain in the neighbourhood of a wound, as in the stump after amputation, is that which is most complained of.

Ritus sardonicus and an aged expression of countenance.—The
sneering expression, caused by the angles of the mouth being drawn backwards and upwards, and known as the risus sardonicus, in association with spread nostrils, staring and prominent eyes, knitting of the brows, and bristling of the hair, is so often present as to be properly reckoned as pathognomonic of tetanus. In the fits of spasm the lips are often drawn apart so as to expose the set teeth, but sometimes they are kept tightly pressed together by the spasmodic action of the orbicularis oris. The aged expression which was present in the case I have given, is exceptional, but it has been met with in other cases. Thus, Mr. Curling refers to a case of idiopathic tetanus, related by Dr. W. Farr, in which the patient, who was only twenty-six years of age, looked at least sixty; and he says further that he himself has "observed the same circumstance in an equally remarkable degree."

*Dyspnœa with fits of comparative apnœa.*—When tetanus is fully developed, an apprehension of suffocation is often present even in the intervals between the fits of spasm, and in these fits the suffused eyes, the livid countenance, and the agonising struggle for breath show plainly enough that this is in no sense a groundless fear. How this difficulty is brought about is not easy to say, and probably the way is not always the same. Sometimes spasmodic closure of the glottis would seem to be a prominent cause; sometimes the thorax is, as it were, held in a vice by the spasm of all its muscles generally; most commonly perhaps these two causes act together. From my own small experience I should be disposed to attach less importance to the last cause than to the first, and I question whether much relief would be obtained in any case by carrying out Marshall Hall's suggestion of opening the windpipe in cases of tetanus.

*Increased reflex excitability.*—In P. M——, as the disease advanced, the fits of spasm were brought on by the most trivial causes—a draught of air, a sudden noise, an attempt to swallow, an attempt to administer an injection, the arrangement of the bed-clothes, the lightest touch even—and hence it may be inferred that increased reflex excitability was an element in this case. Nor is this case at all exceptional in this respect. As the disease advances, in fact, the controlling influence of the nervous system is removed, and this is all, for what are counted as signs of increased reflex excitability are in reality no more than signs of nervous exhaustion, such as manifest themselves whenever the vital powers are sufficiently lowered by loss of blood, or in any other way.

*Profuse perspiration with heat of skin, in the fits of spasm especially.*—In the fits of spasm the skin becomes hot and literally drenched in perspiration, and in a lesser degree this state of things continues in the intervals between these fits, except towards the end, when the chill damps of death show themselves. Sometimes the perspiration has a peculiar pungent smell, sometimes it is accompanied by a milhary eruption. The degree of heat attained is often considerable—in some cases as high even as 105° and 110°75° Fahr.

*Absence of fever.*—The heat of skin which has just been mentioned
DISEASES OF THE SPINAL CORD.

may at first sight appear to countenance the notion that fever is a part of tetanus, but it is evident on further inquiry that this phenomenon is mostly connected, not with fever, but with dyspnea, the skin receiving more blood, and in that way acquiring increased temperature, in obedience to that law of compensation by which to a certain degree the skin is obliged to do more respiratory work when the lungs do less than they ought to do. The thirst, also, which is often so much complained of when the disease is at its height, is owing less to fever than to the inability to drink the fluids necessary to the wants of the system, for the patient is often hungry at the very time he is tortured with thirst—a plain proof that he has no fever in the true sense of the word. Nor does the pulse support the idea of fever. On the contrary, the pulse points to exhaustion rather than to fever, being scarcely ever otherwise than quick and weak; and if in the fits of spasm it puts on a semblance of power, it is plain, from the state of suffocation obtaining at the time, that this change is simply owing, as I have elsewhere explained, to the difficult passage of imperfectly aerated blood through the capillaries. In fact, in the great majority of cases of tetanus there is no fever, and in the exceptional cases where some fever is present, its history shows that it is a consequence rather than a cause of the spasm, seeing that it is absent at first, and present only when the system is becoming exhausted by starvation, sleeplessness, and spasm.

Absence of sleep.—In the acute cases sleep, as a rule, is banished altogether, and even in the subacute cases this blessing is only realized in unrefreshing broken snatches. Want of sleep, indeed, is one of the not least distressing features of this disease. "The muscles," says Mr. Curling, "are observed to be relaxed during sleep, a striking example of which occurred to Mr. Mayo in a boy who recovered from the disease. On visiting his patient before the symptoms were subdued, Mr. Mayo found him asleep, and remarked that he lay perfectly relaxed. The abdominal muscles were soft and yielding, and had not the least tension. The boy was awakened, and at the instant the full tension of the muscles returned. Not being further disturbed, he fell asleep in a few minutes, when the muscles again became relaxed, and again, on his being awakened, resumed the state of spasm. I have, on several occasions, witnessed the same phenomena." Except the biting of the tongue, on waking from a brief nap, be a reason for believing that the muscles of the jaws had been relaxed during sleep, so as to allow the tongue to get between the teeth, there was no proof that the muscles were relaxed during sleep in the case I have given; but in other cases I have had proof sufficient of this relaxation.

Absence of numbness and tingling.—Of this there can be no doubt—that numbness and tingling form no part of the history of tetanus.

Absence of "head symptoms."—The mind is clear from the beginning to the end of the disease almost invariably, and not unfrequently it is a matter for wonder how well the patient bears up under his atrocious sufferings—a marked difference this between tetanus and hydrophobia. And in the few instances in which delirium or coma has made its
appearance a short time before death, it is not improbable, as more than one writer has observed, that this derangement is often more the result of the remedies employed than of the disease.

No marked want of control over the bladder or bowel.—In tetanus there is, as a rule, none of the difficulty with the bladder which is almost invariably met with in acute spinal meningitis. The bladder may act seldom, but it is not incapable of acting. Constipation is a common but not a constant symptom, and when it is present it may be a question whether, like the “head-symptoms,” it is not as much due to the medicines used as to the disease. Now and then, however, there may be great difficulty in voiding the contents of the bladder and bowels, and in some of these cases the resistance to the introduction of a catheter or enema-pipe has shown that a part of this difficulty is owing to spasm of the compressor urethrae or sphincter ani.

Comparative voicelessness.—This phenomenon is readily accounted for as a result of the spasmodic interference with the action of the chest and of the tight shutting of the jaws. Indeed, it could not well be otherwise in the fully developed disease.

The mouth clogged with viscid frothy saliva.—This is a common if not a constant symptom, though not so marked in degree as in hydrophobia, and there is no difficulty in accounting for it in either case, for the inability to drink and swallow will explain at one and the same time why the saliva is viscid and why it accumulates in the mouth.

A bitten tongue or cheek.—This accident is of rare occurrence, and its rarity may be taken as an incidental proof of sleeplessness as a symptom of tetanus, for it is to be supposed that the opening of the jaws, from the relaxation of their muscles during sleep, would allow the tongue or cheek to get between the teeth—to get into that position in which the spasm which attends the moment of waking would be sure to crush them.

Dilatation of pupil.—This condition was always present in the case which serves as my text, especially in the fits of spasm, and this has been the rule in three cases of tetanus in which I have examined the pupil. Mr. Curling, on the contrary, found the pupil contracted in the majority of his cases.

Absence of priapism.—Mr. Morgan states that priapism occurs occasionally; but this observation is not confirmed by other writers on the subject. I have never seen it, and I am very much disposed to think that the case or cases in which Mr. Morgan saw it were cases, not of tetanus, but of acute spinal meningitis, in which disorder priapism is an occasional symptom.

Presence of a wound.—The great majority of cases of acute tetanus appear to be in some way dependent upon a wound or injury of one kind or another in one place or another. I shall have occasion to refer to this relationship elsewhere: and at present I would only notice, in passing, the presence of a wound which to all appearance presented no indications of an inflammatory or otherwise unhealthy character.
**DISEASES OF THE SPINAL CORD.**

*Death by apnoea.*—Apnoea is one way, and perhaps the common way, in which death is brought about in tetanus. Not unfrequently, however, the patient sinks from asthenia, having been to a great degree free from fits of suffocative spasm for some time before death. Spasm of the heart has also been mentioned as a method of dying in tetanus, and the heart has not unfrequently been found to be curiously hard and contracted after death; but an examination of the facts tends very much to discountenance this idea, and to show that death is either by apnoea or asthenia, singly or together.

*The immediate occurrence of rigor mortis.*—Sommer and others have noticed that rigor mortis may occur without any appreciable interval of muscular relaxation after death from convulsions, and Dr. Brown-Séquard has confirmed this observation and given a definiteness to it which it had not before. He has indeed done more than this, for he has not only confirmed the fact that rigor mortis may occur without any appreciable interval of muscular relaxation, but he has established the law that rigor mortis is long in coming on and long in passing off where death was not preceded by any long-continued violent action of the muscles, and that it is quick in coming on and quick in passing off in direct proportion to the amount of long-continued violent action which preceded death. In many animals killed by strychnine, for example, in which death was brought about, not by one violent spasm, but by many, he has found rigor mortis set up before the heart had ceased to beat. Nay, he even refers to the case of a man under his own observation in which rigor mortis occurred before the heart had ceased to beat. I have never witnessed this phenomenon either in animals or in man; but I have more than once failed to find any line of separation between tetanic stiffness and cadaveric rigidity in animals killed by strychnine, or by the shocks of a Ruhmkorff coil; and I am therefore quite prepared to understand that in P. M.—'s case, where there were many convulsions before death, rigor mortis may have occurred without any appreciable interval of muscular relaxation, and in this way fixed in the corpse the aged expression of the countenance, and the opisthotonic attitude.

Two distinct varieties of tetanus are usually recognised, and properly so,—the *traumatic*, in which a hurt of some kind or other is believed to be the primary cause; and the *idiopathic*, in which the only obvious cause would seem to be exposure to cold and damp. In each variety the symptoms are much the same, any difference of moment being only one of degree. In the acute form, the spasms come on suddenly, occur frequently, and grow in violence with each recurrence; in the less acute forms the spasms are more slowly developed in the first instance, the paroxysms are comparatively far between, and they do not recur with increasing rapidity and violence. The traumatic, as a rule, is more acute than the idiopathic variety. Trismus nascentium is considered by many as a distinct variety of tetanus, but this appears to be a distinction without a real difference. It is tetanus in newly-born infants,—traumatic, because the wound of the navel seems to
have a good deal to do with its production, and at the same time idiopathic, for it is certain that cold and damp, and foul air, and other general causes also figure conspicuously as sources. It is, indeed, to this form of tetanus that a remark of Sir Thomas Watson applies especially, which is applicable to all forms, namely this, that "although tetanus may be excited by a wound, independently from exposure to cold, or by cold, without any bodily injury, there is good reason for thinking that, in many instances, one of these causes alone would fail to produce it, while both together call it forth."

2. Post-mortem Appearances.—There are no morbid changes in the nervous system peculiar to tetanus. "Serous effusion with increased vasculariy," says Mr. Curling, "is generally observed in the membranes investing the medulla spinalis, and also a turgid state of the blood-vessels about the origin of the nerves," and the same changes may also be met with in the cranium, but in a less degree and less frequently. It is also a fact of considerable moment in relation to this point, that Majendie, Ollivier, and Orfila failed to detect any perceptible lesion in the spinal cords of animals dying from the tetanus produced by strychnia. Out of seventy fatal cases collected by Mr. Curling, there were only two in which changes in the nervous system unequivocally the result of inflammatory action were discovered after death, and these two were cases where there had been a blow or wound to the back, where the symptoms had plainly to do with the inflammation of the cord or its membranes rather than with tetanus, and where the signs of inflammation found after death may, to say the least, be referred to the injury quite as easily as to the tetanus. Mr. Curling also points out, as a fact not to be overlooked, that the turgid state of the vessels of the pia mater, together with the effusion of serum which is met with in the spinal cord and brain after death from tetanus, is also met in those persons who have been poisoned by opium, hydrocyanic acid, and other powerful agents often employed in the treatment of tetanus, as well as after death from delirium tremens, hydrophobia, epilepsy, and other diseases; and, as bearing upon these exceptional cases, in which unequivocal signs of inflammation in the cord or brain have been met with after death from tetanus, he says, "Whether inflammation be the result of injury or arises spontaneously, it is worthy of notice that the spasms, though continued and severe, do not occur in such violent paroxysms as in traumatic tetanus." Neither can the preternaturally injected state of the minute vessels supplying the sympathetic ganglia, especially the cervical and semi-lunar, met with by Mr. Swan and others in some cases of tetanus, be looked upon as at all constant phenomena after death from tetanus.

Traces of inflammation in the wound, especially in the injured nerves, may be met with after death from tetanus, and more frequently than in the spinal cord or other great nervous centres; but these again, instead of being constant, are not even common appearances. In the great majority of cases, indeed, the wound, if there be one, is
perfectly healthy to all appearance and healing. Neither are there any other post-mortem facts which can be looked upon as essential to tetanus, for those which remain to be mentioned, as ruptured muscles, broken or dislocated bones, engorged lungs, injection and contraction of the pharynx and palate, worms in the alimentary canal, and others, are plainly accidental and exceptional.

3. Causes.—The two great causes of tetanus are, as has been mentioned already, cold and damp, and bodily injury of some sort. Exposure to cold and damp tells most in this manner when acting upon a body previously relaxed by heat and perspiring, and this is all that can be said, except that this exposure is more likely to issue in tetanus in a foul atmosphere than in a fresh one. As regards the hurt which may give rise to tetanus, it is difficult to know what to say. In the Peninsular war, as Sir James McGregor states, tetanus supervened on every description and in every stage of the wounds, from the slightest to the most formidable, in the healthy and sloughing, the incised and lacerated, the most simple and the most complicated; and this statement expresses the opinion of all surgeons, army-surgeons and others. Indeed, all that can be said is that punctured wounds seem to be more likely to issue in tetanus than incised, and wounds in the extremities more than wounds in the head, breast, and neck. And certainly an inflammatory condition of the wound cannot be regarded as essential. In a great number of cases, in the majority perhaps, the primary wound was completely healed and almost forgotten when the symptoms of tetanus made their appearance; and Dr. Rush, who had extensive opportunities for observation in the military hospitals of the United States, and who was unquestionably a most competent observer, remarks that there was invariably an absence of inflammation in the wounds causing the disease. John Hunter also says: "The wounds producing tetanus are either considerable or slight. . . . When I have seen it from the first, it was after the inflammatory stage, and when good suppuration was come on; in some cases when it had nearly healed, and the patient was considered healthy. Some have had locked jaw after the healing was completed. In such I have supposed the inflammation to be the predisposing cause, rendering the nervous system irritable as soon as it was removed. When tetanus comes on in horses, as after docking, it is after the wound has suppurated and begun to heal." There is, indeed, abundant evidence to show that an inflammatory condition of the wound is not necessary to the production of tetanus, and some evidence even which is calculated to lead to a contrary conclusion, by showing that where an inflammatory condition of the wound has been present, this condition has passed off before the tetanic symptoms made their appearance—the inflammation, to repeat the words of John Hunter just used, "rendering the nervous system irritable as soon as it was removed," not rendering it irritable as long as it was present. The interval between the hurt and the development of the
tetanic symptoms varies considerably. In eighty-one of the cases collected by Mr. Curling, the symptoms made their appearance between the fourth and fourteenth days, both inclusive, and in nineteen on the tenth day. Four cases are also given in which the symptoms came on more speedily, one (somewhat doubtful) almost instantaneously, another in one hour, a third in two hours, and the fourth in eleven hours, and, at the other extreme, one in which they were deferred as late as the tenth week. In traumatic tetanus the sooner the symptoms show themselves the more acute and dangerous is the malady. In idiopathic tetanus the symptoms, as a rule, commence sooner than in traumatic tetanus, often in a few hours; but the idiopathic, notwithstanding, is generally of a more chronic kind than the traumatic, and far less dangerous.

Tetanus is not a malady peculiar to any country, or climate, or people, but it is more common in hot countries than in cold. It would appear, also, that negroes are more likely to be attacked than whites. Great atmospheric changes, especially from heat to cold and damp, as to a cold and dewy night after a sultry day, are evidently most favourable to the development of tetanus, and so in a less degree are foul air, despondency, terror, physical exhaustion. It must be confessed, however, that cases of idiopathic tetanus, as compared with those which are traumatic, or partly idiopathic and partly traumatic, are, to say the least, extremely rare in this country.

4. Diagnosis.—The differences between tetanus and acute spinal meningitis are sufficiently marked to prevent any confusion as to diagnosis if only a moderate degree of attention be paid to the subject. In tetanus the jaw is firmly set from the first, and, in addition to the fits of spasm, there is permanent muscular rigidity between the fits: in spinal meningitis, if the jaw be set at all, it is rather at the close of the disease, and then only in an inconsiderable degree, and spasms or muscular rigidity are neither constant nor conspicuous phenomena. In spinal meningitis, indeed, it is plain that the muscular rigidity and seeming spasms are in great measure voluntary or semi-voluntary acts to prevent the pain in the back and limbs which is produced by movement, and that the muscles are relaxed almost as long as the patient can keep perfectly still. In a word, the true involuntary fits of spasm and the permanent muscular rigidity which are constant and characteristic phenomena in tetanus, are not present in acute spinal meningitis.

Nor can hydrophobia be very well confounded with tetanus. In tetanus the features are drawn into the risus sardonicus, the eyes are natural, and the whole countenance is expressive of pain and suffering,—nothing more: in hydrophobia there is an impress of excitement and distress and horror and unrest upon the features which has no counterpart in the tetanic countenance. In tetanus the body is for the most part rigidly fixed in one position by tonic spasm; in hydrophobia the spasmodic movements are clonic, and the body is in a state of per-
petual unrest until the stage of final exhaustion. In hydrophobia, noisy attempts are continually made to spit and hawk away the viscid phlegm which fills the mouth and throat to overflowing—the noises being sometimes not altogether unlike the bark of a dog—and any effort to relieve the tormenting thirst, or even the bare thought of such an effort, brings on the fit of fear and convulsive agitation which has given rise to the name hydrophobia: in tetanus there are no symptoms which can be considered as strictly comparable to these. In tetanus, finally, the mind is clear to the last, whereas in hydrophobia there is almost from the first a peculiar and often very wild delirium.

The tetanic symptoms produced by strychnia and some other poisons may be more easily confounded with traumatic tetanus, but even here it is possible, with care, to make a correct diagnosis. It is possible, as Dr. Christison pointed out, for strychnia to be given in repeated doses so regulated as to produce a train of symptoms scarcely if at all distinguishable from traumatic tetanus; but not so if, as is usually the case, an amount sufficient to produce death be given in one dose. In this latter case, indeed, the differences of the symptoms are sufficiently marked. In the toxic tetanus the symptoms run a rapidly fatal course, death happening in a quarter of an hour, half an hour, and usually within the hour: in traumatic tetanus, with very few exceptions, life when briefest is prolonged for two or three days. In the toxic tetanus the arms are stretched stiffly out, the hands clenched, and the legs separated widely from each other and rigidly extended: in traumatic tetanus the hands are usually free from spasm, and the arms nearly so, and even the legs are scarcely ever affected to the degree which is seen in toxic tetanus. In the tetanus caused by strychnia, Mr. Poland says, "The patient can open his mouth to swallow; there is no locked jaw:" in traumatic tetanus, locked jaw is the first and most constant manifestation of the spasm.

The jaw may be locked for a long time, and various muscles in other parts may be affected with continuous spasm in cases in which hysteria is supposed to figure largely as a cause—cases in which there is the condition called spinal irritation, about which I have to treat in the next article: but these cases, as will appear in due time, even when most like, are in reality so unlike tetanus as scarcely to deserve even this passing mention.

5. Prognosis.—In the cases "in which the access is slow, the spasms by no means violent, the paroxysms slight and recurring at long intervals, and where the patient can obtain sleep, whether traumatic or not, we may generally anticipate a favourable result;" and again, "the longer the interval before the appearance of the symptoms, the more chronic is the disease, and the greater the probability of recovery." So speaks Mr. Curling of the chronic cases of tetanus in contradistinction to the acute; and in illustration of the probability of recovery, he adds: "In thirteen cases, symptoms of tetanus occurred about three weeks after the wound, and four only were fatal; and of seven cases
in which they did not make their appearance till after a month, only two ended fatally." In the cases, on the other hand, in which the spasms supervene rapidly upon the injury, and recur with increasing violence at decreasing intervals, and in which sleep is banished, a vast majority die—die, as Hippocrates noticed ages ago, within four days. Death may happen in a fit of suffocation in which sometimes there is obviously spasm of the glottis, but more frequently it would seem to be brought about by asthenia after a fit of spasm. The time occupied in recovery varies greatly,—one, two, three, four, five, six, seven, eight weeks, or even longer. A certain degree of weakness and stiffness may also remain in the muscles long after recovery. In one case rigidity of the muscles of the jaw remained for six months; in another it returned whenever the patient caught cold up to nine months; and in a third, at the end of three years, it is stated that the "features retained the indelible impression of the disease." These cases are given by Mr. Curling.

6. Treatment.—After passing in review the principal remedies that have been tried in tetanus—opium, blood-letting, the cold bath and cold affusion, ice to the spine, the warm bath, bark, wine and spirits, mercury, purgatives, foxglove, tobacco, musk, prussic acid, carbonate of iron, oil of turpentine, strychnia, wooral, ether and chloroform inhalations, amputation, division of nerves, tourniquets—Sir Thomas Watson says: "In all cases, there being no special indication to the contrary, I should be more disposed to administer wine in large quantities, and nutriment, than any particular drug;" and this statement, I take it, expresses a very general feeling in this country. For my own part, I should certainly be more disposed to trust to alcohol than to any drug; but, in saying this, I do not say that I should place no confidence in drugs. I should certainly place no confidence in any sedative or narcotic given by the stomach in sedative or narcotic doses; but, on empirical as well as on theoretical grounds, I should say that opium can scarcely be dispensed with, and that chloroform or ether inhalations will be of infinite service in relieving pain and spasm, and that too without compromising the chances of recovery, if care be taken to pour in wine and to supply nourishment at the same time so as to prevent the patient from waking up almost immediately after the inhalation.

If the rationale of spasm be that which is hinted at in the preliminary remarks, the great indication of treatment must be, not to depress the circulation, but to rouse it into greater activity; and one reason why the treatment of tetanus has been so eminently unsatisfactory may be that this indication has not been fully realized and carried out. In tetanus much wine may be given without producing anything like intoxication, or without relaxing the spasms in any degree. The system in this disease is altogether insensible to the action of wine in ordinary doses. As to this there can be no doubt. Whether a different result would have been arrived at
if alcohol had been given more boldly, ardent spirits in place of wine, ardent spirits undiluted rather than diluted, is yet an open question, but I am disposed to think that the spasms might have been conquered without compromising the safety of the patient if this had been done. There are now not a few cases on record which show that the bite of a rattlesnake or cobra or other deadly serpent may be prevented from killing by at once giving ardent spirits in sufficient quantity, and I am disposed to think that these facts have an important bearing upon the treatment of tetanus. There are, undoubtedly, great differences between the condition in tetanus and the condition in these poisoned bites, but there are also certain resemblances which must not be lost sight of. There is the same insensibility to the action of alcohol in ordinary doses; there is an exhaustion to be counteracted, which is more rapidly fatal in the poisoned bite than in tetanus, but which in acute tetanus is sufficiently rapid to create the gravest fears, and to justify the most heroic measures; there may even be a poison at work in both cases as well as a wound, a poison introduced into the wound in one case, a poison generated in the wound in the other case. There are resemblances between the two cases, indeed, which, though not very close, may be close enough to justify the hope that a practice which has been found to answer in the bite of a poisonous serpent may also be found to answer in acute tetanus.

In speaking thus, it is not intended to imply that ardent spirits are the only way of fulfilling what has been said to be the primary indication of treatment in tetanus. Eau de luce has been found to be of great service in the bites of serpents, and it might be of service in tetanus. Ether, also, might be of use, or turpentine, or camphor, or ammonia. But to my mind these and other medicines of a like nature are more likely to disorder the stomach and system generally, and in other respects are less manageable and less certain in their action than ardent spirits, and for these reasons without any just claims to precedence in order of merit.

As regards local measures it is less difficult to arrive at a conclusion. In many cases, no doubt, there is an eccentric irritation, starting from the wound or some other point, and much good would be done if this could be removed. It is probable, also, that this end might be gained in more ways than one, and that one very direct way is by the subcutaneous injection of various substances—morphia, atropine, wooral, conia (which seems to be strictly analogous in its action to wooral), calabar bean, &c. The results of these injections in causing the relaxation of spasm in connexion with the minor forms of spinal irritation are very encouraging. One thing, however, ought to be borne in mind, and that is, that these injections should be used so as not to produce a general depressing or paralysing effect upon the nervous system. All that ought to be aimed at is to obviate local irritation merely; and, to my mind, to go beyond this point is both wrong in principle and dangerous in practice.
V. Irritation.

The first important work on the disorder now generally known as spinal irritation was published by Mr. Teale, of Leeds, nearly forty years ago;* the next by the brothers Dr. and Mr. Griffin, of Limerick, about fifteen years later.† To Mr. Teale, indeed, belongs the credit of being the first to direct attention to this disorder, for, in reality, his claim either to priority or originality is scarcely, if at all, invalidated by the short communications which were made previously to medical periodical literature by Mr. Player, of Malmesbury,‡ by Dr. Brown, of Glasgow,§ by Dr. Darwell, of Birmingham,|| and still less so by anything written about the commencement of the century by Franks, Nicod, Ludwig, and others. It would also seem to be difficult to find any work of more recent date which deserves to be mentioned as at all equal in merit and importance to that of the brothers Griffin. The name "spinal irritation" was first proposed by Dr. Brown, of Glasgow.

1. Symptoms.—The symptoms of spinal irritation at first sight appears to be as vague and various as those of hysteria. They are in reality so far hysterical as to be not readily distinguishable. When further examined, however, one symptom stands out prominently, with which the others are obviously connected in a peculiar manner; namely, spinal tenderness, and the upshot of the whole matter appears to be that spinal irritation is a definite malady which must not be confounded with hysteria or with any other disorder. The case I take as a text is as follows:—

Case.—An unmarried lady, aged twenty-three, who consulted me in the early part of 1863 for pains in the head and face, loss of appetite, nausea, flatulence, palpitation, breathlessness, "sinking feelings," weakness, and low spirits. The pain, which was the chief suffering complained of, was sharp and neuralgic in its character, and varying in its seat, being sometimes in one part of the head or face, sometimes in another, and generally on the left side only. In the head it was often limited to a spot which might be covered with the tip of the finger,

DISEASES OF THE SPINAL CORD.

as in true clavus hystericus. Headache in one form or another was
brought on or exaggerated by any effort, physical or mental: it was
usually relieved by lying down and keeping perfectly still; it was
scarcely ever absent except when face-ache had its turn; and sometimes
it was so continuous and oppressive as to necessitate remaining in bed
for days together. Nausea and sickness were its frequent accompani-
ment, and vomiting and great prostration were its common termina-
tion. In the cervical region of the spine there were considerable
tenderness and a disagreeable feeling of weight, and pressure there
brought on or increased the headache—the pain shooting from the
occiput forwards—and caused a feeling of great nausea and oppression
at the precordia. The feet were always cold; "chills and flushes"
were of frequent occurrence, and so were yawning, sighing, and
stretching of the arms. Sleep was often made hideous by nightmare;
fits of lowness of spirits and crying, attended by a sense of choking,
as from a ball or knot in the throat, and followed by plentiful gushes
of pale, limpid urine, were brought on by the most trivial causes; and
the manner and appearance were altogether those of an eminently
nervous or hysterical person. Menstruation was regular, neither
excessive nor deficient, and it could not be said that the sufferings
were either more or less at this time. The bowels also acted properly,
and (but for the disposition to pass large quantities of pale urine,
which has been already mentioned) so did the kidneys and bladder.

These symptoms, it appears, had their starting-point about twelve
years ago in the shock and grief caused by witnessing the death of
a brother, her last remaining near relative, in an epileptic fit, and ever
since this time they have continued very much as they now are, with
but little intermission. Before this time the personal history of the
patient was tolerably good, but not so her family history; for, in addi-
tion to the brother whose death in epilepsy has just been mentioned,
it appears that her father died years before of phthisis, and that her
mother is now in a lunatic asylum.

Under the use of a more liberal diet, with ammonia and calumba,
and with occasional blisters to the nape of the neck, health was re-
established in little more than a month, notwithstanding the fact that
several days at the commencement were wasted in overcoming a dis-
like to take the wine and medicine necessary—in converting, in fact,
the patient from a firm belief in teetotalism and homœopathy.

Towards the close of the same year, 1863, this young lady again
returned to me, looking very worn and thin, with all her old symptoms
in force, and with cough and difficulty of breathing in addition. The
cough was very violent, barking, unattended with expectoration, and
often carried on until it ended in retching and vomiting. The
difficulty of breathing was chiefly at night: usually it did not amount
to more than what might be met by a voluntary effort at inspiration;
now and then it seemed to deserve the name of asthma; almost in-
variably it was accompanied, not by a feeling of a ball or knot in the
throat, but by a sharp pain in the left hypochondrium, or else by

vol. ii. t t
severe aching in the left shoulder and down the left arm. Percussion and auscultation failed to bring to light any signs of disease in the heart or lungs, but pressure along the spine revealed tenderness in the cervical and upper dorsal regions, in the latter especially, and at the same time brought on cough, deep inspirations, pain and throbbing at the epigastrium, and a feeling of great faintness and breathlessness.

On this occasion a very fair state of health was soon re-established by the plan of treatment which proved successful in the first instance.

At the beginning of 1865, this lady, then married, again required my services. For the three weeks before my seeing her she had been in bed, with her thighs drawn up tightly against her abdomen, and with her heels buried in her nates. This contraction was unremitting during the waking state, and only partially remitting during sleep: it was unattended by pain; and it could be partially overcome, for a time, without causing much pain in the contracted muscles, by slow and steady extension. The headache and face-ache had gone months before, and so had the pain in the epigastrium and in the left shoulder and arm: the cough and difficulty of breathing and palpitation were of very unfrequent occurrence; the appetite and digestion and the action of the bowels were tolerably natural; and what was complained of now were colicky pains in the lower part of the abdomen, pains often very severe and sickening about the loins and hips, and in the region of the left ovary, with constant calls to pass water, and much pain in the urethra in attending to these calls. The spine was now tender, not as before in the cervical and dorsal region, but low down in the lumbar region, and pressure on the tender part brought on colicky pains in the lower part of the abdomen, and a cutting pain in the urethra, with an almost irresistible impulse to pass water then and there. Pressure in the cervical and dorsal regions of the spine gave rise, not to the marked symptoms produced in this way in the two previous illnesses, but simply to a disagreeable thrill all over the body. There was no numbness or tingling in the legs or elsewhere, and no hyperesthesia, except perhaps to a very trifling degree over the left ovary. Tickling the soles of the feet gave rise to painful spasmodic shocks in the legs, to a disagreeable thrill passing up the body as high as the throat, and to the involuntary escape of a small quantity of urine. The condition as to general health was tolerably good—much better than during the two previous illnesses; and, in fact, the only sign of disorder, in addition to those which have been indicated (and this can scarcely be reckoned as such), was the absence of menstruation since the birth of a child about three months ago.

Somewhat more than twelve months ago, after having been quite well for the year previously, this patient married and became pregnant. In the early months of pregnancy she had much headache, depression, weakness, and sickness; but after a while these symptoms passed off, and everything went on smoothly and satisfactorily until two months after confinement, when her baby died suddenly. And then
began her present troubles. The fretting about her baby brought back the old headaches, the headaches produced great sleeplessness and irritability of the stomach, and then came on a state of uncontrollable fidgetiness which kept her incessantly moving about until her legs, one leg especially, failed altogether, and obliged her to take to her bed. The very next morning her legs had become contracted, and she herself is convinced that this change for the worse, as she regards it, was brought about by the pain and loss of blood produced by introducing a large speculum and by applying leeches to the os uteri on the previous evening.

The treatment on this occasion consisted chiefly in a liberal allowance of food and wine, in repeated blisters to the lumbar region of the spine, and in the administration of bromide of potassium and ammonia; the result was the cessation of the contractions in about three weeks, and the complete re-establishment of health in about two months and a half.

In commenting upon this case with the view of separating the general phenomena of spinal irritation from the particular, I take the following as the points which most deserve to be attended to, namely these:—spinal tenderness, neuralgia, spasmodic cough and difficulty of breathing, palpitation and vascular throbbings, nausea, vomiting and eructations, and irritability of the bladder, all in connexion with spinal tenderness; the connexion of particular symptoms or groups of symptoms with tenderness in particular parts of the spine; prolonged muscular contraction; no paralysis of the limbs; no paralysis of the bladder or rectum; no numbness; variability and inconstancy of the symptoms; a nervous constitution.

**Spinal tenderness.**—In the great majority of cases this symptom would seem to be present in spinal irritation and absent in spinal meningitis, myelitis, or spinal congestion, acute or chronic. It would seem, indeed, to deserve to be regarded as the pathognomonic symptom of spinal irritation; for in the few cases of spinal meningitis, myelitis, or spinal congestion in which it is met with, there is reason to believe that its presence may be accounted for by the association of the phenomena of irritation with those of inflammation or congestion. At any rate, it is certainly the rule that spinal irritation without spinal inflammation or congestion is accompanied by spinal tenderness, and that spinal inflammation and congestion without spinal irritation is not accompanied by spinal tenderness. Spinal tenderness, however, can scarcely be spoken of as a prominent symptom in spinal irritation. It is often not complained of until it is specially inquired after; and now and then its existence is not even suspected by the patient until he or she is made to wince under pressure applied to the spine. In a few cases which from their symptoms would seem to come under no other head than that of spinal irritation, there is no spinal tenderness—only five such cases are met with among the 148 cases brought together by the brothers Dr. and Mr. Griffin, and these may without difficulty be in great measure explained away; but such cases are
much too exceptional and doubtful to throw discredit on the rule in question, that spinal irritation and spinal tenderness go together. Spinal tenderness, however, does not appear to be equally marked in all forms of spinal irritation. It appears to be much less marked where the irritation shows itself in spasm and prolonged muscular contraction than in the cases where it shows itself in pain; and it is certainly absent in tetanus, which in one sense may be looked upon as the manifestation of spinal irritation in its most aggravated form.

Nervous pains, often in connexion with tenderness in a particular part of the spine.—Nervous pains, neuralgias, in one place or another, often intermittent and more or less regularly periodical, and often shifting suddenly from one place to another, are a very common, perhaps the most common, symptom in spinal irritation. They are often brought on or exaggerated by lifting any weight, by twisting or straining the back in any way, or by any effort, mental or physical: and as often they are relieved, to some extent at least, by lying down. Very often, also, there is tenderness in the portion of the spine corresponding to the insertion of the affected nerves—in the upper cervical region, where the pains are in the scalp (clavus hystericus, megrim, and others), face, or neck; in the lower cervical region, where they are in the upper extremities, shoulders, and upper part of the thorax; in the dorsal region, where they are in the lower part of the thorax and upper part of the abdomen (pleurodynia, gastrodynia, infra-mammary stitch, and others); in the lumbar and cervical regions, where they are in the lower part of the abdomen, hips, loins, and lower extremities. In the majority of cases the pain would not seem to be in the part of the spine which is tender, or in any other part. In some cases there may be aching in some part of the spine, or else a sense of weight and heat; but I am very much inclined to believe that these last mentioned symptoms, and "back-ache" generally, have often to be referred to spinal congestion rather than to spinal irritation in its uncomplicated form. When the spinal tenderness is very great, slight pressure will often cause pain to strike from the tender spot of the spine to the distant seat of pain, or will bring about or exaggerate this pain. This fact is illustrated in the case I have given, and better still in some of the cases related by the Griffin brothers. In one of these cases, for example, where the whole spinal column was found to be acutely tender, "pressure of the first or second vertebra occasioned pain, which shot forwards from the occiput to the brow; a little lower, pain was excited at the larynx; on pressing one of the lower cervical, it occurred at the point where it dips behind the sternum; on pressing the upper dorsal, at the middle of the sternum; from the third or fourth dorsal to the eighth or ninth, it was excited at the ensiform cartilage; yet lower, at the sides; and in the lumbar vertebrae, pain was excited in the iliac and pubic regions" (p. 19). And in another case, where there was some tenderness of the middle cervical vertebrae, and acute tenderness from the fourth dorsal to the eighth or ninth, "pressure on any of those last, especially the seventh or eighth,
brought on violent pain, which darted forwards to the ensiform cartilage. When the last mentioned vertebra was pressed upon, the patient said that she thought her ‘heart would break’” (p. 119). The pain is often curiously localised: sometimes it gives the idea of a nail being driven into the part, as in clavus hystericus; sometimes the feeling produced by it is as if a walnut or other hard substance were pressed under a tight belt; sometimes it is very severe, and neuralgic in its character rather than rheumatic: and not unfrequently, when it has existed some time, the painful part becomes tender on pressure. Most generally this morbid sensation is in the form of pain, but now and then it may take that of cold, tingling, itching, or some other feeling which is disagreeable rather than painful. The amount of constitutional disturbance attending the pain varies very much, but it is usually comparatively trifling, and, as it would seem, quite out of proportion to the degree of suffering.

*Nausea, retching, vomiting, eructation, &c. often in connexion with tenderness in a particular part of the spine.*—These are common symptoms in spinal irritation: next to pain, indeed, they are perhaps the most common. They are also intimately connected with certain forms of pain, especially cephalalgia and gastrodynia, sometimes preceding, sometimes accompanying, but more generally following, the pain. As regards the particular part of the spine which is likely to be tender when the stomach is the seat of irritation, the Griffin brothers say that “nausea and vomiting appear to bear more relation to tenderness of the cervical spine, pain of stomach to tenderness of the dorsal; but that where there was soreness of both, nausea and vomiting was still more frequent, and pain of stomach scarcely ever absent.” The epigastric disorder in these cases is generally accompanied with tenderness on pressure, not merely in the spine but also in the epigastrium and in the left hypochondrium—with those three patches of tenderness which M. Briquet speaks of as the “trépiéd hystérique”—as the tripod upon which the diagnosis of hysteria rests.

*Spasmodic cough, difficulty of breathing, &c. often in connexion with tenderness in a particular part of the spine.*—These again are symptoms which are common enough in spinal irritation, and mostly so, as it would seem, when the tenderness in the spine is in the cervical and upper dorsal region.

*Palpitation, &c. often in connexion with tenderness in a particular part of the spine.*—Palpitation is another symptom of spinal irritation which seems to be oftenest met with when there is tenderness in the upper half of the spine. It seems to be not unfrequently associated with a feeling of epigastric pulsation, and with nausea, vomiting, and other signs of gastric disorder. Vascular throbblings in other places, as in the temples, and “chills and flushes,” and a disposition to syncope, and other signs of disturbed balance in the circulation, may, and often do, go hand in hand with the palpitation, and seem to have to do with the same condition of the spine.

*Irritability of the bladder, often in connexion with tenderness in a
particular part of the spine.—This was a marked symptom in the case which I have related when the seat of spinal tenderness shifted to the lumbar region, and it seems to be a very common, if not a constant symptom, in cases in which the tenderness is in this region.

The connexion of particular symptoms or groups of symptoms with tenderness in particular regions of the spine.—The data best calculated to illustrate this connexion are those supplied by Dr. and Mr. Griffin. These consist of no less than 148 cases, of which 26 are in males, 49 in married women, and 73 in girls. In these 148 cases, the spinal tenderness was in the cervical region in 28, in the cervical and upper dorsal region in 46, in the dorsal region in 23, in the dorsal and lumbar region in 15, in the lumbar region in 13, and in the spine generally in 23. In the following table the prominent symptoms connected with each one of these forms of spinal tenderness is set forth in a way which requires no comment except this—that this grouping of symptoms with tenderness in particular parts of the spine must only be looked upon as approximating to the truth, and that now and then any symptom may appear out of the order in which it is set down.

DISEASES OF THE SPINAL CORD. 647

e. Lumbar region.  
Cases 13 in number. 
Pains in the lower part of the abdomen, testes, or lower extremities, dysury, ischury, disposition to paralysis in lower extremities. ** Retching and spasm of the stomach in one case only.

f. All regions together.  
Cases 23 in number. 
A combination of the foregoing groups of symptoms, one group changing into another as the spinal tenderness becomes more marked in one region than in another.

Prolonged muscular contraction.—This is a very conspicuous symptom in the case which serves as my text, and it is no uncommon symptom in other cases of spinal irritation. The lower extremities appear to be the parts most commonly affected, one or both of them; but the upper extremities can claim no exception, nor even the muscles of the jaws and neck, trismus or torticollis being among the results in this latter case. "Occasionally," says Mr. Teale, "there is an inability to perform complete extension of the elbow, the arm appearing restrained by the tendon of the biceps, pain and tightness being produced in this part when extension is attempted beyond a certain point;" and to this fact I can testify. Moreover, I can testify as to the not unfrequent occurrence of long-continued closing of the fingers and thumb upon the palm. The rule appears to be, for the extremities to be affected before the trunk or head. This contraction, which is generally painless, may be prolonged for weeks or even months continuously, even during sleep, or with occasional intermissions of uncertain duration; and the attacks, primary or secondary, are usually found to begin and end suddenly and unexpectedly. The relations between this form of contraction and that which occurs in other cases, especially in tetanus and in that somewhat vague disorder to which Dr. Trousseau has given the name of tetany (tétanie), are not very easily determined. In tetanus, with very rare exceptions, the contraction is painful, especially in the paroxysmal bouts, and the order in which it attacks the body is different—first, the jaws; then the trunk; and the extremities only at a late period, if at all. In tetany, as in tetanus, the contraction is painful, but the order in which the body is attacked is different to that which is observed in tetanus, centripetal not centrifugal,—first the extremities, then the trunk or head; the contraction, in fact, being confined to the extremities, except in cases of unusual severity. In the way in which it affects the extremities first, and often exclusively, the contraction of tetany agrees with the contraction under consideration, but in other respects it differs. It differs, especially, in being ushered in and accompanied by symptoms which do not seem to form part
and parcel of simple spinal irritation; namely, tingling and some degree of anaesthesia, and also (so it is said) in the form of the contracted hand being peculiar—like that which the hand of the accoucheur takes in order to be introduced into the vagina—and in the possibility of bringing on the contraction by firm pressure upon the principal nerves or arteries of the affected muscles. It may be questioned, however, whether there are absolutely fixed lines of division between these different forms of prolonged contraction, and whether the difference which exists may not be accounted for as the result of different degrees of irritation, affecting, it may be, different parts of the spinal cord. It may be questioned, also, whether a sufficient case is made out for describing tetany as a definite disorder, and whether it is not rather a form of spinal irritation complicated with some graver spinal disease—spinal meningitis, myelitis, spinal congestion—in varying proportions. The association of tingling and numbness with the prolonged contraction is, as it seems to me, a reason for an affirmative conclusion. At any rate, prolonged muscular contraction, be its significance in tetanus or tetany what it may, must be looked upon as a not unfrequent symptom in simple spinal irritation—as a symptom, too, which is usually of no very grave import. Of this there need be no doubt.

No paralysis of the limbs.—In the case I have given in illustration there was great weakness of the legs, and one leg seemed to "drag" immediately before the contractions came on. There was a disposition to paralysis in the legs, but not more than this; nor do I find paralysis of the limbs among the symptoms of spinal irritation strictly so called. There is, no doubt, a connexion between paralysis and spinal irritation which cannot be overlooked; and under that form of paralysis which is known as "hysterical paralysis," and about which more will have to be said in due time, and under spinal irritation, there is a common basis. As it seems to me, however, it is pathologically as well as physiologically incorrect to speak of hysterical paralysis as a symptom of spinal irritation. Also, it seems to me, the right place of this paralysis is after spinal irritation, not along with it, when the capability of morbid action which is implied in the term irritation is worn out; and so in the other exceptional cases in which paralysis is connected with spinal irritation, it will, I believe, be found on careful examination that the paralysis is not a symptom of actual spinal irritation, but of a state of vascular change into which this irritation may issue and has issued—spinal congestion, it may be, or even myelitis.

No paralysis of the bladder or bowel.—The remarks which have just been made apply equally to paralysis of the bladder or bowel. Paralysis in either of these organs, or even a disposition to it, is rarely met with in any case which can be strictly brought under the head of spinal irritation; and in the few exceptional instances which do occur, it is plain enough, when the matter is fairly inquired into, that the boundary has been passed which separates the state of
irritation from the state of exhaustion, and that, in fact, the case is no longer one of simple spinal irritation.

_No numbness._—Numbness, again, is a symptom which is scarcely ever met with in cases to which the name of spinal irritation is strictly applicable, and, when it is met with, it is easily accounted for. In short, the relationship of numbness and paralysis to spinal irritation appears to be one and the same, the numbness and the paralysis being alike connected, not with the state of morbid action called irritation, but with the after-state of morbid inaction for which exhaustion seems to be one of the appropriate names.

_Variability and inconstancy of symptoms._—One most characteristic feature of spinal irritation is the way in which one symptom or group of symptoms may change, and change suddenly, into another symptom or group of symptoms. It is now this disease which is simulated, now that, there being scarcely any disease which may not be simulated: at one time the head is affected, at another the chest, at another the abdomen or the extremities: and the only thing constant among these ever-shifting phenomena appears to be this—that the spinal tenderness changes from one part to another in a manner which is intelligible enough when the connexion of the spinal nerves with the affected part is taken into consideration.

_A nervous constitution._—The subjects of spinal irritation, with few if any exceptions, may be spoken of as hysterical, hypochondriacal, or nervous. They have, in fact, that nervous constitution which Whytt, following in the steps of Sydenham, showed to be the common basis of hysteria and hypochondriasis. First in order among the signs of this constitution comes that sign which Sydenham regarded as pathognomic of hysteria and hypochondriasis,—namely, a proneness to pass, under or after strong emotion or excitement, large quantities of pale limpid urine. Then come other signs scarcely less characteristic: proneness to tenderness, not only in some part of the spinal column, but also in the epigastrium and left hypochondrium—_le trépied hystérique_ of Dr. Briquet already referred to; proneness to sudden and distressing flatulent distension of the stomach and bowels, with loud rumblings and explosions, and with a feeling of a ball rolling about, first in the left flank, and then mounting, or tending to mount, into the throat, where it gives rise to a sense of choking and to repeated acts of swallowing; proneness to bursts of crying and sobbing or of laughing; proneness to sighing, yawning, and stretching the arms; and proneness to fits of convulsive agitation and struggling. Then come a promiscuous series of signs: proneness to erratic pains of a neuralgic character, breathlessness, nervous cough, palpitation, throbbing in the temples, epigastrium, and elsewhere; "flushes and chills," syncope, hiccup, nausea, vomiting, aversion to food or unnatural craving for it, heartburn, oppression at the pæcödia, languor, debility, fidgetiness, tremulousness, vertigo (especially on rising hastily), ringing in the ears, "animus, nec sponte, varius et mutabilis," fancifulness and inability to discriminate
between fact and fiction, undue lowness of spirits or the contrary, and a host of other symptoms whose name is legion. Not only, indeed, is the name of these different symptoms legion, but there is ever going on a process of mutual metamorphosis in the symptoms themselves; and, in conclusion, it is this very hysterical or hypochondriacal variability and mutability of the symptoms which must be looked upon as the great characteristic of the nervous constitution.

2. Post-mortem Appearances.—The morbid structural changes strictly belonging to spinal irritation are nil. The disease is nervous or functional in its character, and on this account it leaves no obvious traces after death. Still, as Dr. Copland wisely says, "an affection which may with justice be viewed as functional to-day—as spinal irritation merely—may be inflammation on the morrow, and rapidly followed by the consequences of inflammation." Such a termination, however, is altogether exceptional: and when it does occur, the history during life will show very clearly that any traces of inflammation which are met with after death are to be ascribed, not to irritation, but to inflammation. How far irritation, which involves in its very essence, as I believe, capillary contraction and bloodlessness, not capillary paralysis and congestion, may involve changes which are opposed to inflammation—deficiency of blood and organic changes brought on by the part being starved for want of blood—remains to be seen. I take it that such changes would have been found if they had been looked for with the same amount of care which has been expended in the search for inflammatory changes: but the investigations have yet to be made which will verify or disprove this conjecture.

3. Causes.—Neglect of gymnastic training, insufficiency of wine or other alcoholic drinks, over-indulgence in sexual matters, onanism, would seem to deserve a conspicuous place among the causes of spinal irritation. It is idle, however, to weigh the importance of particular causes, or even to attempt to individualise them, and it is enough to be content with the broad fact that everything which tends to induce a nervous habit,—that is, everything which exhausts vital power,—must be reckoned as a cause. I believe that the starting-point of the disorder will very often be found in some strain or blow to the back, and I also believe that a congenital predisposition may also be detected in very many cases.

4. Diagnosis.—The fundamental question for consideration in this place is how to distinguish between functional and organic affections of the spinal cord, and this question fortunately is one which is less difficult to answer than it might seem to be at first sight. In fact, the characteristics of spinal irritation indicated by the Griffin brothers, are sufficient of themselves to supply the answer to any one who has tolerably clear ideas respecting the principal diseases with which
spinal irritation may be confounded. These characteristics are:—
"1st. The pain or disorder of any particular organ being altogether out of proportion to the constitutional disturbance. 2d. The complaints, whatever they may be, being usually relieved by the recumbent posture, and always increased by lifting weights, bending, stooping, or twisting the spine. 3d. The existence of tenderness at that part of the spine which corresponds with the disordered organ, and the increase of pain in that organ by pressure on the corresponding region of the spine. 4th. The disposition to the sudden transference of the disordered action from one organ or part to another, or the occurrence of hysterical symptoms in affections apparently acute; and 5th. The occurrence of fits of yawning or sneezing, which, though not very common symptoms, yet, as rarely ever occurring in acute organic disease, may generally be considered as characteristics of nervous irritation."

In the diseases of the spinal cord which have already been under consideration—spinal meningitis, myelitis, spinal congestion, and tetanus—it has been seen that it is the rule for the spine not to be tender on pressure, and in spinal irritation it has been seen that such tenderness is so constant as to deserve being reckoned as the distinctive feature. Here, then, is a point of difference which will serve as a guide to a correct diagnosis in several important cases in which guidance is necessary,—which will serve as a guide in almost all cases except in that with which spinal irritation is most readily confounded. This case, which is strumous disease of the vertebrae, is one in which spinal tenderness is also present, as well as many other symptoms of spinal irritation,—pain in the side, stomach, or bowels, cough, oppression, tightness around the waist, and so on—and in which relief is obtained by reclining. Nay, there may even be in spinal irritation a yielding and projection of the tender vertebrae, with some puffiness of the overlying skin, which simulates in no imperfect manner the earlier stage of angular curvature. There are many resemblances, in fact, but, as Dr. and Mr. Griffin have pointed out, there are also certain differences which are so well marked as not to leave the diagnosis in doubt. Thus it is found:—"1st. That strumous disease of the vertebrae attacks the young, and most frequently those under the age of puberty, who are least of all liable to be affected by spinal irritation. 2d. That disease of the vertebrae, when attacking young girls, is seldom accompanied by symptoms of a purely hysterical character, while any serious irritation of the cord can scarcely exist without them. 3d. That an apparent prominence of the tender portion of the spine, which sometimes exists in cases of irritation, is never strictly angular; for, if four or five of the vertebrae seem to project, the prominence is nearly equal in all, whereas in caries of the bones it is greatest in the middle, the prominence depending, in fact, on a slight puffing of the ligaments or investments of the spine, and not on displacement or curvature. 4th. That absolute paralysis of the lower limbs is a rare consequence of irrita-
tion, and a frequent one of caries of the bones. 5th. That the general health suffers less in the former complaint, and it is not attended with the look of serious organic disease which is indicative of the latter. 6th. That the constitution of the patient may also prove useful as a guide, the disposition to spinal irritation, as well as to scrofula, being hereditary."

5. Prognosis.—However urgent the symptoms may be, the prognosis in spinal irritation is favourable rather than unfavourable. It must always be borne in mind, however, that spinal irritation is a state which may issue in inflammatory or other organic changes in the cord or in its membranes, and that a favourable prognosis must be qualified by this contingency, especially in those cases in which there is some obvious vice of the constitution—scrofulous, gouty, rheumatic, syphilitic, or other.

6. Treatment.—"Local depletion by leeches or cupping," says Mr. Teale, "and counter-irritation by blisters to the affected portion of the spine, are the principal remedies. A great number of cases will frequently yield to the single application of any of these means. Some cases, which have even existed for several months, I have seen perfectly relieved by the single application of a blister to the spine, although the local pains have been ineffectually treated by a variety of remedies for a great length of time." Of the efficacy of blisters in these cases I have had abundant proof. As to the good effects of local depletion I have had less experience, partly because I found that the blisters were sufficient of themselves, and partly because I believe that the state of irritation is associated with a state of capillary contraction and bloodlessness, and not with a state of capillary paralysis and congestion. Still, I can well believe that there are many mixed cases in which irritation has issued in some degree of capillary paralysis and congestion, especially in the skin at the seat of spinal tenderness, and in which this state will be greatly relieved by local depletion.

As regards medicine, I should certainly be disposed to trust most in common tonics—quinine, steel, or cod-liver oil; to the latter in conjunction with some preparation of phosphorus most of all, perhaps. And certainly I should be disposed to fight against pain and spasm, as I have sufficiently explained elsewhere, by remedies which rouse the circulation to greater activity, and not by those which have a contrary action. Nay, I should even have more confidence, as a local application for pain, in some application which would produce a hyperemic condition of the skin, than in any one which had a deadening effect upon the sensitiveness of the part.

It is, no doubt, an indispensable part of the treatment to avoid standing or walking to the extent of producing fatigue, but there would seem to be no necessity, except as a very temporary measure perhaps, to insist upon a recumbent position being retained for any
length of time. Upon this point Mr. Teale says (and he says all that need be said), "When my attention was first directed to this subject, I considered recumbency a necessary part of the treatment: it is, for a moderate length of time, undoubtedly beneficial, and frequently very much accelerates recovery; but subsequent observation has convinced me that it is by no means essential. I have seen several instances of the most severe forms of these complaints, occurring in the poorer classes of society, where continued recumbency was impracticable, which have, nevertheless, yielded without difficulty to the other means of the treatment, whilst the individuals were pursuing their laborious avocations."

As regards diet I have only this to say—that I believe the great thing to be done is to supply wine or some other alcoholic drink as well as nutritious food in sufficient quantity. I believe that nutritious food in itself is not enough. In very many cases it is found that alcoholic drinks are either abstained from altogether or taken in very insignificant quantities from a fear that they will aggravate the pain or spasm, or for some other reason: in very many cases it is found also that relief is obtained only when this practice is abandoned, and the diet made to include at least an average share of the drinks in question. Indeed, the result of my own experience is unequivocal in this respect—that the somewhat bold use of alcoholic drinks is a cardinal point in the treatment of spinal irritation, and that this indication must be fully acted upon if this treatment is to lead to anything like satisfactory results.

Of the spinal maladies remaining to be noticed the principal are these:—General spinal paralysis, hysterical paraplegia, reflex paraplegia, infantile paralysis, haemorrhage, non-inflammatory softening, induration, atrophy, hypertrophy, tumour, concussion, compression, caries of the vertebral column, spina bifida, &c.

VI. General Spinal Paralysis.

There is a form of general paralysis to which Dr. Calmeil gave the name of general paralysis of the insane, and with which all who know anything of insanity are sufficiently familiar. It may co-exist with any form of insanity, but it is most commonly associated with the monomania in which the patient believes himself to be possessed of superhuman power and unbounded opulence. The first signs are likely to be thickness of speech, quivering of the lips and tongue, fumbling and clumsy movements of the fingers, with an unsteady and sidling gait.
Then the urine escapes now and then involuntarily, or even the fæces. Once begun, the downward course of the malady is headlong, and in a few months, in a few weeks it may be, within two or three years at the most, the patient is in bed, altogether without the power of supporting himself on his feet, unable to use his hands so as to help himself in any way, incapable even of turning over in bed much less of sitting up, requiring to be fed like a child, and, when fed, in no small danger of choking if left to masticate the morsels, with urine and fæces escaping under him unheeded, and with every power of body and mind an utter wreck. With few exceptions the thickness of speech shows that the muscles of the tongue and lips are the first to fail, but in fact all parts of the muscular system show signs of weakness about the same time, and it is difficult to fix upon any one part and say that it is affected before the rest. Sometimes, the paralysed muscles become considerably atrophied, but the rule appears to be that such atrophy is less marked than in cases where the paralysis is the result of disease in the spinal cord: always, according to Dr. Duchenne, the paralysed muscles, whether atrophied or not, retain their full share of electric contractility. After death signs of disease are found in the brain, but not in the spinal cord; these signs being increased vascularity, with serous or sero-fibrinous infiltration in the pia mater, in the cortical substance, and in the brain structure generally.

General spinal paralysis is the name used by Dr. Duchenne to describe a form of paralysis which, until he pointed out the differences, was confounded with general paralysis of the insane. Looking hastily at the phenomena of paralysis when clearly developed, it is, indeed, not to be wondered at that these two disorders should have been confounded; but in reality general spinal paralysis, as defined by Dr. Duchenne, possesses peculiarities which are sufficiently characteristic. In general spinal paralysis the mental faculties are natural; in general paralysis of the insane they are fundamentally deranged. In general spinal paralysis the electric contractility of the paralysed muscles is abolished or greatly impaired; in general paralysis of the insane it is intact. In general spinal paralysis the paralysis usually begins in the legs and travels upwards, often remaining in the lower parts of the body a long time before attacking the tongue, face, and upper extremities; in general paralysis of the insane all parts of the muscular system would seem to be affected simultaneously, or, if there be any difference as to time, it is the tongue and the upper parts of the body which are the first to suffer. In general spinal paralysis there is a marked disposition to atrophy in the paralysed muscles and elsewhere, to bed-sores, and to other signs of defective nutrition; in general paralysis of the insane these evidences of wasting are, to say the least, far less conspicuous. In general spinal paralysis the progress of the disease is slow, often extending over several years; in general paralysis of the insane the whole course of the disease is comprised within three or four years at most. 

...general spinal paralysis the post-mortem signs of disease
are in the spinal cord and not in the brain; in general paralysis of
the insane the reverse of this obtains, the cord being healthy and the
brain the seat of disease. Much, no doubt, remains to be done before
it is possible to speak positively as to the character of the diseased
changes in the cord which are met with in general spinal paralysis;
and at present it must suffice to say, that in one case related by Dr.
Duchenne there was softening and injection of the anterior columns in
the cervical region of the spinal cord, and that in one case which I had
the opportunity of examining there was want of proper consistence,
not exactly amounting to actual softening, and a perceptible degree of
atrophy, in these columns throughout the whole of their course from
the middle of the neck downwards. Whether general spinal paralysis
will prove to have that relation to disease of the anterior columns of
the cord which locomotor ataxy has to disease of the posterior columns,
remains to be seen.

General spinal paralysis blends, no doubt, with other spinal diseases,
and its symptoms vary accordingly; but still it occurs with sufficient
frequency in the form described by Dr. Duchenne to deserve the posi-
tion which he assigns to it as an individual malady. There are also
relations equally intimate between general spinal paralysis and cerebral
maladies, and I am very much disposed to think that the cases in which
the mental powers are obviously weakened will be found to be at least
as numerous as those typical cases in which these faculties are natural.
At the same time, it must be borne in mind that in some cases of general
spinal paralysis the mind may seem to be weakened, when in reality
it is not so—that in some cases there may be an air of stupidity, or even
fatuity, arising from the slow play of the features, the thickness of the
speech, the fumbling of the fingers, and like symptoms, which air has
its origin in the paralysed state of the muscles and not in the enfeebled
state of "the man behind the mask."

General spinal paralysis cannot be confounded with local Cruvel-
hier's atrophy, or lead palsy, and it must not be confounded with
the general forms of these maladies. In general Cruvelhier's atrophy,
as well as in local, the atrophy of the muscles is partial, certain
muscles being, as it were, dissected out, and others left untouched,
capriciously; in general spinal paralysis the atrophy is en masse. In
general Cruvelhier's atrophy, what remains of muscle obeys the will
and reacts with electricity properly—there is no paralysis; in general
spinal paralysis there is true paralysis, and the paralysed muscles have
lost their electric contractility. In general lead palsy, also, the his-
tory will be sufficient to prevent any confusion as to diagnosis—the
paralysis at first electing the extensor muscles of the forearm, the blue
line upon the gums, the colic, the constipation, the possibility of lead
contamination, and so on.

As regards treatment there is nothing to be said except that it must
be conducted upon the same principles as those which apply in ana-
logous cases.
VII. HYSTERICAL PARAPLEGIA.*

Paralysis is certainly entitled to a place among the symptoms of hysteria. Dr. Briquet met with it in 113 out of 430 hysterical patients, its seat being in the four extremities and in the principal muscles of the trunk in 6, in the left arm and leg in 46, in the right arm and leg in 14, in both arms in 5, in the left arm only in 7, in the right arm only in 2, in both lower limbs in 18, in the left lower limb in 4, in the feet and hands in 2, in the face in 6, in the larynx in 3, in the diaphragm in 2; and my own smaller experience is more in harmony with these statistics than with the statement of Todd, that the face and tongue escape in hysterical paralysis, that the hemiplegic form of paralysis is less common than the paraplegic, and that "hysterical aphonia" is the form which is most frequently met with.

Hysterical paralysis, so called, is generally met with in persons of a nervous habit of body, and in conjunction with symptoms of an unmistakeably hysterical character. As a diagnostic feature, Todd laid stress on a peculiar expression of countenance, which he denominated facies hysterica—an expression characterised by a remarkable depth and prominent fulness, with more or less thickness, of the upper lip, and by a peculiar drooping of the upper eyelids, and, as it would seem, with good reason. Often, moreover, there is a definite history of symptoms which clearly come within the category of hysterical phenomena—emotional excitability, globus, plentiful gushes of pale urine, and the rest. In diagnosing hysterical paralysis, however, it is not necessary to trust solely, or even chiefly, to evidence such as this, for the paralysis itself is found to have certain features which in themselves are sufficiently distinctive.

Hysterical paralysis is characterised by the paralysis being more or less incomplete, by a marked degree of numbness being associated with it, and chiefly (according to Dr. Duchenne) by the paralysed muscles, which are not wasted, having lost their electro-sensibility without losing their electro-contractility—a loss which, by the way, does not support Sir Benjamin Brodie's opinion that it is the power to will contraction, and not the power of executing the orders of the will, which is at fault in this form of paralysis.

It would also seem to be a peculiarity of hysterical paralysis, as well as of hysterical hyperaesthesia, anaesthesia, and clonic convolution, to affect the left side of the body rather than the right. Thus, M. Briquet found pleurodynia nineteen times, hyperaesthesia and anaesthesia five times, clonic convolution twice, and paralysis thrice as frequent on the left side as on the right side. He found, indeed, a state of things which presents a contrast to what is met with in rheumatism, neuralgia, pleurisy, pneumonia, and other maladies, in all of which it is the right side of the body which is most prone to suffer.

Very frequently, I believe, hysterical paralysis is preceded by

* See also article on Hysteria, p. 315 et seq.
symptoms which come under the head of spinal irritation, and not unfrequently, especially when the upper part of the body is affected, it is ushered in by emotional and other symptoms which may at times deserve to be spoken of as an attack of hysteria.

Hysterical paraplegia agrees in its essential features with other forms of hysterical paralysis. The paralysis is usually incomplete. Numbness of the paralysed parts is a conspicuous phenomenon; as conspicuous, it may be, as the paralysis. The paralysed muscles have lost their electro-sensibility without losing their electro-contractility. The bladder and bowel (as much apparently for want of proper sensibility as from true paralysis) are little under control, if at all; less so, as a rule, than in common paraplegia. The paralysis is often preceded by symptoms of spinal irritation, in the lumbar region especially—spinal tenderness, pains about the pelvis and in the legs, irritability of the bladder, and the rest; and now and then it is ushered in by some ordinary hysterical disturbance of one kind or other. And where one leg only is affected, there would seem to be, as Todd pointed out, a gait which is not less characteristic than that which is seen in common hemiplegia. In common hemiplegia the trunk in walking is first of all inclined to the sound side, and the whole weight of the body made to rest upon the sound leg, and then the paralysed limb is raised from the ground and thrown forwards by swinging it outwardly; the whole series of movements being very like those which are necessary in walking with a wooden leg. In hysterical paralysis, where one leg only is affected, the paralysed limb, instead of being raised from the ground, as in common hemiplegia, and thrown forward by an outward swing, is dragged directly forward, with the foot trailing on the ground.

The prognosis in hysterical paralysis would always seems to be favourable. Sooner or later, in one way or another, a cure is brought about, most tardily; perhaps, in the paraplegic form of the disorder.

As regards treatment, all that need be said is, that general rules must be followed out, and that, if anything special has to be done, most help will probably be derived from sharp faradisation with electrodes which allow the currents to act on the sentient nerves rather than on the muscles—that is, with metal ends rather than with the moistened sponges commonly used. At any rate, sharp practice of this kind has often served to bring about results as sudden and satisfactory as those which have now and then followed the exercise of faith in the power of St. Médard and other kindred agencies.

VIII.—Reflex Paraplegia.

Paraplegia is one of the consequences of primary disease in the spinal cord; of this there can be no doubt. Paraplegia may also be the result of disorder or disease beginning at a distance and affecting the cord secondarily—beginning in the urinary and genital organs.
more especially: of this there can be but little doubt. In the former case the paraplegia is spoken of as centric; in the latter as eccentric or reflex.

The chief characteristics of that form of reflex paraplegia which is associated with disease of the urinary organs—*urinary paraplegia*, as it is often called—the commonest and most important of all the forms of reflex paraplegia, as it certainly is, are these; or at any rate these are those upon which Dr. Brown-Séquard, who has paid much attention to this subject, insists. Usually the paralysis is incomplete both as to degree and extent, some muscles being obviously more affected by it than others. Usually the paralysis is *not* associated either with tingling, or numbness, or anaesthesia. Usually the bladder and rectum are only slightly implicated in the paralysis. Usually there are changes for the better or the worse in the degree of paralysis corresponding to changes for the better or worse in the disease of the urinary organs. Usually there is no marked atrophy in the paralysed muscles. Not unfrequently a cure or marked amelioration in the paralytic condition is brought about by the removal of the disease in the urinary organs. Dr. Brown-Séquard indicates these as the chief characteristics of reflex paraplegia connected with disease of the urinary organs, and of other forms of reflex paraplegia as well, the only difference in the description of these latter forms of disease being the substitution for the term urinary of the name which indicates the starting-point for the paralysis.

Thus defined, reflex paraplegia differs diametrically from the paraplegia produced by myelitis. In paraplegia from myelitis the paralysis is usually complete, and all the muscles are affected equally: not so in reflex paraplegia. In paraplegia from myelitis the paralysis is associated with tingling, numbness, or anaesthesia: not so in reflex paraplegia. In paraplegia from myelitis paralysis of the bladder and lower bowel is a marked phenomenon: not so in reflex paraplegia. In paraplegia from myelitis the paralysed muscles are usually atrophied and degenerated: not so in reflex paraplegia. In paraplegia from myelitis cure, or even improvement, is the exception: in reflex paraplegia it is the rule.

It is, indeed, easy enough to find marked differences between paraplegia from myelitis and reflex paraplegia; but the case is far otherwise when a comparison is instituted between paraplegia from spinal congestion and reflex paraplegia. In reflex paraplegia the paralysis is incomplete, and all muscles are not affected equally: in paraplegia from spinal congestion it is so also. In reflex paraplegia the paralysis is not associated with tingling, numbness, or anaesthesia: in paraplegia from spinal congestion it is the same, with the single exception, that there may be at one time or other a trifling degree of tingling at the extreme tips of the fingers or toes. In reflex paraplegia there are fluctuations in the degree of the paralysis: so also in paraplegia from spinal congestion. In reflex paraplegia there is no marked change in the nutrition of the muscles: so also in
DISEASES OF THE SPINAL CORD

paralysis from spinal congestion. And, lastly, in reflex paraplegia, as in paraplegia from spinal congestion, a cure is neither an impos-
sible, nor even an improbable, event. As to essential characteris-
tics, indeed, I can find marked differences when reflex paraplegia is com-
pared with paraplegia from myelitis, but none when reflex paraplegia
is put in comparison with paraplegia from spinal congestion.

Nor is reflex paraplegia always to be distinguished by being
obviously preceded by eccentric disorder in the urinary organs or else-
where. It is, indeed, as Dr. Gull has well pointed out, "not always
easy to determine at this point whether symptoms have a central or
a peripheral origin. . . . . . There is, perhaps, no fact to be more
insisted upon than the normal dependence of the sympathetic upon
the integrity of the spinal system. As a result of this dependence
we learn that dyspepsia, vomiting, constipation, colic, vesical catarrh,
prostatic irritation, pains in the joints, and many other peripheral
disturbances, may seem to precede the central malady, and to be the
cause of it, when in truth they are its effects." And again: "It is
no new fact in medicine, that cerebral exhaustion may impair the
functions of the cord (especially of the lower segments), and give rise
to precisely those symptoms which have been set down as pathognomic of
urinary paraplegia."

Dr. Brown-Séquard has taken a very different view of reflex para-
plegia to that which is here taken. He regards this disorder as due,
not to spinal congestion, but to a state of the circulation diametrically
opposed to this. He believes that a state of irritation, commencing
eccentrically, is propagated along the vaso-motor nerves, of which the
result is, primarily, contraction of blood vessels in, and, secondarily,
exclusion of the due amount of blood from, one or more of the three
parts following—the spinal cord, the nerves proceeding to or coming
from the cord, the muscles. He believes that the proper activity
of the nervous tissue or muscle is starved into paralysis for want
of blood; and he founds this view on the fact that a state of irri-
tation in the vaso-motor nerves may proceed from a distant point
and produce contraction of the vessels, and upon the fact that
traces of organic disease are wanting after death in many cases of
reflex paraplegia. The argument, indeed, is all but as conclusive as it
is masterly and original. The same evidence, however, admits of a
very different construction, and that even without anything like
special pleading. It is, no doubt, true enough that a state of irritation
in vaso-motor nerves may lead to contraction in blood vessels, and
thereby exclude a due amount of blood from the part to which these
vessels belong; but it is not less certain that the same state of irri-
tation carried beyond a given degree, either in time or in intensity,
may, by paralysing the vaso-motor nerves, lead to relaxation of vessels,
and, thereby, to the admission into them of an undue amount of
blood. Moreover, it may also be assumed, as a thing by no means
improbable, that the contraction of the coats of the relaxed and
paralysed vessels in rigor mortis may prevent any marked traces
of such vascular engorgement being met with after death; at any rate it is impossible to infer, from the absence of such traces of congestion after death, that there was no such congestion during life. In itself, indeed, the evidence adduced by Dr. Brown-Séquard in favour of his theory of reflex paraplegia is in itself insufficient to decide whether his view or that I venture to put in opposition to it is the correct one, for in reality it may be used equally in support of either view. And certainly it would seem to be a collateral objection to the view which connects reflex paraplegia with a state of capillary contraction and comparative bloodlessness brought about by irritation in vaso-motor nerves, that in states where the whole nervous system is in a state of great irritation, as in tetanus, and in the state specifically designated spinal irritation, and where it may be assumed that the vaso-motor nerves participate in this state of irritation, and produce vascular contraction and comparative bloodlessness in the spinal cord and elsewhere, that paraplegia or any form of paralysis is precisely the symptom which is not present. Moreover, Dr. Gull makes some remarks on urinary paraplegia which have an important collateral bearing on the subject in hand, and which tend in no ordinary degree to support the conclusion to which all the previous considerations tend: "If," he says, "we regard the nature of the urinary disease which most commonly leads to paraplegia, we shall find that it is an inflammation, either in the prostate, bladder, or kidneys; and we shall also find, that it is only after chronic inflammation has lasted a long time that the paraplegic weakness supervenes. It is in just those cases where there is most irritation, and but little inflammation, that paraplegia does not occur. Uric acid and oxalate of lime calculi may cause haematuria and any amount of irritation, but unless suppurative inflammation sets in, paraplegia is not produced. A review of all the recorded cases of urinary paraplegia will show that it is the inflammatory condition of the urinary organs which leads to paralysis, and not one of irritation."

In speaking in this manner, however, I do not wish to confound reflex paraplegia with spinal congestion. On the contrary, the more I see of practice the more I am disposed to think that there is a reflex variety, not only in paraplegia from spinal congestion, but in every form of paraplegia; that, in fact, the causes at work in producing all spinal maladies are reflex in their character as well as centric, reflex, it may be, rather than centric.

If the true view of reflex paraplegia be the one which is here taken, it follows that the treatment of that form of this disorder which is defined by Dr. Brown-Séquard will be substantially the same as the treatment of paraplegia from spinal congestion, and not that which has been recommended on the supposition that the spinal cord is starved for want of blood in consequence of its vessels being kept in a state of contraction by irritation of the vaso-motor nerves. Nay, even the necessity to treat eccentric disorder or disease in the urinary organs or elsewhere can scarcely be considered a peculiar feature in the
treatment of reflex paraplegia; for, in fact, it is always an essential part of any sound plan of treatment in any disease of the spinal cord, whether originating in the cord or at a distance from the cord, to make a point of doing everything to remove or mitigate any eccentric malady. It is always necessary to do this, because an eccentric malady, whether primary or secondary to the spinal disorder, or whether having no other than a purely accidental relation to this disorder, invariably reacts prejudicially upon the cord. This eccentric malady must of course be dealt with on general principles, this thing or that being done according as irritation or inflammation may happen to be the predominating condition. In urinary paraplegia, for example, it is very possible that the local application of opium or belladonna to the urethra, as recommended by Dr. Brown-Séquard, may be of much use; this is very possible on any hypothesis: but with respect to the frequent introduction of catheters, with a view to relieve irritation, I think it is difficult to come to a different conclusion to that which Dr. Gull has arrived at. "This course," says this able physician, "is not unattended with danger. There is no part of the treatment which calls for more discrimination. The diseased textures and veins about the neck of the bladder are so prone to suppuration, that the catheter is often a fatal weapon. The few scattered instances, such as that recorded by Dr. Graves, where immediate good effects have followed, have had undue influence towards promoting mechanical interference. Carefully considered, they do not warrant the inference drawn from them. If the urinary passages are so contracted that the bladder cannot empty itself, the catheter is obviously required; but it must be simply prescribed on these grounds. The rule for its use is the same as in the treatment of the aural passages, when the middle ear is diseased. If there be a free exit for the excretions, the less mechanical interference the better. As meddlesome midwifery is bad, so is the meddlesome employment of the catheter in urinary paraplegia. Cases might be quoted where a fatal issue has been induced by the meddlesome interference with a diseased bladder, under the hope of removing some hypothetical cause of reflex irritation."

IX.—Infantile Paralysis.

This disorder, to which attention seems to have been directed first of all by Underwood, Marshall Hall, and Kennedy, is the paralysis (dite essentielle) de l'enfance of several French writers. It attacks children indiscriminately, without any regard to sex, between the age of six months and two years, at the time of the first dentition more especially; and it is the grand source of shrivelled, half-dead limbs, club-feet, and other sad deformities.

Mr. William Adams, who has had ample opportunities of becoming practically acquainted with the history of infantile paralysis, and whose account of this disorder is more to the point than any other with
which I am acquainted, indicates these as the most trustworthy characteristics:—1. The paralysis is usually partial, single muscles or groups of muscles only being affected. 2. The sensation in the paralysed parts is usually perfect, or all but perfect. 3. The bladder and lower bowel are usually not distinctly implicated in the paralysis. 4. The paralysed muscles are at no time rigid. 5. Great improvement or complete recovery is the rule, and not the exception. 6. The paralysis is usually neither accompanied nor preceded by "head symptoms."

The onset of the disorder is generally sudden and unexpected. The child is put to bed well, and in the morning it is found to be paralysed. Or the paralysis may be grafted upon some marked febrile disorder, as gastric or remittent fever, measles, or typhus; or upon some other malady, as hooping-cough and pneumonia. In some cases there may be transitory and trifling feverishness at first, but fever is certainly no essential accompaniment at any time. Now and then, but only in exceptional cases, the disorder may be ushered in by convulsions or drowsiness.

The paralysis has usually a wider range at first than that which it takes afterwards; in other words, the paralysis is more or less general at first, and more or less localised afterwards. Thus it is a common thing for all the limbs to be attacked and for only one leg to remain paralysed, or, rather, to remain partially paralysed, for there is a certain degree of recovery in certain muscles, even in the worst cases. It is the constant rule, indeed, for recovery to be slower in the legs than in the arms, and in certain muscles than in others. Usually the disease does not mount high enough to paralyse muscles whose nerves are given off above the true limits of the spinal cord. There is certainly no loss of sensation in infantile paralysis. On the contrary, as Dr. West remarks in his admirable treatise on the diseases of infancy and childhood, "sensation in the affected limb appears to be exalted when the paralysis is recent, the degree of hyperaesthesia in the early stage being in such cases proportionate to the loss of power which afterwards is apparent." Moreover Dr. West proceeds to say, "In some instances the exaggerated sensibility continues for several weeks, though this is unusual; and when this is the case, the leg being the seat of the affection, and the paralysis incomplete, the existence of hip-joint disease may very likely be suspected. In such a case the child bears all its weight on the healthy limb, turns the foot of the affected side inwards when walking, and stands with the toes of that foot resting on the dorsum of the foot of the healthy side. Still it will usually be found that the exaggerated sensibility of the paralysed limb varies greatly at different times, while that extreme increase of suffering produced in cases of hip-joint disease on striking the head of the femur against the acetabulum by a blow upon the heel, and the fixed pain in the knee of the affected side, so characteristic of diseases of the hip-joint, are absent; and these points of difference will enable you to distinguish between the two affections. One other important means of diagnosis is furnished by the presence or absence of an increased
temperature over the suspected joint, the value of which easy observation in determining the presence or absence of inflammation about any particular spot is dwelt upon by Mr. Hilton in his lectures delivered recently at the College of Surgeons."

The peculiarities of infantile paralysis, so thinks Mr. Adams, point to a special pathology which has yet to be made out satisfactorily. As it seems to me, however, these peculiarities, instead of showing, as Mr. Adams believes, that infantile paralysis is unlike paralysis in adults, only show a close analogy to, if not an actual identity with, the paralysis which has been seen to result from spinal congestion. In infantile paralysis the paralysis is partial: in paralysis from spinal congestion it is the same. In infantile paralysis sensation is exaggerated rather than dulled in the paralysed parts: in paralysis from spinal congestion it is the same. In infantile paralysis the bladder and lower bowel are obedient to the will: so also in paralysis from spinal congestion. In infantile paralysis the paralysed muscles are limber, not rigid: so also in paralysis from spinal congestion. In infantile paralysis recovery more or less complete is the rule rather than the exception: so also, and very much in the same order, in paralysis from spinal congestion. In infantile paralysis "head-symptoms" are exceptional phenomena at any time: so also in the paralysis from spinal congestion. Neither do I know of anything to invalidate the conclusion which those resemblances would seem almost to necessitate—that infantile paralysis, as defined by Mr. Adams, is nothing more than paralysis from spinal congestion.

Moreover, this conclusion is not discredited by the disclosures of morbid anatomy. There were no traces of organic disease either in the spinal cord or brain or nerves in the four cases of genuine infantile paralysis which were examined after death by MM. Barthez and Rilliet, Dr. Fliess, and Mr. Adams, all four most competent observers. The evidence supplied by these cases is indeed purely negative. Nor is evidence more positive to be found in the two cases examined after death by M. Laborde, the writer of a very able treatise on infantile paralysis recently published. In these two cases, without doubt, there were certain organic changes in the spinal cord and in some of its nerves, but these changes are plainly not essential to infantile paralysis as defined alike by M. Laborde and Mr. Adams, for the simple fact is, that the clinical history of these cases is not clearly that of infantile paralysis so defined. In a word, there is nothing in the scanty contributions of the dead-house to show that the very closest relations may not exist between the disorder under consideration and spinal congestion.

The duration of infantile paralysis is very variable. It may pass off in a few days, or even a few hours: it is more likely to occupy several weeks or months in this process of improvement. Improvement, to a greater or less degree, is indeed the rule, and not the exception; and it may even be said that the cases which stop far short of recovery are by no means common. Mr. Adams says, "It is generally supposed
that, unless recovery takes place within a few months, the paralysis is persistent through life; but I have seen many cases in which improvement has proceeded, to a very useful extent, several years after the seizure; and to the truth of this remark my own experience bears ample testimony. Indeed, I should say from what I have seen, that if the paralysed muscles retain their electro-contractility and electro-sensibility, and so show that they have not passed into that state of fatty degeneration into which they always tend to pass eventually, there appears to be scarcely any limit to the time in which improvement, and even complete recovery, is possible.

The groups of muscles most frequently affected in infantile paralysis, according to Mr. Adams, are, 1. The muscles of the anterior part of the leg, forming the extensors of the toes and the flexors of the foot; 2. The extensors and supinators of the hand, these muscles being always affected together; and 3. The extensors of the leg, and with them generally the muscles of the foot, as in the first group. When single muscles are affected, the most likely to suffer are these:—1. The extensor longus digitorum of the toes; 2. The tibialis anticus; 3. The deltoid; and 4. The sterno-mastoid.

The deformities produced by infantile paralysis are most frequently met with in the feet and legs, because these are the parts most frequently affected; and the particular kind of deformity varies, of course, with the muscles involved in the paralysis.

"The most frequent kind," says Mr. Adams, "is that of (1) talipes equinus; and the other deformities occur in the following order,—(2) equino-varus; (2) equino-valgus; (4) calcaneus, or calcaneo-valgus; and (5) talipes varus. When both feet are affected, equino-varus of one foot is generally found with equino-valgus of the other."

Mr. Adams is of opinion that the great cause of the deformities which are met with in infantile paralysis is the "adapted atrophy" of Mr. Paget, this change taking place chiefly in the opponents of the muscles which have suffered from paralysis. If, for example, the anterior muscles of the leg are paralysed, the anterior portion of the foot drops, and the heel is raised, not by active contraction of the posterior muscles—for division or paralysis of one set of muscles does not excite active contraction in the opponent muscles—but in consequence of the position assumed by the foot from its mechanical relations with the leg. Another cause of deformity is obviously atrophy and actual or comparative arrest of development in the paralysed muscles; for, unless the paralysis soon passes off, it is plain that the muscles will not only waste, but be left behind in the rapid process of development which is everywhere at work in a young and growing child. Mr. Adams is also of opinion that the early and late rigidity of Todd and true spasm have very little to do in causing the deformities in question; and so it may be in the deformities connected with that form of paralysis to which he restricts the term infantile—that form which is undoubtedly the common variety of infantile paralysis, and which, as it would seem, is dependent on spinal
congestion. It is very certain, however, that infants and children are liable to more than one form of paralysis, and that there are deformities associated with rigid as well as with flaccid muscles. It is very certain that this rigidity may be either "early" or "late," as distinguished by Todd, or even still more decidedly spasmodic than that form which is called "early rigidity." In a word, infantile paralysis is a designation as little to be defended as would be the term adult paralysis; for on inquiry it is found that in children, as in adults, there is more than one form of paralysis, and that all the forms which may happen in adults may be repeated in children. The form of paralysis which has been described as infantile is unquestionably the commonest, and the other forms are so uncommon as to be little more than exceptional; and this, in fact, is all that can be said to justify the notion that infantile paralysis is a definite disorder of the spinal cord peculiar to infants.

The treatment of the deformities, especially of club-foot, resulting from the so-called infantile paralysis, is a subject of much practical interest and difficulty. Mr. Adams says: "The probability of benefit in such cases by any surgical procedure seems scarcely ever to be entertained. The existence of paralysis is supposed to contra-indicate any surgical interference; but, from these apparently hopeless and essentially incurable cases some of the most striking and most valuable results of surgery are obtained by a combination of surgical and mechanical treatment. Mechanical aid, alone, is frequently sought from the instrument-maker, but his art is powerless when any considerable amount of deformity exists; and it is only by a scientific combination of surgical and mechanical skill that much good can be effected. In all these cases the treatment essentially consists in the removal of existing deformities by tenotomy and mechanical means, and a subsequent compensation for the existing paralysis by mechanical support, varying in different cases according to the extent of the paralysis." And no doubt very satisfactory results are obtained by those means. At the same time it is certain that in many cases very satisfactory results may be obtained without tenotomy, and without apparatus, by means used with the view of bringing back power into the paralysed muscles—electricity, movements of various kinds, shampoos, and others; and my own experience has convinced me that this fact is not yet sufficiently recognised and acted upon in practice.

* There are certain forms of paralysis in which the paralysed muscles do not react to the most powerful induced electric currents, but react energetically to a galvanic current of low tension, slowly interrupted (the table current of Remak). The diagnostic and therapeutic bearings of this fact have yet to be worked out, but so far the therapeutic promise is good. The phenomenon in question has been already observed in several very different cases—in facial palsy (first noted by Baileracher), in certain cases of infantile paralysis (discovered by J. Netten Radcliffe, of London, and Hammond, of New York, independently of each other), in certain cases of local palsy, e.g., palsy of the extensors of the fore-arm and of other muscles, from lead-poisoning (Bruckner and J. N. Radcliffe), in paralysis of the deltoid, not from lead (J. N. Radcliffe), in certain cases of muscular atrophy (J. N. Radcliffe), and in paralysis from traumatic injury of a nerve (Bruckner).
That in many cases neither tenotomy nor apparatus can be dispensed with I fully believe: that in all cases the electrical and gymnastical parts of the treatment are of primary rather than of merely secondary importance I am every day more and more convinced, because every day I meet with instances of muscles which I should once have looked upon as hopelessly paralysed being resuscitated by those means. Indeed, I cannot but think that so long as institutions specially set apart for orthopaed purposes are wanting in properly furnished electrical rooms and gymnasiums, there must be in some essential points a necessity for a great reformation in orthopaedic practice.

X.—Hæmorrhage.

Blood may be diffused into the substance of the cord between the arachnoid and pia mater, into the sac of the arachnoid, between the dura mater and arachnoid, or between the dura mater and the osseous canal—anywhere in or about the spinal cord, in fact. Hæmorrhage in the substance of the cord, the hæmatomyelic of Ollivier, may be a consequence of myelitis, the blood vessels breaking up in the softening of the cord, and so allowing the blood to escape. It was so in the acute case which I took as my text when speaking of myelitis, for here the blood was collected at one point in the softened nerve matter to an extent which at first sight suggested the idea of hæmorrhage into the cord rather than that of myelitis. Hæmorrhage under or upon the spinal membranes, the hæmatorachis of Ollivier, may be a consequence of cerebral hæmorrhage, the blood overflowing from the cranial into the spinal cavity, and perhaps mixing with the spinal fluid; or it may result from spinal congestion, spinal meningitis, myelitis, tetanus, hydrophobia, and certain other maladies. All these cases, however, are so uncommon as to be little more than exceptional. In fact, hæmorrhage either into the substance of the cord, or under or above the spinal membranes, except as the result of some accidental injury to the spine, as in death by hanging, or in cases of still-birth where it has been necessary to employ much force to bring about the delivery, is, to say the least, a very uncommon affection.

The symptoms of spinal hæmorrhage are by no means clearly marked. Sudden and acute pain in the spine at the seat of the effusion, and sudden paralysis and loss of sensation, more or less complete, in the parts below this point, appear to be the chief symptoms where extensive hæmorrhage has taken place into the substance of the cord. Sudden and acute pain in the spine would also seem to be a prominent symptom in hæmorrhage below or above the spinal membranes, but not sudden paralysis and anaesthesia. In this latter case, indeed, instead of paralysis there have been some convulsive or spasmodic symptoms, and instead of anaesthesia some hyperaesthesia. In some cases, as in one quoted by Dr. Copland, the
pain may be not in the back, but at a distance from the back; and in other cases, and this not unfrequently, pain may be greatly masked by the shock of the accident which has caused the haemorrhage, or by the shock attendant upon the laceration of the spinal cord by the effused blood. When the haemorrhage is in the medulla oblongata, and high up in the cord, the symptoms may be rather like those of epilepsy than anything else—loss of consciousness, convulsion more or less general, choking noises, and the rest—and this equally whether the blood is effused into the substance of the cord or around it: and this fact suggests the possibility, to say the least, that the convulsive or spasmodic symptoms, which have by some writers (on what to me seem to be insufficient grounds) been supposed to distinguish haemorrhage under or above the spinal membranes from haemorrhage into the substance of the cord, may in reality be due to irritation transmitted to the medulla oblongata and upper part of the cord, and not to irritation acting upon the membrane or membranes. Moreover, when the haemorrhage is high up in the cord priapism and distress of breathing are found to figure conspicuously among the symptoms, as they do also in other cases where this part of the cord is damaged by disease or injury. In a few instances, the symptoms of spinal haemorrhage are preceded by symptoms indicative of spinal congestion, or inflammation, or irritation.

Remains of old apoplectic cysts, similar to those so often found in the brain, have been met with in the spinal cord, even in the medulla oblongata and upper part of the cervical region; but these signs of partial recovery are, to say the least, altogether exceptional. Indeed the mischief done by the haemorrhage is generally not only irreparable, but very speedily fatal, and that too in spite of everything that can be done to promote recovery.

XI.—Non-inflammatory Softening.

Two well-marked varieties of softening of the spinal cord are detected by the naked eye—the red and the white. In both varieties the microscope brings to light broken down nerve-tissue mixed up with a number of bodies known as granule masses—large bodies, whose principal constituent is fat; black-looking, from not transmitting light; and somewhat like mulberries, from being built up of a number of round bodies or granules. “It was once thought,” said Dr. Wilks, “that these masses denoted inflammation. But you find them in any degenerating part, as a decaying strumous gland, or a cancerous tumour, or a phthisical lung: and the question of their formation in the brain or cord is not yet answered; whether they originate in inflammatory cells, or are the natural cells of the nerve-structure degenerated. In some you may still see a wall and a nucleus, which points to the former opinion as the more correct.”
The red variety of softening is often in parts yellow rather than red: the redness being due to increased vascularity or effused blood corpuscles, one or both; the yellowness to the presence of fibrillated tissue, nucleated fibre, pus-corpuscles, or some other form of distinctly inflammatory product. In a word, there can be no doubt of the inflammatory origin of the red variety of softening. In the white variety of softening, on the other hand, there are generally an atheromatous state of the vessels and other signs of true degeneration, the vascularity is evidently diminished, and there is an absence of those distinctly inflammatory products which have just been enumerated. It would seem, indeed, that the white variety of softening differs essentially from the red, in that, instead of being the result of inflammation, it is brought about by the parts being starved and atrophied for want of blood. With respect to the reality of these differences between these two varieties of softening there appears to be little or no reason for doubt: at the same time it must not be forgotten that it is not always easy to draw the line between these two varieties, and that they both may exist together in the same cord.

The symptoms of non-inflammatory softening would seem to be identical with those of the more chronic forms of myelitis. The more tardy the development of these symptoms, and the older the patient in years or in constitution, the more likely is the case to be one of non-inflammatory softening: and this is all that can be said in the matter of diagnosis. Practically, however, this want of definiteness is of no moment; for in the chronic form of myelitis the degenerative process has more to do in bringing about the diseased changes in the cord than the inflammatory, and more to do also in supplying the indications for treatment. Nay, it may even be held that the same remark applies to some extent to the more acute forms of myelitis as well as to the more chronic, for it is with the ruin rapidly produced by the inflammation rather than with the inflammation itself that the practitioner in medicine has to cope almost, if not altogether, from the very onset of the disease.

**XII.—Induration.**

Like the opposite condition of softening, induration (sclerosis) of the spinal cord is one of the consequences of myelitis, chronic or acute; of the chronic form more especially. Induration of the cord is generally associated with atrophy—atrophy often more marked in the white matter than in the grey—and with a condition so curiously bloodless that a section is not unlike that of white of egg boiled hard. In its highest degree the cord may have a leather-like or fibro-cartilaginous hardness and consistency. Induration is a much less common change than softening: it has no symptoms by which it can be distinguished from softening: and it
is often met with when it was not expected, and under very different circumstances, as after acute myelitis on the one hand, or after long-standing epileptic disease on the other.

XIII.—ATROPHY AND HYPERTROPHY.

Atrophy of the spinal cord, like atrophy of the brain, is one of the changes which must be looked upon as natural to old age. In elderly persons, indeed, the cord becomes shorter and narrower and firmer, the spinal fluid increases in quantity, so as to fill the space left vacant by the shrunken cord, and the spinal nerves are sensibly wasted at both their roots. All this has been abundantly proved by Chaussard, Ollivier, and others. Atrophy, more or less general, is also associated with many forms of paralysis in which the cord has been long left in a state of comparative functional inactivity; and local atrophy is one of the consequences of tumour, displaced vertebrae, or anything which exercises pressure upon the cord. Of partial forms of atrophy resulting from disease, the only one about which there is any certain knowledge is that which is associated with the disease called locomotor ataxy—namely, atrophy of the posterior columns; and about this form enough has already been said in a separate Article.

In a few instances the spinal cord has been found to be so much enlarged, apparently by a true hypertrophy of its natural tissues, as to occupy the whole space of the vertebral canal; but most generally what seems to be hypertrophy at first sight is due, chiefly at least, to congestive swelling and edema. True hypertrophy has been met with in the foetus: it occurs mostly in children: and it presents, so far as is known, no symptoms by which it can be recognised. Hypertrophy of the brain is a very uncommon affection, but it is common as compared with hypertrophy of the spinal cord.

XIV.—TUMOUR, &c.

“Tubercle and cancer,” says Rokitansky, “are frequent in the brain, unfrequent in the spinal cord. Tubercle I have observed only in combination with other advanced tuberculoses. Its principal seat is the cervical or lumbar portion of the cord, where it sometimes occupies the white fibres, sometimes the grey substance. As in the brain, it leads to inflammation (red softening) and to yellow softening. I have never seen a tuberculous cavity in the cord. Sometimes several tubercles are grouped together, none exceeding the size of millet or hempseed; at other times only one exists, which is of large dimensions, equalling a pea or a bean. Exclusively of several cases of circumscribed callous induration of the white columns, as to the cancerous nature of which I am still in doubt, I have met with
but one case of cancer of the cord. It was a solitary nodule of medullary cancer. Olivier mentions several examples of diffused carcinomatous growths, as well as of the so-called colloid cancer. Among the entozoa I have repeatedly seen the cystocercus in the cervical portion of the spinal marrow. The acephalocyst sacs, as far as has been observed, have no connexion with the cord; their nidus is even outside the dura mater. In one case the cyst forced its way into the cavity of the arachnoid.

Nor are exostoses, cartilaginous growths, or aneurisms frequently met with in positions which can exercise pressure upon the spinal cord. Cartilaginous growths, or rather bony plates, it is true, are not unfrequently met with in the visceral arachnoid of the cord—a condition which appears to be rarely met with in the brain; but these growths or plates can scarcely be brought under the head of tumours. Except, perhaps, in connexion with serofulous disease of the vertebre, the pia mater of the cord is not the seat of tuberculous deposits; and here again is another point of difference between the pathological history of the spinal cord and the brain, for it is a well-known fact that the pia mater of the brain is a favourite seat of these deposits.

The symptoms produced by tumour vary greatly. Neuralgic pain in the back, over the seat of the tumour, appears to be an almost constant symptom. "Pain," says Dr. Reynolds, "is more marked in cases of carcinoma than of tubercle." If a particular nerve be irritated by the tumour, there may be pain, tingling, or some other anomalous sensation in the part or parts supplied by its sentient fibres, or some morbid form of contraction in the muscles supplied by its motor fibres. If a particular nerve be pressed upon more decidedly by the tumour, there may be local anaesthesia, or paralysis instead of morbid sensations or muscular contractions. It is but seldom, however, that these symptoms of irritation or pressure are so strictly localised; and, in fact, the presence of the tumour is made known usually only by more general symptoms of irritation, or compression, or inflammation, which, instead of being in any way pathognomonic of tumour, may arise from many other causes. "There is, indeed," as Dr. Gull says, "no symptom, or single group of symptoms, which, taken alone, can serve as a secure basis for diagnosis." Tuberculous or carcinomatous deposits elsewhere, with signs of the peculiar dyscrasia of tubercle or cancer, aneurism elsewhere, nodes elsewhere, may help to a diagnosis by showing that symptoms which appear to point to a tumour may have such a cause, and at the same time may supply some information as to the special character of the tumour; but this possibility of help in diagnosis is too remote to be of much practical value, if any. It may be supposed that any serofulous deposit in the cord is more likely to occur in children, and any cancerous growth in older persons; but even this rule has too many exceptions to make it of much use.
Concussion of the spinal cord, like concussion of the brain, is the result of a fall from a height, a blow on the back, or some other accident, and its symptoms vary with the intensity of the shock. Sudden paralysis and loss of sensation, more or less complete, with some inability to pass water or to prevent the escape of flatus or feces, are the more special symptoms. Sudden and marked failure in the circulation and respiration, as shown by pallor, feebleness of the pulse, diminished temperature, slow and shallow breathing, and other signs of common shock are also associated with the more especial symptoms. Great pain along the spine or in some part of the spine has been considered as one of the symptoms of spinal concussion; but neither pain nor spasm are met with in the cases which I have examined; and Dr. Reynolds comes to the same conclusion, for, speaking of these cases, he says: "There is in them neither marked pain nor spasm." Indeed, in the majority of cases the patient is obviously rendered incapable of experiencing either pain or spasm by being stunned.

The symptoms of spinal concussion not unfrequently issue in those of spinal congestion, or myelitis, or spinal meningitis, or else death without any signs of reaction may be the result. Often, without passing into any definite disease, the cord, even after what might at first seem to be only a slight degree of concussion, may not recover its former power perfectly, the patient ever afterwards being weak in many respects, especially in his legs and bladder. Indeed, concussion of the spine sufficiently severe to produce at the time any marked degree of paralysis in the limbs and bladder and lower bowel, with loss of sensation, is certainly a very grave matter, and it may be questioned whether in such a case recovery is ever more than partial.

The appearances after death may present nothing unnatural, or they may be those of haemorrhage more or less extensive. It is very possible that the cases in which severe pain in the back was a symptom would prove, if all the facts were fully known, to be cases in which the symptoms of concussion were mixed up with those of haemorrhage: at any rate, there was haemorrhage in one case of spinal concussion in which pain in the spine was a conspicuous symptom, which case came under my own notice not long ago. In fatal cases, in which the reaction after the concussion has issued in inflammatory and other changes in the cord, these changes will be met with after death; and if fracture or dislocation of the vertebrae was produced at the time of the concussion, the evidence of such injury will of course not be wanting.
XVI.—Compression.

When the spinal cord is compressed by a dislocated or fractured vertebra, by a tumour, by a bullet, or in any other way, the symptoms will of course vary with the seat and degree of compression. The symptoms will, in fact, be as variable—for they will be the same—as those which are produced by experimental division of the parts compressed, and about which more than is convenient had to be said in the preliminary remarks. All, therefore, that is necessary here is to refer to those preliminary remarks for the information which may help to make the symptoms of compression intelligible, and, in passing, to express a hope that trephining or other operative procedures which have been recommended and practised in certain cases of spinal compression may not be altogether unjustifiable.

XVII.—Caries of the Vertebral Column.

This disease is usually limited to the bodies of the vertebrae and to the intervertebral substances, but sometimes it extends backwards to the arches and processes of the vertebrae as well. It commences, very generally, in the middle dorsal region, and, as generally, it does not extend beyond this region; but there is no part of the spinal column in which it may not begin, or to which it may not extend: it invariably, when sufficiently advanced, gives rise to "angular curvature," or projection directly backwards, of the diseased part of the spine, this deformity being due to the way in which the thinned and diseased bodies of the vertebrae become crushed in under the weight of the upper part of the body. In the great majority of cases caries of the vertebrae is an unmistakably strumous affection, being neither more nor less than tuberculous infiltration of the bodies of the vertebrae; and the changes in the bone are due to the melting down of this deposit rather than to any strictly inflammatory process.

The earlier symptoms of caries of the vertebrae are not at all well marked. Of these the most conspicuous must be reckoned—weakness in the back, generally in the dorsal region, with aching or pain, more or less severe, in the weak part, causing a disposition to lean forwards and to use the arms as props; some prominence of the spinous processes of the weak and painful part of the spine, with some puffiness of the overlying skin; a feeling of undue heat, or even burning, in the weak and painful and prominent part, which is not felt in other parts of the spine, when a sponge soaked in moderately warm water is passed down the spine; and a state of tenderness on pressure or percussion, which is equally restricted to the same weak and painful and prominent part. Afterwards, when the disease is more-advanced, there are more marked symptoms, namely these:—unmistakable, "angular curvature," the formation of abscess, slight
hectic in the evening, a feeling of constriction around the waist, it may be, and still later, more or less paralysis of the legs, more or less loss of control over the bladder and bowel, and other symptoms indicative of secondary myelitis or spinal meningitis. Abscess may be one of the earlier symptoms preceding any obvious deformity, or it may not occur at all. In fact, abscess appears to be a symptom of strumous disease of the vertebrae exclusively, and not of the non-strumous variety of caries. When it does occur, which is certainly in the great majority of cases, there is usually some diminution of pain and other evidences of irritation. When it does occur, as is well known, it generally makes its appearance at a distance from the diseased vertebrae, most commonly as "psosas abscess" in the groins, but by no means exclusively in this form and locality. It is seldom that the spinal cord becomes compressed by the giving way of the bodies of the vertebrae in the progress of the disease: but sooner or later it almost constantly happens that the cord or its membranes opposite the diseased vertebrae become the seat of inflammatory changes, which changes, rather than the drain from an abscess, are indeed the reason why, in so many cases, sooner or later, caries of the vertebrae proves to be destructive to life.

The diagnosis between "angular curvature" from caries of the spine, and the curvatures forward, backward, and sideways without other structural changes in the vertebral column than those of simple adaptation to the altered position, is not very difficult. These latter curvatures, in fact, want all the special and grave features which have been indicated as characterising the former. Nor yet is the diagnosis difficult between "angular curvature" in its earliest stage and spinal irritation, with which it is sure to be associated, and with which there is certainly no small danger of its being confounded. This topic has been already touched upon when speaking of spinal irritation, and here it is enough to say that the occurrence of the symptoms which are present in the beginning of caries of the vertebrae (which are no other than those which may belong to simple spinal irritation), in children or youths of a manifestly scrofulous habit—at an age, that is to say, and in a habit, in which symptoms of simple spinal irritation are not likely to be met with—are sufficient to do more than create a bald suspicion of the existence of disease of the vertebral column.

The prognosis of caries of vertebrae is always bad enough. A hump-back is the best result to be hoped for. The end to be aimed at in treatment is, of course, to promote ankylosis of the diseased bones of the vertebrae by allowing them to fall together—by favouring, that is to say, the deformity which is inevitable by letting the back bend and not by trying to prevent it by keeping the back straight,—and to keep up the strength in every way. But these are matters which I cannot touch upon without trespassing upon the domains of surgery, and I therefore leave them to those who are better able, and whose right it is, to deal with them.
XVIII.—Spina Bifida, &c.

The commonest congenital affection to which the spinal cord is liable is dropsy, or hydorachis, and of this dropsy *spina bifida* is the variety most frequently met with, and of most practical interest. The spine is bifid in this disorder from the non-development or separation of the spinal processes and laminae, and the consequence of this malformation is that an opening is left through which, very often, the dropsical fluid presses outwards, and distends so doing the integuments and subjacent tissues into an hernial tumour. Very generally congenital hydrocephalus is associated with congenital hydorachis. The fluid in hydorachis is precisely of the same constitution and character as that which is met with in hydrocephalus: it varies in quantity from a few ounces to several pints: it accumulates between the arachnoid and pia mater, in the arachnoid sac, in the central canal of the cord, and even outside the dura mater, sometimes in one place, sometimes in another, sometimes in more places than one. The hernial tumour into which this dropsical fluid bulges outwardly varies greatly both in position and size, and in the condition of its coverings: it is almost invariably met with in the lumbar region, but it may be in any region: it is usually of the size of a walnut or orange, but it may be as large as a child’s head, or even larger: it may be single or multiple: its bulk may vary considerably under different circumstances, or not at all, becoming, if it vary, fuller and more tense if the position of the child be made such as to cause the fluid to flow into it, emptier and flaccid if this position be altered so that this fluid may run out of it, or if pressure be made upon it so as to bring about the same result: it may swell during expiration and fall during inspiration: it may present distinct fluctuation or none at all; and the skin over it may be sound, thickened, inflamed, ulcerated, gangrenous, covered with tufts of hair, and so on. The dura mater and its lining of arachnoid membrane always enter into the composition of the coverings of the tumour, and these are the only constant elements in these coverings. In the lumbar region, the cord and its nerves, which are generally rudimentary, are out of the tumour altogether: in the cervical and upper dorsal region, on the contrary, it is no uncommon thing for the cord and its nerves to be adherent to the walls of the tumour.

In spina bifida the lower limbs are generally paralysed as well as the bladder and lower bowel, and not unfrequently there is, in addition to the spinal deformity, deficiency of the abdominal walls, hernia of the bladder, imperforate anus, &c. But few cases recover, or even improve, death happening generally at an early period either in convulsions or from spinal inflammation, the immediate cause often being the bursting of the tumour: still there are cases on record in which life has been prolonged—and this too with tumours of no small
DISEASES OF THE SPINAL COLUMN.

size—not only for a few months, but for 17, 18, 19, 21, and even 50 years.

There is little to be done for the relief of spina bifida. Pressure on the tumour by means of an air-pad and suitable bandages can do no harm; and occasional punctures with a grooved needle, as recommended by Sir Astley Cooper, may be a justifiable measure. Even cures have resulted from a combination of these punctures with pressure. "All the plans of treatment," says Mr. Erichsen, "by which the tumour is opened and air allowed to enter it, are fraught with danger, and will, I believe, inevitably be followed by the death of the child from inflammation of the meninges of the cord and convulsions."

There are several other congenital affections of the cord, of which the best account is still to be found in the classical pages of Ollivier. The cord may be entirely absent (amyélie); or it may be imperfect (atelomyélie). Of the imperfect forms of cord there are several varieties. The upper part may be wanting, as in anencephalous and acephalous monsters. The cord may be bifurcated at one extremity or the other, at the upper extremity in monsters with two heads and one body, at the lower extremity in monsters with one head and two bodies. It may be double. It may vary greatly in dimensions, being larger or smaller, longer or shorter than natural—longer, for example, in monsters with tails, shorter in monsters of a contrary sort. It may, as in one form of hydrorachis, be little more than a long bag in consequence of the distension of the central canal of the cord with the dropsical fluid. Or it may be discoloured, as it is in the state which Ollivier designates kirronese or coloration ictrique. These malformations or morbid conditions, however, are of theoretical rather than of practical interest: and therefore they do not form fit subjects for further notice in an article like the present, which has solely a practical end in view.
DEFINITION.—An acute, epidemic disease, characterised by profound disturbance of the central nervous system, indicated, at the outset, chiefly by shivering, intense headache or vertigo, or both, and persistent vomiting; subsequently by delirium, often violent, alternating with somnolence, or a state of apathy or stupor; an acutely painful condition with spasm—sometimes tetanoid—of certain groups of muscles, especially the posterior muscles of the neck, occasioning retraction of the head; and an increased sensitiveness of the surface of the body. Throughout the disease, there is marked depression of the vital powers; not unfrequently collapse; and in its course an eruption of vesicles, petechiae, or purpuric spots, or mottling of the skin, is apt to occur. If the disease tend to recovery, the symptoms gradually subside without any critical phenomena, and convalescence is protracted: if to a fatal termination, death is almost invariably preceded by coma. After death, the enveloping membranes of the brain and spinal cord are found in a morbid state, of which the most notable signs are engorgement of the blood-vessels, usually excessive, and an effusion of sero-purulent matter into the meshes of the pia mater, and beneath the arachnoid.†

SYNONYMS.—(a) Technical:—Cerebro-spinal fever (Royal College of Physicians); cerebro-spinal arachnitis; typhus syncopalisis; tifo apoplettico tetamico; typhus cerebro-spinal (Boudin); cerebral typhus; epidemic meningitis (Stillé, U.S.); petechial fever (G. B. Wood, U.S.); fever with cerebro-spinal meningitis (S. Gordon); malignant purpuric fever (W. Stokes); malignant purple fever; nervo-purpuric fever (Mapother); malignant purpurae (M. Swinney); pestilential purpurae

* At the time that the first volume of this System of Medicine was arranged, the nosological position of the disease described in this chapter was not sufficiently ascertained for it to be enumerated among the "general diseases." It is placed now with the affections of the nervous system to which it bears the closest relationship.—Editor.

† Since the completion of this article the Royal College of Physicians, in its "Nomenclature of Disease," has adopted the following designation and definition of this malady: "Cerebro-spinal Fever. A malignant epidemic fever, attended by painful contraction of the muscles of the neck, and retraction of the head. In certain epidemics it is frequently accompanied by a profuse purpuric eruption, and occasionally by secondary effusions into certain joints. Lesions of the brain and spinal cord and their membranes are found on dissection."
(Banks); febris nigra (R. D. Lyons).—(b) Popular:—Spotted fever (New England); cold plague (Southern States, U.S.); Kolik, Nacken-starre, Genickkrampf (Germany); Nacksjuka, Dragsjuka (Sweden).

Description of the Disease.—1. General Symptoms:—Epidemic cerebro-spinal meningitis is observed in three principal forms: (a. Simple), in which the symptoms indicative of disorder of the nervous centres predominate throughout the whole course of the disease; (b. Fulminant), in which the depressed state of the vital powers, with profound blood-change—as shown by hæmorrhage of various forms into the cutis—characterise the disease; and (c. Purpuric), in which the cerebro-spinal symptoms and the symptoms which mark blood-change (petechie, purpura, vivices, &c.), and flagging of the vital powers, occur together. The proportion in which the three forms of the disease are manifested varies considerably in different epidemics. In every outbreak cases are observed which link, by insensible gradations, one form with another; while in other, and rarer cases, the characteristic symptoms of the three forms are merged together. Continental and American writers have described an abortive form of the disease, the term being given (a) to certain anomalous symptoms observed in communities among which the disease is active: and (b) to sundry characteristic symptoms of the malady of transitory duration: such as severe cephalalgia; a sense of dragging at the back of the neck, or actual slight retraction of the head; cardialgia, enteralgia;—these symptoms often ending contemporaneously with the appearance of profuse perspiration, or epistaxis.

(a.) Simple Epidemic Cerebro-spinal Meningitis.—In the majority of the cases before the onset of the disease the patient suffers from more or less indisposition. There are discomfort in the head, neuralgic pains in the back, the principal groups of muscles, and the abdomen; failure of the appetite, indifference to exertion, perhaps also slight shiverings, and a quasi-febrile state. These indications of disordered innervation may persist from three to seven days, or be manifested only during a few hours, before the confirmed malady fully declares itself. But in numerous cases the onset of the disease is sudden and characteristic. In both classes of cases the accession of the malady is declared by similar well-marked signs. Acute shivering is followed or accompanied by severe, commonly intolerable, headache or vertigo, or both; and after a short interval, or contemporaneously, profuse and irrepressible vomiting takes place, rarely preceded by nausea. Or vomiting may be the initiatory symptom, the shivering, headache, or vertigo following quickly after. The intensity of the symptoms marking the onset of the disease is remarkable and characteristic. The sickness is often, and from the outset accompanied by severe abdominal pain, apparently neuralgic; and not unfrequently this pain precedes the disorder of the stomach, as the cephalalgia precedes mental confusion. In like manner, the shivering ushers in, or is accompanied by, an acutely painful state of the muscles, more
or less general, the forerunner of spasm. Cephalalgia and delirium, abdominal neuralgia and vomiting, and myalgia and spasm are the principal morbid factors of simple epidemic cerebro-spinal meningitis. They distinguish the malady, and the varying prominence with which they are met in different outbreaks gives rise to many diversities in the grouping of symptoms during the progress of the disease. The onward course of the disorder is usually rapid. The headache continues, often without a lull; vertigo occurs frequently; and after the lapse of a very brief period, measured usually by a few hours, the mind becomes confused, and, in some cases, a state of restlessness supervenes not unlike that observed in delirium tremens. The mental confusion assumes the form of muttering delirium, with periods of somnolence, often interrupted by cries provoked by the intense cephalalgia, or by the neuralgic pain elsewhere; or the patient falls into a state of apathy or stupor, from which he may be partially roused, but into which he relapses when left undisturbed, the mind acting as in a dream; or there is acute and violent delirium. Contemporaneously with, or immediately prior to, the mental disturbance, the painful state of the muscles increases, certain groups being more manifestly affected than others, especially the posterior muscles of the neck, the muscles of the spinal column, and those of the lower extremities. The pain, often of an acutely neuralgic character, shoots along the spine and limbs, and across the walls of the abdomen. Partly as a voluntary action, partly as a consequence of spasm of the painful muscles, the head is drawn backwards. The retraction thus arising is one of the commonest and most characteristic symptoms of the disease. As the malady advances an actual or apparent tetanoid contraction of other groups of muscles may occur, the trunk most frequently being curved backwards, and the legs bent upon the thighs. At the same time there may be fleeting spasmodic action of some of the muscles of the face, and occasionally of the eyeballs; or in some cases tonic contraction of these muscles, giving rise to the so-called sardonic laugh, or to persistent strabismus. In many cases cutaneous sensibility is much exaggerated, and very frequently a vesicular or roseolar eruption is developed, the former particularly about the lips. The aspect of the patient as the disease advances is dependent upon the degree of pain, the state of delirium or stupor, and extent of spasm which may be present. The countenance is rigid and contracted, the expression of face betokening acute pain; or it is dominated by the delirious fancies; or reflects the mental torpidity; or is distorted by spasm. There is frequently a slight suffusion of the eyes, altogether different from the dusky appearance of typhus; and the face is commonly pale and sunken, seldom and only transitorily flushed and swollen, except when affected more or less extensively by the vesicular eruption. The surface sometimes moist, sometimes dry, rarely gives to the hand a sensation of febrile heat, although the temperature of the body ranges above the normal standard. The pulse from the outset is wanting in firmness, and the indications of
defective tone increase as the disease advances. The respiration exhibits no marked disturbance, excepting an increase of rapidity witnessed during accessions of pain and restlessness, and in the advanced stage of the malady the diminution dependent upon failing circulation and innervation. The alimentary canal, apart from the vomiting, which usually ceases as the disease becomes fully developed, presents little indication of disturbance. The tongue is as frequently clean and moist as dry, foul, and discoloured; and the bowels may be either costive or loose, the former, perhaps, more commonly than the latter. In some outbreaks, indeed, costiveness has been marked and almost general, but in others diarrhoea has been prevalent. The renal secretion is rarely much disturbed.

As the malady proceeds, if it tends towards a fatal termination, the spasmodic symptoms increase, the patient becomes comatose, and death may occur either from asphyxia or exhaustion in from ten or twelve hours to seven or eight days. If the disease is prolonged beyond this period, various secondary lesions are apt to occur, especially certain inflammatory states of the eyes and the ears, the mischief in the former organs being shown by ulceration of the cornea, iritis, and sometimes suppuration of the globe; in the latter by less obvious structural changes during life except as indicated by deafness. Or there may be paralysis affecting one half of the body, or one side of the face, or one of the limbs, or an isolated group of muscles. Or there may be an inflammatory state, with sero-purulent effusion into one or more of the large joints. Or, finally, the patient may fall into a state of marasmus and nervous exhaustion, often protracted and not rarely fatal. If the malady proceed to a favourable termination without any of these sequences, health may be recovered in from three to four weeks. If the progress of the disorder, otherwise favourable, is interrupted by one or other complication, the period of recovery is uncertain and often long postponed.

(b.) Fulminant Epidemic Cerebro-spinal Meningitis.—In the siderant form of the malady the onset is without premonition. The patient suddenly falls into a state of collapse. The surface of the body has often a cyanotic aspect, and is cold and clammy to the touch, or covered with a profuse perspiration, the face being not rarely shrunk and livid, and the eyes deep sunk as in the algide stage of cholera. There may be some shivering at intervals, more or less pain of the head, and occasional vomiting, sometimes of a grumous black or coffee-coloured fluid. Drowsiness, if not present at the outset, rapidly supervenes, followed by or concurrently with delirium. Coma, rarely other than the precursor of death, quickly succeeds. In the meantime, purpuric spots show themselves over the surface of the body generally, red or purple and circumscribed in the beginning, but rapidly becoming black, and often extending their margins so as to form irregular inky blotches, or streaks, or great patches; and not unfrequently several of the spots become gangrenous. Sometimes the purpuric spots appear contemporaneously with the collapse at the
outset of the attack. The respiration is preternaturally slow, and the pulse (if it has not been absent at the wrist from the beginning) falls with the progress of the disease. The urine is loaded with albumen. Life may be extinguished in less than five hours, or it may be prolonged for two or three days. Recovery from this form of epidemic cerebro-spinal meningitis is not unknown, but it is an exceedingly rare event.

(c.) Purpuric Epidemic Cerebro-spinal Meningitis.—In the purpuric form of epidemic cerebro-spinal meningitis, the symptoms which distinguish the simple and fulminant forms of the disease occur combined together in various proportions, some cases approximating more or less closely to the latter, others, as is most common, to the former variety of the affection. Thus concurrently with shivering, intense headache, vomiting, rachialgia and retraction of the head, there may be depression of the vital powers approaching collapse, or collapse itself, with the development of petechiae, purpurae, vibices, ecchymoses, haemorrhage from the mucous tracts, delirium, coma, and rapid dissolution. In far the greater number of cases, however, the disease follows the course of simple epidemic cerebro-spinal meningitis; but within twenty-four hours, or from this period to the fourth day, or still later in the progress of the malady, petechiae or purpurae are developed more or less copiously, and occasionally haemorrhage occurs from the mucous tracts. This phase of epidemic cerebro-spinal meningitis does not appear to be more fatal than the simple form of the disease. It has been observed more commonly in the United States than on the continent of Europe, and it was the principal variety which occurred during the recent outbreak in Ireland.

SPECIAL SYMPTOMS. — 1. The Nervous System. — Headache is almost constant, and it is remarkable for its early and persistent severity. At the outset it is not localised in any particular part of the head. It may be referred to the forehead, the sides, the vertex, or the occiput; or it may be general. Later in the disease, the occiput is, perhaps, most commonly the seat of pain. The intensity of the headache is, as a rule, peculiar. The patients describe the pain as sharp, lancinating, stabbing, plunging, tensive, throbbing, boring, or crushing. It is so intolerable as to elicit groans and cries from the sufferer; often even during delirium or stupor, the exclamations, the contraction of the forehead, and the manner in which the hands are moved towards the head, show that the pain continues. In young children this state closely resembles that which is so significant of tubercular meningitis. The headache may cease when the disease has become fully developed, or, as is probably more common, it may persist throughout the whole course of the malady so long as consciousness remains. Occasionally, indeed, when recovery takes place, it will continue far into the period of convalescence.

Rachialgia is rarely absent. It is sometimes general throughout the spinal region, but more frequently it is limited to the loins, the
dorsal region, or, as is most usual, to the posterior part of the neck. Occasionally the pain radiates from the neck to the extremities and walls of the abdominal and thoracic cavities. In rare cases the pain has commenced at some point of the peripheral nervous system, and spread thence to the back, occurring in paroxysms. This pain has the same character as the cephalalgia, and the words (intolerable, atrocious, tense, &c.) used to indicate the nature of the latter may be employed also to describe the former. It is augmented by movements, and its chief seat is in the muscles of the spinal column.

The nuchal pain and its consequences constitute one of the most characteristic signs of the disease. Frequently, at the outset of the malady, this pain is preceded by a dragging sensation at the back of the head. As the pain increases in intensity, the head is voluntarily thrown back to relieve all strain upon the exquisitely sensitive muscles. Or, in conjunction with the pain, spasm of the affected muscles occurs, and the head is forcibly drawn backwards. Among the popular terms of the disease, those arising from this symptom (Nackenstarre, Genickkrampf, Nacksjuka, &c.) are very prominent. When the rachialgia is more diffused, and the pain extends also to the limbs, adapted or spasmodic contractions of the trunk and lower extremities are apt to occur. Rachialgia is not present in the siderant and in severe cases of the purpuric forms of the affection. It is noteworthy that pressure on the spinous processes, during the most acute rachialgia, rarely causes pain.

Enteralgia and other Neuralgic Pains.—Abdominal pain, neuralgic in character, and more or less closely linked to the pain in the course of the spine, is not unfrequent, and it is often closely associated with uncontrollable vomiting. In some epidemics, as in that of 1865 on the Lower Vistula, enteralgia was so common among children seized with cerebro-spinal meningitis that it gave rise to the trivial designation "belly-ache," as one of the popular names of the disease. Neuralgic pains in the limbs, referred to in connexion with rachialgia, are less common than like pains along the course of the spine and in the abdomen.

Increased Sensitiveness of the Surface of the Body has been described as frequent in several outbreaks. During the recent epidemic in the United States, cutaneous hyperästhesia is said to have been a characteristic symptom of the disease in its fully developed state. During the outbreak on the Lower Vistula, an increase of cutaneous sensitiveness was also observed very commonly, but it was not regarded by Dr. Burdon Sanderson as a characteristic symptom, but "a mere consequence or interlude of pain;" being, in fact, an excessive tenderness experienced during intermissions, or after the cessation of pain.

Spasm.—Sufficient care has not always been taken to discriminate between apparent and actual spasm in this disease. Tourdes, in 1843, showed that the retraction of the head and curvature of the spine did not in all cases arise from a spasmodic contraction of the muscles, but that the position was not rarely voluntarily or instinc-
tively assumed by the patient as most conducive to relief of the spinal pain. Dr. Burdon Sanderson confirmed this observation of Tourles, so far as retraction of the head was concerned, in 1865. In the cases observed by him, in which the head was apparently drawn backwards, it was practicable to extend the seemingly contracted muscles, although the effort gave rise to exquisite pain and instinctive resistance. There was not any tension of the muscles except such as arose from this resistance; no tightness was felt so long as they were at rest. “It was not till the neck was completely extended that the muscles became hard, and even then the hardness was not for a moment comparable to that which is felt in tetanus.” The position in bed of the patients observed by Burdon Sanderson was that which would produce the greatest relaxation of painful groups of muscles. There can be no doubt, however, that spasm is a frequent accompaniment of epidemic cerebro-spinal meningitis. In the clonic form it is witnessed in some cases as transitory contractions of the facial muscles, cramps of the extremities, the convulsive agitation and trembling referred to in the general description as somewhat like what is observed in delirium tremens, very rarely in local convulsion of a single limb, and still more rarely in general convulsion. Tonic spasm of the muscles of the face, jaws (trismus), and gullet, and of the limbs and trunk, may also occur, giving rise to true opisthotonos, emprosthotonos, or general tetanic rigidity of the trunk and limbs.

Paralysis is not of very common occurrence during the progress of epidemic cerebro-spinal meningitis. Hemiplegia has been occasionally noticed, and paralysis more or less complete of one or both extremities, upper and lower, of the muscles of deglutition, of articulation, and of certain other associated groups, the latter chiefly towards the close of the malady. The general paralysis noticed by some writers was usually significant, and, indeed, a part of the phenomena of approaching dissolution.

The special senses do not often manifest much change, except as a consequence of certain structural lesions. Increased, sometimes exquisite, sensitiveness of sight and hearing has occasionally been noticed, concurrently with augmented sensitiveness to other external impressions, especially towards the close of the malady, when complete consciousness returns. Amaurosis has also occurred, without apparent change in the ocular apparatus. It may be noted, moreover, of the eye and sight, that occasionally there is strabismus and double-vision. The pupils may be normal in aspect and action, or they may present various changes. They may be dilated or contracted, or one dilated and the other contracted, or they may exhibit curious alternations of contraction and dilatation under the influence of the same degree of light. Both the eyes and the ears are liable to undergo certain structural lesions. These consist in well-marked inflammatory changes, commencing sometimes in the cornea, sometimes in the deeper tissues. Most commonly keratitis is set up, ending in opacity or ulceration; and if the latter, the iris may become
involved. Or, iritis may occur independently, with effusion of lymph or pus, and the consequences thereof (synechia posterior and distortion of the iris are particularly noted). Of more deeply-seated changes may be mentioned opacity of the lens or of the vitreous humour, separation of the retina from the choroid, purulent infiltration, or atrophy of the eyeball. The ear suffers, perhaps, more frequently than the eye. Deafness is probably more common than defects of vision, and it is largely dependent upon inflammatory changes set up in the organ, and particularly affecting the lining membrane of the vestibule and semicircular canals. Occasionally, the external meatus has been affected, and a profuse purulent discharge flowed from it. These lesions of the organs of sight and hearing may occur either early or late in the course of the disease. The sense of smell very rarely suffers. Its loss in one nostril has been recorded in a single case, and this, perhaps, dependent upon inflammatory changes in the lining membrane of the nose, as purulent discharge from the nostrils has occasionally taken place.

Vertigo is sometimes observed as an initial symptom of the disease in conjunction with the cephalalgia. Instances are recorded in which the first accession of the disease was marked by severe giddiness, during which the patient either staggered about like a drunken man, or turned round several times, and then fell.

Delirium is rarely absent. It varies much in character, and may occur at any period of the seizure. It may be quiet or violent, transitory or more or less persistent. It sometimes, but rarely, forms one of the symptoms of invasion, when its access is sudden and its character acute. It may supervene with violence after the malady has continued several hours or two or three days. In the acute form of delirium, the patient is very noisy, and often so violent as to require restraint. Sometimes it happens that paroxysms of furious excitement occur with intervals of placid delirium. Hence the necessity of great watchfulness in the care of these cases. Most commonly the delirium follows closely upon the initiatory symptoms, and is aggravated as the disease advances. At the beginning, the confusion of thought may not be so great but that the patient can be roused so as to answer questions intelligibly. Later, the incoherence becomes much greater, and is usually accompanied with considerable agitation. Much difference is observed, not only in the degree of impairment of the consciousness, but also in the periods of manifestation of the impairment. In some cases, the delirium occurs chiefly during the night; in others, and very commonly, it alternates with periods of somnolence or of quietude. In the more persistent cases there are usually exacerbations. If the disease tend to a fatal ending, the delirium is followed by coma; if to recovery, consciousness is, as a rule, gradually recovered; but, at times, a period of stupor intervenes between the subsidence of the delirium and returning perception. In the slightest cases of the malady the delirium may be transient only, taking place at intervals chiefly during the night. In the gravest cases, when death
occurs in a few hours, delirium is most commonly present. The duration of the delirium depends entirely upon the nature and duration of the case. Instances are recorded in which furious delirium has occurred for three nights in succession. In other instances a delirious state has persisted more or less continuously for fifteen days.

Stupor and Coma.—In not a few protracted cases, delirium is followed by a prolonged state of stupor, the patient lying completely indifferent to external impressions. In six cases observed by Dr. Burdon Sanderson, in which there had been violent delirium at the outset, this state lasted from one week to five weeks, the mean duration of the several cases being nineteen days. The observer remarks, however, that as four of the cases “emerged from their stupor in a state of complete deafness, there was much difficulty in limiting accurately the period of unconsciousness.” Sometimes the state of stupor supervenes without the intervention of violent delirium. Coma occurs in nearly all fatal cases, and is, indeed, generally the forerunner of death.

2. The Digestive System.—The uncontrollable vomiting, which is one of the characteristic initiatory symptoms of the disorder, is an effect of the cerebral mischief. Most frequent at the beginning of the malady, the vomiting diminishes as the disease advances, occasionally increasing during exacerbations. The matter evacuated, after the stomach has been emptied of food, is usually of a greenish or yellowish colour and bitter taste, and is composed largely of bile; more rarely it is viscid and white. Occasionally, in the fulminating and purpuric forms of the malady, a grumous black or coffee-coloured fluid is vomited. In several outbreaks, the vomiting of large quantities of Ascarides lumbricoides has been specially noted. The buccal cavity and tongue do not exhibit any particular signs, except in those rare cases in which there is hæmorrhage from the gums. As a rule, the tongue is clean and natural at the outset, and its subsequent state depends upon the degree of febrile excitement which may be set up, or the development of a typhous state, when it may become foul with various well-known aspects, or dry and black sordes accumulating on the teeth. From the beginning of the attack the appetite for food is destroyed, whatever the state of the buccal cavity; and sometimes there is much, at others insatiable, thirst. The bowels are more commonly costive than the reverse. In some outbreaks costiveness has been of general occurrence. Diarrhoea, late in the disease, is not unfrequently to be attributed to the previous administration of purgatives, and involuntary stools are usually one of the accompaniments of complete nervous and vital prostration.

3. The Urinary System.—In the simple form of epidemic cerebrospinal meningitis the urine does not exhibit any marked change. It may be more abundant, and slight deposits of lithic acid may occur. In the fulminating, and severe cases of the purpuric forms, it commonly (in the first-named form perhaps invariably) contains albumen, sometimes in large amount, and occasionally cylindrical casts and blood-
corpuscles. Retention or incontinence of urine has occurred in the progress of the disease.

4. The Respiratory System.—In all the graver cases the respiration is more or less altered. It is sighing, laboured, or interrupted. Dr. Burdon Sanderson writes of the outbreak on the Lower Vistula: "In all severe cases, whether of children or adults, the breathing was embarrass'd in proportion to the general gravity of the symptoms. This embarrassment was marked by a slow laboured inspiration, followed by quick respiration and a long pause,—that condition of breathing which is so frequently observed in continued fever (especially typhoid), and is often called suspicios. In all the fatal cases which came under my notice, the most prominent symptoms which preceded death were those which indicate impairment and perversian of the respiratory function. As the breathing became more hurried and difficult, the general depression became more intense, the pulse became weaker and quicker, and the temperature of the skin more elevated." Dr. S. Gordon records a case, fatal in less than five hours, in which the respirations rapidly fell to nine per minute, the pulse at the time being 120.

5. The Circulatory System.—The cardinal point with respect to the circulation, as indicated by the radial pulse, is defect of arterial tension. This has been common to all epidemics, with hardly an exception; and the exceptional instances have probably been more apparent than real. The frequency of the pulse does not admit of general statement. It has a wide range. In the epidemic on the Lower Vistula, the pulse in six adult cases observed by Dr. Burdon Sanderson varied from 56 to 98, the average beats being 85. In several cases noted by the same observer "its frequency varied considerably from day to day, without apparent relation to the condition of the patient in other respects." During the Philadelphia outbreak of 1866, in 98 cases observed by Mr. W. H. H. Githens, the pulse varied from the normal beat to 150 per minute in uncomplicated cases, and reached as high as 160 in two cases, in puerperal women. "It was in all very weak, with a dichrotic tendency, sometimes entirely imperceptible in the radial artery, and always interrupted by slight pressure."

6. The Cutaneous System.—In respect of dryness or moisture or feeling to the touch, the skin presents no constant condition; but, in numerous cases, it is the seat of various forms of eruption of remarkable interest. The extent of prevalence or predominance of one or other of these different forms of eruption has varied considerably in the numerous recorded outbreaks. In the epidemics which have occurred in the United States, petechia have been so common as to have given rise to the popular name of the disease (spotted fever), and to have induced Dr. G. B. Wood, Professor of the Theory and Practice of Medicine in the University of Pennsylvania, to adopt as the technical designation of the disease the term petechial fever. During the recent outbreak in Ireland (1866-67), purpura was the predominant form of eruption, and Professor Stokes proposed to
designate the malady *malignant purpuric fever*; other observers also suggesting terms founded upon this character. In the outbreak on the Lower Vistula (1865), an herpetic eruption was most common. In all the greater outbreaks, each form of eruption mentioned in the definition of the disease has been observed; but the proportion of cases in which one or other form of eruption has prevailed has varied greatly in each outbreak. In some of the earlier outbreaks in the United States few cases occurred in which a petechial eruption was not noted. Of 98 cases admitted into the Philadelphia Hospital (Blockley) in 1866, 36 had petechiae; 13 mixed petechie and erythema; 9 erythema and urticaria; 3 indistinct petechial mottling; and 37 no eruption at all (Githens). In the outbreak on the Lower Vistula the proportion of cases exhibiting an eruption was comparatively small; in the recent outbreak in Ireland, large. The forms of eruption observed are as follows:—(a) *Vesicles*. A vesicular eruption (*eczema, Hirsch*), sometimes herpetic in character, chiefly appearing in the vicinity of the lips, but occasionally extending over the sides of the face, diffused more or less on the trunk, or showing itself in patches on the limbs. This symptom has occasionally taken the form of shingles. It is most commonly noticed in the simple form of the disease, but it may take place in either of the other forms, and when associated with purpura, the vesicles may be flattened and rest upon a livid base, presenting a horrible aspect. This form of eruption may appear as early as the second day. (b) *Purpura*. 1. True *petechiae*. 2. *Purpuric spots*, varying in size from a split pea to half-a-crown, with more or less extensive effusions of blood, or of its colouring matter, into the cutis (*ecchymoses*). The spots have sometimes a regular, sometimes an irregular, even a ragged, outline. Their size may remain fixed from the time of their first appearance, or it may increase largely and rapidly. They may be of a light or dark red colour at the outset, subsequently becoming purple and black; or, as is most common, they may from the beginning be dark purple or black, their blackness being often fittingly likened to that of ink—the eruption resembling "spots" or "splashes" of that fluid. They may appear on the trunk or limbs only, or they may be scattered copiously over the whole surface of the body, including the face. The purpuric spots are frequently hard to the touch, the margin being defined, and giving the impression to the fingers of being raised above the surface: sometimes a vesicle forms above several of the spots, and gangrene of the adjacent tissue takes place. Dr. S. Gordon writes of the recent epidemic in Ireland: "Many cases are accompanied by a distinct eruption, which comes out with great rapidity; is found over all parts of the body, but chiefly on the lower extremities; is of a very dark colour, sometimes very deep brown, or purple, or even black. The spots are of various sizes and shapes, some small and round, others large and irregular; some appear like large spots of very black purpura, only more mottled and more irregular in colour and shape; others are more confined, and raised above the level of the skin, consisting in effusion into its substance: many patients die in
this stage, but in some the disease progresses, and these spots are
absorbed, leaving a yellowish mark under the cuticle; or they pass into
superficial gangrene, which was spreading at the time of the patient's
death, or is healed with loss of substance. Purpuric spots are some-
times, although rarely, one of the earliest signs of the fulminant and
purpuric forms of the malady; or they may occur at any period during
the more advanced stages. Usually they appear at some period during
the first four days, chiefly perhaps during the first or second day.
Sometimes, with or without the purpuric spots, there is a cyanosed
aspect of the skin, or a peculiar livid mottling. During recovery the
purpuric spots gradually lose their definition and fade away, passing
through the different stages of colour which mark a healing bruise.
(c) Roseola, erythema, &c. Rose-coloured spots or patches are
occasionally observed; also erythema, more or less diffused, a rubeoloid
eruption, and urticaria.

7. Temperature.—The temperature of the body, as marked in the ax-
illa, is heightened in every case; except, perhaps, those accompanied by
profound collapse from the beginning. In many cases this heightened
temperature is found contemporaneously with the invasion of the dis-
ease; in other cases there is no conspicuous increment until the second
or third day. When the characteristic symptoms of the malady are
developed, the temperature rarely falls below 100° Fahr., and, as
the disease advances, it ranges in adults from 100° to 105°, in
children sometimes even higher. There is no constant or conspicuous
difference between the morning and evening temperature, as in typhus
and typhoid. A steady fall marks the decline of the disease and the
approach of recovery; a rapid fall ushers in collapse or death.

Complications.—The course of the disease is liable to be modi-
fied by certain complications. Of these the chief are as follow:—
(a) Thoracic inflammations: pleurisy, pneumonia, bronchitis, or peri-
carditis. Dr. S. Gordon describes oedema of the lung and diffuse
pulmonary apoplexy. (b) Swelling or inflammation of the parotids.
(c) Inflammation of the large joints, marked by swelling and pain,
and sometimes ending in sero-purulent effusion. This complication, in
its less aggravated form, has been described by some writers as rheu-
matic. (d) An inflammatory condition of the eyes and ears, as already
noted. (e) Bed-sores. Large, deep, black sloughs occurred in four
cases out of 161 treated in the Philadelphia Hospital in 1866. (f) The
course of the disease has also been complicated by the supervision of
other maladies, namely, (1) Intermittent fever, or certain paroxysmal
phenomena simulating malarious poisoning: a complication which
has led to erroneous notions of the nature of the disease. In the
outbreak on the Lower Vistula cases were observed in which regular
or irregular intermissions took place that could not be assigned to
a malarious origin. (2) Typhoid fever, the two diseases prevailing
simultaneously in the same district. The symptoms of both diseases,
more or less modified, pursue their course together, and the charac-
teristic lessons of typhoid as well as of epidemic cerebro-spinal meningitis are discovered after death. (3) Measles and scarlet fever. (4) Cholera (Levy).

**Duration.**—In the outbreak on the Lower Vistula, the most acute cases terminated fatally in from 12 to 72 hours. Cases of less intensity, but in which the patient eventually died in a typhous state, lived from 8 to 14 days, the characteristic symptoms of the disease persisting to the end. In the more protracted, or complicated cases, from 5 to 8 weeks have passed before a patient entered upon convalescence, and death has taken place in the 6th or 7th week. Of the cases observed in the Philadelphia Hospital (1866), the duration of those which ended fatally was from 48 hours to 14 days; of those which recovered, from 20 to 30 days, the acute symptoms rarely exceeding a fortnight. In the recent outbreak in Ireland, Dr. S. Gordon has reported a well-marked case which ended fatally after less than five hours' duration. A large proportion of the fatal cases in that outbreak died in from 10 to 48 hours; in other cases the fatal ending did not occur until the end of the second and during the course of the third week of the disease. The duration of the disease, as shown by death, may be clearly stated; as marked by the beginning of convalescence, it does not admit of definite description. Moreover, convalescence is often very protracted. The course of the disease towards recovery is sometimes interrupted by relapses.

**Termination.**—The disease terminates after a longer or shorter period of convalescence in health; or it entails during convalescence a series of physical or mental ills; or it ends in death. The rate of mortality of the disease is the measure of probable recovery. It varies much in different outbreaks, but is at all times formidable. Among the cases observed in the Philadelphia Hospital in 1866 the mortality was 33 per cent.; in the Hardwicke Hospital, Dublin, the same year, the mortality was 80 per cent. Dr. Stillé remarks that, "while ten epidemics in various places, occurring between 1838 and 1848, presented an average mortality of 70 per cent., a similar number occurring during the decade from 1855 to 1865 give an average mortality of about 30 per cent. This remarkable fact would seem to indicate a gradual decline of power in the epidemic." The minimum rate of mortality recorded is 20 per cent. The proportion of fatal cases is greatest, and the duration of these cases least, at the commencement of an outbreak. The sequelae which interfere with the restoration of the patient to perfect health are:—Deafness; impaired vision from structural changes in one or both eyes; paralysis of one or more limbs or of certain groups of muscles; impaired memory; carbuncles, and boils. Dr. S. Gordon describes a case in which the patient "recovered from all the acute symptoms, but gradually passed into a state of almost organic life. He ate, drank, and slept well; he passed solid faeces and urine without giving any notice, yet, evidently, not uncon-
Epidemic Cerebro-Spinal Meningitis.

He was excessively emaciated, and there was a peculiar mouse-like smell from him; he seemed to understand what was said to him, but he could not answer; he never called for anything; his breathing was rather slow; his pulse, 120; his heart acting with a peculiar strong jerking motion; his eye was quite well, as also his knee [he had suffered from ulceration of the right cornea and immense effusion into the right knee-joint]; he could draw his legs and arms up to him; but he could not use his hands at all." Such was the condition of the patient fifty-eight days after the invasion of the disease.

Mode of Death.—Death chiefly occurs from (a) asphyxia, caused by damage to the respiratory nerve centres; (b) from asthenia; and (c) in some of the fulminating cases probably from necrosis, so profound are the changes observed in the blood.

Diagnosis.—In some instances the disease approximates in certain symptoms to typhus or typhoid, and it occasionally prevails contemporaneously with both maladies. But the history of the development and progress of the disease, with the absence of characteristic eruption, will usually clear up any doubt. From sporadic spinal meningitis the disease is distinguished by its epidemicity, the almost constant concurrence of cerebral disorder, the tendency to cutaneous eruptions, the great mortality, and the rareness of protracted or permanent paralysis or contraction of the lower limbs. The distinction between the disease and cerebral meningitis is less defined as to particular symptoms, especially in children, but the mode of development of the malady will rarely leave much room for doubt during an outbreak. Tetanus (so-called idiopathic), with which it is suggested that epidemic cerebro-spinal meningitis may, under certain states of spasm, be confounded, never manifests the early grave cerebral symptoms which occur in the latter disease. The tetanoid contraction also observed in epidemic cerebro-spinal meningitis is rarely, if ever, as in tetanus, aggravated by sudden and painful spasms. The grouping of the symptoms in the two diseases is, moreover, altogether different. Dr. S. Gordon points out the possibility of confounding the purpuric form of epidemic cerebro-spinal meningitis with malignant measles, which malady has often prevailed at the same time. The last-named disease may resemble the fulminating form of the first-named in several respects, particularly the rapidity of development, and dark colour of the eruption, and the rapid appearance of petechiae; also in the sudden and often extreme collapse which accompanies the invasion of the affection. But the eruption of measles rarely loses its characteristic form, and the affection of the respiratory passages is commonly present, while purpuric spots and patches are seldom observed. Dr. S. Gordon also states that he has known several cases in which the earlier symptoms of epidemic cerebro-spinal meningitis in young excitable females have been mistaken for hysteria.
Prognosis.—At the best, the prognosis of the disease is very grave. The mortality may be equally great in each of the three varieties, and petechiae and purpura do not necessarily indicate an aggravated degree of danger as in other acute diseases. In 50 per cent. of the cases recorded by Dr. Githens, in one of the least fatal outbreaks known, petechiae were present, and it is especially remarked that neither this nor any other form of eruption had "any reference to the prognosis." But when haemorrhage into the cutis is extensive, either from the number or the size of the spots, and is accompanied by marked signs of vital prostration, it indicates an extremity of danger, although not a certainty of death. The disease is more fatal among infants and young children than among youths and adults in the prime of life; but, in some outbreaks, the latter have suffered most. After thirty years of age it becomes more dangerous. Life is most endangered in the earlier days of the disease, particularly during the first five. But danger is present at all periods of the malady, and the convalescent is not entirely safe until health is fully restored. Of the special symptoms, whether of excitement or depression, the rules of prognosis hold good which apply to other highly fatal acute maladies.

Morbid Anatomy.—The essential anatomical characteristics of the disease, found after death, are hyperæmia, often intense, of the pia mater of the brain and spinal cord; with more or less copious sub-arachnoid, and interstitial effusion into the meshes of the congested pia mater, either of serum, or of a transparent, gelatinous material, or of purulent matter: the latter more frequently than either of the two former. The purulent effusion is of greenish or yellowish colour, and is sometimes flaky. It has been found in a case in which death took place in less than five hours from the invasion of the disease (S. Gordon). The extent to which these appearances are observed and the amount of effusion varies greatly in different cases. No part of the encephalic or spinal pia mater and arachnoid may be free, or certain portions alone may be affected; but effusion is limited to the sub-arachnoid space, and does not occur into the arachnoid cavity. Under the microscope, according to Dr. Burdon Sanderson, the gelatinous material is "always found to consist of cell-like bodies, either adhering to each other so closely that they could not be completely separated, or imbedded in a transparent interstitial substance, while the sero-purulent liquid which occupied the spinal sub-arachnoid space, and in some cases the ventricles, exhibited corpuscles and granules floating freely. The cell-like bodies, although in general resembling pus corpuscles, did not present that uniformity of size and character which is met with in normal pus. They were usually, but not always, of regular circular contour, and varied in diameter from $\frac{3}{4}$ of a inch. Occasionally they exhibited the appearance of an external cell-membrane, but in most instances this could not be made out even in perfectly fresh exudations—as, e.g. in those cases which were
examined as early as eight hours after death. They invariably con-
tained numerous granules, some of which were cleared away on the
addition of acetic acid. Those which remained were highly refrac-
tive, but did not assume any special form of arrangement. The
interstitial substance was beset with granules, some of which were
albuminous, others fatty. It was most abundant and distinct on the
surface of the spinal arachnoid, where it infiltrated the fine connecting
tissue and minute blood-vessels of the pia mater."

For the rest, the nervous system of the brain and spinal cord is
usually gorged with blood, except death has taken place late in the
course of the disease. The visceral arachnoid is frequently thickened
and opaque. Softening of some portion of the spinal cord has some-
times been observed; and Mr. J. Simon thinks that, "for practical
purposes, the state of the covering membranes of the nervous centres
may be regarded as a mere index of changes more or less distinctive,
which those centres in their own intimate composition have at the
same time undergone; and hence it is that the essential phenomena
of the disease during life consist in disturbances, more or less grave,
of the functions of these all-important organs."

In fatal cases of the simple and purpuric forms of epidemic cerebro-
spinal meningitis the characteristic anatomical lesions are almost
invariably found. In the fulminating form of the disease they are
often absent. The cases in which there is no indication of morbid
change in the nervous centres are exceedingly few. It has been
suggested that in these cases death has occurred so rapidly that there
was insufficient time for the formation of a structural lesion. In
connexion with this explanation the case recorded by Dr. S. Gordon
must be borne in mind, in which purulent effusion was found,
although the whole duration of the attack was under five hours.
Practically the apparent absence of characteristic anatomical change
in the nervous centres in certain rare cases of epidemic cerebro-spinal
meningitis is a phenomenon analogous to that which sometimes
occurs in rapidly fatal cases of malarious, variolous, and scarlatinous
poisoning, in which the characteristic eruptions or lesions of the
diseases have not been developed.

No lesions peculiar to epidemic cerebro-spinal meningitis are found
in other organs of the body. Such lesions as occur elsewhere than
in the coverings of the brain and spinal cord usually have a definite
relation to the thoracic, abdominal, or genito-urinary complications
which may have happened during the progress of the malady. In the
fatal cases of the purpuric form of the affection recorded by Dr. S.
Gordon, and other writers, an excessive fluidity of the blood was noted.

**History and Geographical Distribution.** — The history of
epidemic cerebro-spinal meningitis dates only from the fourth
decennium of the present century. At that period the disease was,
for the first time, clearly distinguished as an independent malady;
and with the light then obtained, outbreaks which had occurred
earlier in the century, in various localities of both the Eastern and Western hemispheres, and had been recorded under other names, were recognised as of a similar character. It has been sought, indeed, to show that epidemic cerebro-spinal meningitis has probably existed from remote periods (TOURDES, BOUDIN). The probability may be admitted, for the first recognition of a malady as an independent affection does not necessarily imply that the malady is new.

In 1837 epidemic cerebro-spinal meningitis broke out in the south-west of France, and prevailed in various localities of the district intervening between Bayonne and La Rochelle, and along the whole line of the Pyrenean frontier. Dax, Bordeaux, Auch, Foix, Narboune, and Perpignan suffered, as well as the two cities previously named. The disease, according to Boudin, at the commencement and during the continuance of this outbreak, chiefly showed itself among troops in garrison. During 1837 and 1838 the garrisons of Bayonne, Dax, Bordeaux, Rochefort, and La Rochelle suffered. From 1838 to 1841 the disease was prevalent among the garrisons of south-eastern France, particularly those of the valley of the Rhone. Thus it broke out at Toulon, Marseilles, Aigues-Mortes, Nîmes, Avignon, and Pont-Saint-Esprit. In the course of the four years, 1839-40-41-42, the malady appeared in succession among the troops occupying the fortresses of Strasbourg, Schelestadt, Colmar, Nancy, Metz, and Givet. From 1839 to 1842 it prevailed among the forces at Versailles, Saint-Cloud, Rambouillet, and Chartres. Those stationed along the coast of Brittany, at Brest, L'Orient, Nantes, and Ancenis, suffered in 1841; and during 1840 and 1841 the disease manifested itself among divers detachments of a regiment scattered at Laval, Le Mans, Chateau-Gontier, Tours, and Poitiers. It was during the outbreak of which the most remarkable episode is thus sketched by Boudin that a scientific knowledge of epidemic cerebro-spinal meningitis was first obtained. From 1837 to 1848 inclusive, forty-seven outbreaks of the malady were recorded in thirty-six of the eighty-six departments into which France was then divided. These outbreaks were distributed in the departments of the Loire, Rhone, Bouches-du-Rhone, Bas-Rhin, Seine, Seine-et-Oise, Landes, Basses-Pyrénées, Charente-Inférieure, Gard, Vaucluse, Var, Moselle, and Lorraine. The three first-named departments suffered most. In 1840, the disease appeared in Naples and prevailed in the Papal States. The same year it broke out among the French garrison at Douera, Algeria, and during the next seven years it attacked numerous towns and localities of the province, affecting the civil population, both European and native, as well as the military. In 1844 an outbreak of the disease took place among the civil population of Gibraltar; and in 1846 the malady showed itself slightly in Ireland among the inmates of the Rathdown, South Dublin, and Belfast workhouses, and several cases occurred among the population of Dublin. During 1849 and 1850 the disease was prevalent to some extent among the French troops in Italy, and in the last named year several localities of France suffered from it.
Epidemic cerebro-spinal meningitis appeared in Denmark in 1841, and prevailed in that country until 1848. The disease was first noticed in Sweden in 1854, this country again suffering from it in 1861. In Norway the malady broke out in 1859, and it has prevailed in that country more or less since that year. During 1860 the disease was prevalent in Holland; and the same year it was widely spread in Portugal. In 1863, 1864, and 1865 an extensive outbreak occurred in North Germany; and in 1866 the malady broke out in Dublin and elsewhere in Ireland.

In the United States (where the disease may be traced back to the commencement of the century), epidemic cerebro-spinal meningitis became prevalent about the same time that it exhibited great activity in Europe. From 1842 to 1850 inclusive, a series of outbreaks took place in the States of Kentucky, Tennessee, South Illinois, Mississippi, Arkansas, Alabama, Pennsylvania, Massachusetts, New York, and North Carolina. After this period there would appear to have been an interval of comparative inactivity. In 1861 the disease broke out in North and Central Missouri, and from that time to the present it has prevailed, more or less extensively, in almost all, if not all, the States of the Union, with the exception, perhaps, of the Pacific States. In 1862 outbreaks were recorded in Connecticut, Kentucky, Indiana, and Tennessee; in 1863, in Rhode Island; in 1864, in Pennsylvania, Ohio, Illinois, New York, Maryland, Massachusetts, and Vermont; and in 1865 in North Carolina and other Southern States. During the past year the disease was active in several States.

It must be borne in mind that these historical notes very imperfectly represent the probable prevalence and geographical distribution of the disease. They simply include a brief summary of outbreaks which have come under the notice of thoughtful observers who have published their observations. The history of the malady in the British Islands is, perhaps, less liable to error from this source. The earliest recorded outbreak of the disease occurred in Ireland during the early months of 1846. It broke out to a very limited extent among the boys living in the Rathdown Union, South Dublin, and Belfast workhouses; and two cases, both females, one aged 17 years, the other 36 years, were admitted into the Hardwicke Hospital, Dublin.* Prior to this outbreak, there is not any trustworthy history of the presence of epidemic cerebro-spinal meningitis in the British Islands. It is not improbable, however, that the disease existed at Blackaton, in Devonshire, in 1807;† and at Sunderland in 1830.‡ Dr. B. W. Richardson saw an unquestionable case at Mortlake, Surrey, in 1843.§ From the time of the outbreak in 1846, cases of a similar malady were occasionally observed in Dublin, until the latter half of 1850, when they became more common.|| There is

† Mr. Henry Gervis, Medico-Chirurgical Society's Transactions, vol. ii.

no further notice of epidemic cerebro-spinal meningitis in Ireland until the year 1865, when cases began to be again observed in Dublin.* A case of cerebro-spinal meningitis was observed by Dr. Samuel Wilks, in each of the three years 1856, 1858, 1859, in the metropolis. † In October 1859, a fatal case of cerebro-spinal disorder, with petechial eruption, came under the notice of Dr. Heury Day, in the vicinity of Stafford. In this case, hyperæmia of the meninges of the brain and spinal cord, and copious effusion of fluid at the base of the brain, were discovered after death. A similar but more rapidly fatal case was also observed by Dr. Day, in the Stafford General Infirmary in September 1865. ‡ The largest and most fatal outbreak of epidemic cerebro-spinal meningitis which has occurred within the limits of the United Kingdom began in Ireland in March 1866, and attained its chief development in the subsequent winter. Its effects were almost entirely limited to the sister island, and the brunt of the outbreak fell upon Dublin. Other localities affected were Tullamore, Parsonstown, Mitchelstown, Thurles, Clondalkin, and the Curragh camp. The cases were not very numerous in Dublin; and in the country towns they were comparatively few. It is noteworthy that, as in the earlier outbreaks in France, the military in Ireland, in proportion to their strength, suffered prominently from the disease. In some of the country districts cases were recorded among the troops alone, or among persons in immediate connexion with them. § In January and February 1867, an outbreak of a disease characterised by severe rigors, tetanic convulsions, intense neuralgic pain in the head and upper part of the trunk, increased sensitiveness of the surface, obstinate vomiting, restlessness, and, in one instance at least, by a dark purple eruption, but of which not a single case died, took place at Bardney, in Lincolnshire, a village about ten miles east of Lincoln, on the verge of a fen country, and having a population of 1500, the bulk of whom are engaged in agricultural pursuits. ‖ Two cases of epidemic cerebro-spinal meningitis were recorded in London in the summer of 1867. One, a case of the fulminant form of the malady, in which death occurred in twenty-seven hours, took place in June; ‖‖ the other, a case of the purpuric form, in which death occurred in seven days, took place in July. **

The peculiarity of distribution of the disease in the British Islands, its epidemic manifestation being limited to one portion of the kingdom, and chiefly, even in recurrent outbreaks, to a small section of the population of that portion, is not an isolated phenomenon. Not-

withstanding the wide geographical prevalence of the malady as shown by the foregoing details, it must not be concluded that this prevalence represents a general diffusion of the disease among the different populations during the periods of its activity. The outbreaks of epidemic cerebro-spinal meningitis, as a rule, are limited to small sections of a population, and its distribution is by a series of isolated outbreaks, rather than by extensive spreading. This was shown remarkably, as already described, during the outbreak in France in 1837 and following years, when the ravages of the malady were principally confined to certain garrisons, and even to small sections of a garrison, without affecting the surrounding population. A like limitation of the disease to certain detachments of troops was observed during the recent war in the United States; and the restriction of the malady to small portions of workhouse populations, as in the first outbreak in Ireland, is an analogous phenomenon. Perhaps the sole outbreak in which an extensive diffusion of the disease among a community has occurred was that in the province of Dantzig, in 1864-65. The tendency to reproduction in a locality, as in Dublin, was particularly observed during the great outbreak in France from 1838 to 1848, when the disease reappeared again and again among the forces in Bayonne, Versailles, and Avignon, notwithstanding changes of garrison. The freedom of England and Scotland from outbreaks of so widely spread a malady is very remarkable; particularly if the seeming occasional cases of the disease to which reference has been made are to be regarded as true examples.

Etiology.—(a) Predisposing Causes.—Age. The personal liability to the disease is not governed in any definite manner by age. In some epidemics children, in others young people, in others again adults of from thirty to fifty years, have suffered in greatest proportion.—Sex. Generally, and in some outbreaks very markedly, males are more liable to the disease than females.—Profession. During the outbreaks of the disease in France from 1837 to 1849, a peculiar proclivity to the disease was observed among soldiers. But in subsequent outbreaks in France, and wider-spread outbreaks elsewhere, no special liability to the disease was manifested among any vocation.—Climate and Seasons. In the Eastern hemisphere our knowledge of the disease is limited to Western and Central Europe and Algeria, the northern boundary of the district not passing beyond lat. 61° N., the southern not beyond lat. 35° N.—the one extreme closely approaching the arctic, the other the torrid zone. In the Western hemisphere the records of the malady are confined to the populous districts of the eastern division of the United States, from lat. 30° N. to lat. 48° N. It is noteworthy that the northern and southern limits of distribution in both hemispheres but slightly overlap the isothermal lines 5° and 20°. Season acts as an unquestionable and powerful predisposing cause of epidemic cerebro-spinal meningitis, which is especially a disease of the cold months. Of 216 local outbreaks in France and the United States, 166 prevailed
between December 1st and May 31st; 50 in the other six months of the year. In Sweden, of 417 local outbreaks, 311 took place in the former period of the year, 106 in the latter (Stille). During the recent outbreak in Ireland, the brunt of the disease fell between January and July 1867. Of 85 outbreaks in various parts of Europe and the United States, noted by Hirsch, 33 prevailed in winter, 24 in winter and spring, 11 in spring, 1 in spring and summer, 2 in summer, 1 in summer and autumn, 1 in autumn, 1 in autumn and winter, 3 in autumn, winter, and spring, and 6 prevailed throughout the whole year.—Locality and soil do not exercise any manifest influence over the disease. It has been observed on low grounds, highlands, and on soils of the most various character indifferently.—Sanitary conditions. No definite relation exists between the sanitary state of habitations and of individuals and the occurrence of the disease. It has prevailed in some epidemics as well among the affluent as the impoverished—among those who are well-fed, well-housed, and well-clothed, as among those who are ill-fed, ill-housed, and insufficiently clothed. In certain outbreaks, as in that on the Lower Vistula, the prosperous classes suffered to a much less extent from the malady than the poor and miserable who were subjected to privation and much foulness of persons, dwellings, and atmosphere.

(b) Exciting Causes.—Fatigue has been mentioned as an exciting cause. In some of the early outbreaks of the disease among French troops, France being at war at the time, fatigue apparently exercised a determining influence. Again, during the recent outbreak in Ireland, the malady appeared very early among a “flying column” of troops occupied in the suppression of the Fenian disturbance, and exposed to great fatigue and inclemency of weather. But fatigue has played little or no part in determining the disease among the civil population, especially among children and the inmates of workhouses and prisons.—Cold. The marked predominance of the disease in the winter and spring months has suggested a causal connexion with cold. Hirsch has submitted the question to a detailed examination, and with this result: that, although the suspicion cannot be excluded that the temperature of winter and spring may have some direct effect upon the genesis of the disease, “the modifications in the mode of living incidental to these seasons exert, in a far higher degree, an influence favourable to the presence of this as of many other infectious maladies.”

—Certain Insanitary States. There is not any constant or even common relationship between any insanitary state and the appearance of the disease. Neither foulness of house and its surroundings, nor of the atmosphere, whether from putrid emanations or from overcrowding, nor impurity of any other kind, has any determinate relation with epidemic cerebro-spinal meningitis. But Hirsch remarks† of the outbreak in the province of Dantzig in 1865, that “the disease prevailed exactly in that season of the year in which, on account of inclement weather,

† Ibid. vol. ii. p. 372.
many individuals were crowded together into small and dirty rooms kept constantly closed by their occupants, and from which all ventilation was excluded, and in which the before-mentioned unfavourable hygienic conditions [dampness, great filth, and an atmosphere loaded with putrid emanations] were extremely perceptible." The causes here suggested have been held to be not altogether inoperative in other and more circumscribed outbreaks.—*Communication of the sick with the well.* The great majority of observers have come to the conclusion that the disease is incommunicable from the sick to the well. Among the minority who hesitate to accept this deduction without reservation are Professor Hirsch, Professor Stokes, and Mr. J. Simon. The facts which suggest the possibility of the active cause of the disease being portable in some way are of the following character:—(a) A child was seized with epidemic cerebro-spinal meningitis, and died. A second child of the same family was attacked with the malady a few days later. The day following the attack of this child, the mother, who slept in the same bed with it, sickened of the disease.* (b) 1. On the 8th February, 1865, a youth, aged 20 years, was attacked with the characteristic symptoms of epidemic cerebro-spinal meningitis. He was nursed by a woman from another village. The youth died, and after his death the woman returned home. She soon sickened, and she died of the epidemic disease on the 26th February. There had been but one case previously in the village. To the interment of the woman, the funeral obsequies, as customary in the district, being performed with the coffin open, came a family from another locality. After the return home of this family, a child, three months old, sickened immediately of meningitis and died within twenty-four hours. Then a man who had accompanied the family to the interment was attacked with the disease, and died on the 2nd of March. Lastly a girl, in the same locality, who had also been at the funeral, was seized, and died on the 7th March. 2. At another village, two children of one family, aged three and a half and one and a half years respectively, died of the epidemic, one on the 27th January, the other on the 7th February. The clothes of the deceased were taken to a neighbouring village, and came into the possession of a girl aged five years. She soon sickened of the epidemic, and died on the 14th February.† (c) Boudin relates instances of the appearance of the disease in garrisons, and among the civil population of towns, after the introduction of detachments of troops among whom the disease had prevailed or was prevailing at the time.

The foregoing facts simply suggest the possibility of the active cause of epidemic cerebro-spinal meningitis being communicable by the sick to the well. This possibility, notwithstanding the apparent formidable array of facts to the contrary, is not to be lightly dealt with. The lesson taught by the difficulties and doubts which beset the discovery of the communicability of typhoid fever and of cholera will have been

strangely misunderstood if it is necessary to urge upon observers the
importance of keeping the question of the possible communicability
of epidemic cerebro-spinal meningitis constantly before the mind. In
the consideration of this question, however, a caution is needed. The
term "contagion" is used too indiscriminately. It has been so long
employed to express the manner of transmission of disease which is
witnessed in small-pox, scarlet fever, or typhus, that it is difficult to
dissociate the idea of this manner from the word. It is almost impos-
sible, in reading the opinions of those writers who have come to the
conclusion that epidemic cerebro-spinal meningitis is not a "contagious"
disease, to avoid the suspicion, from their use of the adjective, that
they have looked upon the question too exclusively from the point of
view suggested by the diseases named. It is obvious that contagious-
ness of a like character to that of small-pox, scarlet fever, or typhus,
is not possessed by the malady under consideration. The question
is: Does epidemic meningitis, like typhoid fever or cholera, possess
a peculiar contagiousness of its own, a property of communicability
peculiar to itself? This has yet to be solved. Another explanation
of the facts which appear to indicate a possible communicability of
the disease from the sick to the well is, however, open, and is set
forth in the next paragraph.

_Diseased grain._—Dr. B. W. Richardson has suggested that epidemic
cerebro-spinal meningitis may possibly arise from the consumption of
diseased grain, after the manner of ergotism, and perhaps acrodynia.
He thinks that the probabilities are altogether in favour of the sug-
gestion, that "the cause, in fact, is a diseased grain, or fungus, con-
tained in some kinds of flour out of which the bread-stuffs are made.
This fungus may not be present in large quantities, and many persons
may eat of the food without getting a poisonous part; but one will
get it out of a number, and this without any communication beyond
the breaking of bread together: the disease may occur in one member
of a family, leaving the rest free, and in this irregular way it may be
distributed, in an epidemic form, over a large surface of country." He
adds, "If my hypothesis, as regards cause, be correct, there is little
danger of the disorder extending widely in this country; for of our
cereals used as food, nearly the whole of the population now select
wheat, and our wheat generally is selected for the market with great
judgment and circumspection. Any cases, therefore, that might occur
would be isolated, and would be easily traced out and prevented." *
This suggestion opens out an altogether new field of inquiry
respecting the origin of the disease, and it demands active and
thoughtful consideration in subsequent outbreaks. Dr. H. Day, of
Stafford, has endeavoured, by experiments on the lower animals, to
obtain some light on the subject. He fed three rabbits with unsound
grain (wheat, oats, ergot of rye, and mouldy bread) with this result:
In all the animals a spasmodic affection was produced, and in two
inflammatory changes in the right eye, proceeding in one case to

* Social Science Review, May 1865, p. 403.
ulceration of the cornea, and evacuation of the contents of the globe. One of the rabbits died on the eighth day, the other two were killed on the twelfth day, and in all more or less congestion of the membranes of the spinal cord was found on dissection.*

The sum of our knowledge of the etiology of epidemic cerebrospinal meningitis is this; that the clue to its explanation has not been discovered.

**NATURE.—1. Is the disease malarious, as suggested by some writers?**
The outbreaks in which the disease has occurred in malarious districts, or in which the malady has shown an intermittent character, are too few in number to admit of much, if any, doubt resting upon the answer. There is no sufficient ground for believing that the malady is of malarious origin. The numerous examples of prevalence of the disease in localities free from malaria set the question aside definitely. Even when intermissions or remissions have been observed in the progress of the malady, it must not be hastily assumed that they are consequent upon malarious poisoning. Hirsch has shown that certain cases of epidemic cerebro-spinal meningitis, distinguished by intermissions and remissions, which came under his own observation, took place in the course of an outbreak in a district free from malaria. Further, he states that this outbreak prevailed at a season (winter) and in a state of climate (intense cold) which notoriously exclude the prevalence of malarious diseases, even where endemic; that the period of life (1—5 years) least liable to malarious disease furnished the largest contingent of victims, while the classes most advanced in life, and who are most liable, escaped the epidemic in a remarkable degree. Finally, the infallible test of malarious disease, quinine, by its inutility in cases of the epidemic which assumed an intermittent or remittent character, showed the non-malarious nature of the affection.†

2. **Is epidemic cerebro-spinal meningitis a form of, or allied to, typhus?**
Epidemic cerebro-spinal meningitis differs from typhus in the aspect of the patient, rhythmical progress, range and course of temperature, form of cerebral affection, character of eruption, sequelae, rate of mortality, anatomical lesions, and manner of dissemination. Differing in all essential particulars, doubt can only arise when the two diseases prevail together. Under such circumstances, cases of the fulminant and purpuric forms of the one malady may be difficult to discriminate from the graver and more rapidly fatal forms of the other. Doubt also may arise when in the course of the former disease typhous or typhoid symptoms occur. But such a doubt applies equally to the discrimination of the disease from measles and typhoid fever, as from typhus. 3. **Is epidemic cerebro-spinal meningitis a true or a pseudoepidemic disease?** Is this disease a true epidemic disease in the sense of its being due to a specific, febrile poison (to which class of diseases

* Clinical Histories and Comments, pp. 18—23.
the term epidemic is now well-nigh alone restricted? Or is it a pseudo-epidemic malady, as being an exaggerated and more prevalent form, from certain climatic conditions, of an idiopathic inflammatory affection of the brain and spinal cord? No absolute distinction can be drawn between sporadic cerebro-spinal meningitis and the epidemic malady of the same name. But there are certain broad and well-defined differences. The conjoined inflammatory affection of the covering membranes of the brain and spinal cord, which is the rule in epidemic cerebro-spinal meningitis, is a rare exception in sporadic inflammation of the envelopes of the central nervous centres. Again, the indications of blood-change which are so common in the epidemic disease are never, or only in most exceptional cases, witnessed in the sporadic disease. It has been suggested that the blood-change and herpetic and purpuric eruptions may be of nervous origin, and consequent upon the profound alteration in the nervous system. It has been suggested, also, that the purpuric eruption of epidemic cerebro-spinal meningitis may be one of several signs of a general tendency to purpura in disease, and merely an incidental phenomenon of the epidemic malady. Thus, in Dublin (1866–67), purpura had been observed in rheumatic fever,* and there was an outbreak of purpura among swine,† contemporaneously with the epidemic. The first suggestion touches a very curious question, which as yet does not admit of solution. But it is worthy of remark that the form of eruption which of all others is peculiar to epidemic cerebro-spinal meningitis is the herpetic,—a form which, in some of its manifestations at least, as in herpes labialis, shingles, has singular neurotic relations. Mr. Jonathan Hutchinson has propounded the riddle, Is herpes zoster an exanthem or neurosis?‡ This is certain, that it is a symptom which has some definite connexion with lesion of nerve trunks, if not nerve centres. The facts upon which the second suggestion is based are of interest, but they form too narrow a basis for conclusions. It is noteworthy that rare cases of cerebro-spinal meningitis are observed in the intervals of epidemic prevalence of the disease, even in this country (H. Day; Wilks§). These cases are of much, although as yet undeterminate interest, in reference to the etiology of the disease.

4. Is epidemic cerebro-spinal meningitis a disease, sui generis? The association of symptoms shows that it is an independent malady; the aptitude to blood-changes in the course of the disease, judged by analogy with like changes which occur in acute specific diseases, suggests the inference that it also is dependent upon a specific poison, from whatever source derived. This is the deduction which appears to have the highest degree of probability in the present state of our knowledge.

An inter-current question arises here: is the fulminant form of epidemic cerebro-spinal meningitis really a variety of the disease, or

† Dr. Mapother, The Lancet, July 13, 1867, p. 39.
‡ London Hosp. Repr. vol. iii. p. 70.
§ The Lancet, April 15, 1865, p. 388.
a different malady altogether? Dr. R. D. Lyons maintains that in
the recent prevalence of the epidemic in Dublin, two independent
diseases existed. The one characterised by its collapse, profuse pur-
puric eruption, great rapidity of course, mortality, and absence of
anatomical lesion in the nervous centres after death, he designates
febris nigra; the other was the disease commonly known as cerebro-
spinal meningitis. But it is to be remarked that the two varieties of
disease have never been observed except in the same epidemic; that
they pass by insensible grades the one into the other; that the most
highly developed symptoms of the so-called febris nigra sometimes
occur together with the most marked symptoms of cerebro-spinal
meningitis; and that it is more consistent with experience to consider
the two series of symptoms as indications of one and the same
malady, rather than two maladies going forward at the same time in
the same patient. A second inter-current question is, whether the
purpuric form of the disease be of scurvy origin? The question
amounts to little more than a suggestion. There are no facts
which support an affirmative answer; for, apart from other well-
known signs, purpuric spots are not indications of a scurvy
taint.

Treatment.—Prophylactic.—Ignorance of the true etiology of the
disease limits our preventive efforts to general sanitary measures,
applicable to all epidemic diseases, for the purification of houses and
localities. Mr. J. Simon, recording the conditions under which the
disease has prevailed, writes:—"I am strongly of opinion that the best
sanitary precaution which in the present state of knowledge can be
taken against the disease, must consist in care for the ventilation of
dwellings." He adds, however, "that in some cases, according to local
reports, the distribution of an epidemic has very decidedly not been
governed by conditions of overcrowding and ill-ventilation." Dr. B. W.
Richardson's suggestion as to the cause of the disease should lead to the
careful microscopic examination of all bread-stuffs and farin-
naceous preparations in use among families and communities where
the disease breaks out, and the disuse of such as may be of doubtful
character.

Curative.—The treatment of epidemic cerebro-spinal meningitis is
as unsatisfactory as that of cholera. The evidence of the course of the
disease having been beneficially affected in any outbreak by the
administration of medicine is very doubtful. The too common rapid
progress of the malady to death, as in cholera, and the nature of the
lesions determining death, necessarily set at nought efforts to control
it; medicine not being guilty either of inaptitude or inactivity. The
control of this disease, as of cholera or typhus, is a question of
preventive rather than curative treatment, and must depend upon
the discovery and limitation of its cause. In the earlier outbreaks,
epidemic cerebro-spinal meningitis was treated, as an acute inflamma-
tory affection, by bleeding and purgatives, with the general result
that the fatality of the malady was probably invariably augmented. During the recent outbreak in Philadelphia, it was found that, in the more asthenic cases, cupping the nape of the neck was "of essential service in mitigating, and generally, indeed, in wholly removing the neuralgic pains which form so prominent and so severe a symptom in many cases of the disease" (Stillé). When the state of the patient forbade the abstraction of blood, dry-cupping used in the same locality afforded signal relief, and rendered the effects of vesication more prompt and complete. This was the experience of one of the least fatal outbreaks recorded. The experience of the majority of epidemics has been against any blood-letting, local or general. The deduction to be derived as to depletion from the general state of the circulation and the results of practice entirely coincide. For, as a rule, the pulse from the very onset contra-indicates the withdrawal of blood; and, if in any case it should seem from the general symptoms that depletion might exercise some control over the central mischief, a thoughtful regard should be given to the future. The application of cold to the head and spine, either by means of ice or a freezing mixture, in Esmarch's india-rubber bags, is not open to the same objection as blood-letting, and has furnished by far the most satisfactory results of all direct treatment of the acute cerebro-spinal symptoms. In its use care should be taken not to prolong the application so as to depress or increase the depression already existing of the whole system. When the acute nervous symptoms are accompanied by marked prostration, it is advisable during the application of the ice to swathe the limbs in hot flannels, pack the legs and thighs with hot-water bottles, or bags filled with hot sand or salt, and cover the abdomen with thick layers of flannel or cotton-wool. From the very outset of the disease, care should be taken to economise the temperature of the body, and anticipate its fall; and in cases characterised by collapse, or much vital depression, the application of external heat in the manner just suggested is a cardinal point of treatment. Of medicaments directly addressed to the nervous symptoms, opium is the most valuable. It is especially indicated when there are much restlessness, acute delirium, sleeplessness, hyperesthesia, and painful spasm. Morphia is the best form of administration, and subcutaneous injection perhaps the best mode. The drug should be given in decided and frequently repeated doses, and carefully watched. Stillé says of its use during the recent outbreak in Philadelphia: "We were in the habit of giving one grain of opium every hour, in very severe, and every two hours in moderately severe cases, and in no instance was produced either narcotism, or even an approach to that condition. Under the influence of the medicine the pain and spasm subsided, the skin grew warmer, and the pulse fuller, and the entire condition of the patient more hopeful. It seemed probable, however, that the full benefit of the opium treatment could be received by those only who were subjected to it in the early stages of the attack. Direct experience is here in perfect accord with the expectation
which a knowledge of the pathological processes involved in the disease would naturally suggest.”

A Committee of the American Medical Association has reported favourably of the sulphate of quinia in large doses, given at the very beginning of the disease. In some instances the drug seemed to abort the attack. The committee speaks also of favourable results reported from the combined use of ergot and chloride of iron. Some American physicians have given ergot in combination with belladonna, and belladonna in combination with quinine, but with equivocal benefit. Mercurials have been freely used, particularly in the form of calomel, but their effect has been most questionable, except as purgatives. Their indiscriminate use is to be utterly condemned, and their use at all to be discountenanced. A host of other medicaments have been made use of, of which it is requisite to note only iodide of potassium, bromide of potassium, and arsenite of potash. The circumstances under which the two former drugs have been used, and are most likely to prove beneficial, will suggest themselves to the practitioner. It does not appear that any decided good has arisen from their administration. In protracted cases of convalescence the arsenite of potash may prove a valuable remedy.

Of the general treatment of the patient the hot bath (102°—106°) is, when practicable, the most important. This should be followed, as recommended by the Committee of the American Medical Association, by frictions with warm oil or turpentine. The regimen should be generous and nutritious from the beginning of the disease. In the acute stages soup of some kind or other, or milk, is needed; and as soon as appetite returns, solid viands of any digestible character must be given. In the graver cases when there is much restlessness and spasm or stupor, and food cannot be given by the mouth from the patient’s refusal or inability to swallow, an attempt should be made to administer it by the rectum: when there is much thirst, the patient’s fierce desire for drinks may be freely indulged. The state of the pulse is the principal guide to the use of stimulants. Their administration as a special remedy independently of the indications which generally govern their use has not been followed by good results; but they are called for when the condition of the pulse and the aspect of the patient show manifest flagging of vital power. The sequelæ of the disease must be treated on ordinary principles.

Too frequently the state of the patient as to delirium, spasm, and irritability of the stomach prevents all internal treatment whether by medicine or food, and limits the efforts of the physician to external measures, restricting even their application. To this unhappy combination of unfortunate and uncontrollable conditions may reasonably be attributed to some extent the inefficiency of treatment.

Local Paralysis.               Local Anaesthesia.
NEURITIS AND NEUROMA.

BY J. WARBURTON BEGBIE, M.D., F.R.C.P.E.

Morbid appearances, the results of inflammatory action, are occasionally met with in nerves. Such are the consequences usually of injury; the nerves have been divided by a sharp instrument; or, if independent of wounds, they are in all probability connected with rheumatism or gout. There seems no reason to doubt that inflammatory action may likewise extend to nerves from the contiguous tissues.

In its general characters Neuritis resembles the inflammation of fibrous tissue. The fibrous investing sheath of nerves, or neurilemma, is indeed its usual seat; the appearances of inflammatory action being for the most part limited to it, and only seen in the form of red softening of the nervous tissue itself when the inflammation has been of an intense description.

A doubt as to the spontaneous occurrence of Neuritis has been entertained and expressed by several authorities. Boerhaave, for example, writes: “Nemo forte unquam vidit inflammationem in nervo; hæc vero si contingat, in sola tunica vaginali hæret.” Others, again, with even greater inaccuracy, have maintained the frequent existence of Neuritis.† Pathologically the inflammation of nerves may be acute or chronic; and these two conditions are described by Rokitansky as follows: The marks of the former (acute) are,—(a) Injection and redness. The injection presents a linear arrangement, and the redness is partly caused by injection, and partly by small extravasations. (b) Looseness, succulence, and swelling of the nervous cord, due to infiltration of serum into the tissue of the neurilemma, and into the sheaths between the primitive nervous filaments. The nerve has lost its smooth, white, glistening appearance; its neurilemma is opaque, and has a rough and wrinkled look. (c) Exudation. This is generally a grayish or yellowish-red gelatinous product, which sooner or later becomes firm. It occupies the sheath and tissue of the neurilemma, and is likewise effused between the primitive filaments themselves. (d) The cellular tissue around the nervous cord always participates in these changes;

* De Morbis Nervorum.
† See on this point Animaladversiones de Neuritide. Praxeo Medico Universæ Præcepta, autore Josepho Frank; Partis secundæ volumen primum, Sectio secunda, p. 181; also Elements of General and Pathological Anatomy, by David Craigie, M.D., p. 379.
it becomes injected, reddened, and infiltrated with a serous or serofibrinous fluid. Not only the neighbouring cellular tissue, but the sheaths of the muscles, the fascia, the subcutaneous cellular tissue, and the general integuments, become involved.

Such a degree of inflammation as that now described may terminate in resolution, occurring quickly or slowly in different cases, or in induration of the nerve, and a permanent loss of its function in whole or in part. If the latter be the result, the nerve continues thickened, and more or less misshapen, forming a grayish cord, which is sometimes marked with black pigment and crossed by varicose vessels. The nerve filaments diminish in size and finally disappear, this result being in part due to the pressure to which they are exposed by the inflammatory product, and in part to their interrupted nutrition, for the vessels are obliterated by the inflammatory process. (e) In a more intense inflammation the primitive nervous filaments are destroyed. They are found in a state of red or grayish or yellowish-red softening, while the neurilemma is easily torn. (f) The fluid product of the inflammation may be purulent; and if so, the nerve appears highly discolored, and infiltrated with purulent fluid tinged with blood. The neurilemma is then much altered, and readily gives way, while the nerve is converted into a yellowish-red, brownish-red, or chocolate-coloured pulp. The cellular tissue surrounding the nerve becomes infiltrated with yellow fibrinous exudation, and abscesses are formed in its course. (g) Ulcerative destruction of the nerve is the next step. But if the progress of inflammation be stayed before that point is reached, granulations appear, which become progressively changed into cicatrix tissue, as is observed in the stump of a nerve after amputation.

Nerves, however, resist for a lengthened period the suppurrative and-sanious destruction which may be going on around them.

Chronic Inflammation is characterised by the varicose state of the vessels of the affected nerve, by products which become indurated, and gradually increase in quantity, and by a change of the nerve to a slate or lead-gray colour. Sometimes the products are not deposited uniformly throughout the nerve, and then nodular swellings are formed on it.* Romberg, when directing attention to the anatomical knowledge we possess of sciatica, speaks of Neuritis being found, but of its rare occurrence.† The same writer, however, refers to the possible production of Neuritis, by the sciatic plexus being dragged and irritated by the head of the child in a difficult labour. Valleix and Beau have described inflammation of nerves more systematically than other authors. [The latter has at considerable length, in his interesting memoir on the subject, directed attention to "Intercostal Neuritis."‡ Reference has been made to the occurrence of a rheumatic or gouty

† Lehrbuch der Nervenkrankheiten des Menschen. Neuralgie des Hufnerven.
Neuritis. Dr. G. B. Wood considers it to be highly probable that in a large proportion of cases rheumatism lies at the foundation of the disease. And Dr. Garrod, while admitting, according to the usually received notion, that the nervous affections occurring in connexion with gout are generally functional, believes them sometimes to be dependent on inflammatory action, which, he adds, appears, so far as can be ascertained, to have the character of true gouty inflammation.

The most characteristic symptom of Neuritis is pain, not limited to the precise seat of the inflammation, but felt in the course of the nerve, and sometimes to its minutest branches. Besides its severity, the pain in Neuritis possesses other distinctive features: it is darting, and tingling, and there often accompanies it a feeling of numbness. The pain has been further described as intermittent, but is more probably remittent, being, as long as the disease continues, never entirely absent. Tenderness over the affected nerve invariably exists. It is possible that in some forms of local palsy (see Local Paralysis from Nerve Disease) the loss of power, partial or complete, as well as the existence of various morbid sensations, of which formication is one, and perhaps the most common, is due to disorganization or other permanent change in the trunk of a nerve, resulting from inflammatory action.

It seems to be generally admitted that the nerve most liable to such change is the sciatic; but the various branches of the brachial plexus, and especially the ulnar nerves, likewise suffer; and so in all probability do at times the other nerves in both lower extremities and trunk.

That inflammation may also attack the nerves of special sense, as Dr. Wood has conjectured, seems not improbable, particularly the nerves of hearing and of sight. Most assuredly a true gouty inflammation, apparently commencing, in some cases, in the nerves themselves, not unfrequently either damages or entirely destroys one or other of the delicate organs connected with these most important functions.

In the treatment of Neuritis the probable alliance of the affection with some peculiar diathetic condition, the gouty or rheumatic, or possibly with the syphilitic cachexia, must not be lost sight of. Local abstraction of blood, and the application of emollient and anodyne poultices, rest, low diet, and the use of laxatives, are the chief remedies in cases of the acute Neuritis. When the disease is chronic, the use of blisters, issues, and even the cautery, have been recommended. Internally, besides opium or other narcotic for the relief of pain, it will be prudent to give a fair trial in both the acute and chronic Neuritis to quinine, and colchicum, the iodide and the bromide of potassium.

Neuroma (Tumour of Nerve).—Growth various sizes and natures occurring in the course of nerves had been described before the term Neuroma came to be applied to such. Dr. Robert Smith, in his valuable

* A Treatise on the Practice of Medicine, vol. ii. p. 843.
† The Nature and Treatment of Gout and Rheumatic Gout, p. 517.
and elaborate memoir, makes a brief reference to the early history of
the subject;* and so likewise does Mr. William Wood, in his important
papers entitled, “Observations on Painful Subcutaneous Tubercle,”
and “On Neuroma.”† The famous English surgeon, William Cheselden,
is specially mentioned, as having given the first accurate account of
the nervous tubercle, which has become familiar chiefly through the
writings of Mr. Wood. “Immediately under the skin, upon the shin
bone, I have twice seen little tumours, less than a pea, round and
exceeding hard, and so painful that both cases were judged to be
cancerous: they were cured by extirpating the tumour. But what was
more extraordinary was a tumour of this kind, under the skin of the
buttock, small as a pin’s head, yet so painful that the least touch was
insupportable, and the skin for half an inch round was emaciated:
this, too, I extirpated, with so much of the skin as was emaciated, and
some fat. The patient, who before the operation could not endure to
set his leg to the ground, nor turn in his bed without exquisite pain,
grew immediately easy, walked to his bed without any complaint, and
was soon cured.” The same writer describes and figures the cystic
neuroma. “A tumour formed in the centre of the cubital (ulnar)
nerve, a little above the bend of the arm; it was of the cystic kind,
but contained a transparent jelly; the filaments of the nerve were
divided and ran over its surface. This tumour occasioned a great
numbness in all the parts that nerve leads to, and excessive pain upon
the least touch or motion. This operation (for the removal of the
tumour) was done but a few weeks since; the pain is entirely ceased,
the numbness a little increased, and the limbs as yet not wasted.”‡

The term Neuroma, or rather Neuromes, was first employed by
de Neuromes à ces tumeurs mobiles, circonscrites et profondes, qui sont
produites par le gonflement accidentel d’un nerf, à l’extrémité duquel
la compression de la tumeur fait éprouver des crampes très-pénibles.”§

There have been various classifications of neuromatous tumours
attempted by pathologists, such as local and general—that is, as affecting
one nerve, or several nerves; and, again, those which are the direct
consequence of a morbid process, and those resulting from an original
vice of conformation. Dr. Smith rejecting these divisions has sug-
gested, as sufficient for practical purposes, that Neuromata should be
considered as of two kinds: 1st, of spontaneous origin, or Idiopathic;
2d, as the result of wounds or other injuries of the nerves, and
therefore Traumatic.

Before offering a brief description of these varieties, it may be well
to direct attention a little more fully to the painful subcutaneous tubercle,

which we have the authority of Dr. Hughes Bennett and other pathologists for stating "must be referred to this class of tumours,"* that is, neuromatous fibrous tumours.

"Although," remarks Dr. Smith, "pathologists have hitherto failed to discover anything like nervous structure in these tumours, I still incline to the opinion that they are connected with the minute filaments and ultimate ramifications of the nerves. Upon any other supposition it is, I conceive, impossible to offer a rational explanation to account for the dreadful severity of the sufferings which they induce." Mr. Paget, who has carefully examined the "painful subcutaneous tumours," describes them as being formed of "either fibro-cellular or fibrous tissue, in either a rudimentary or a perfect state." Alluding to a case described by the late Professor Miller, in his "Principles of Surgery," and by Professor Bennett, the same pathologist admits that their structure may sometimes be fibro-cartilaginous.†

Of this affection the first detailed account was given by the late Mr. William Wood of Edinburgh. After the publication of Mr. Wood's earlier papers,* cases were recorded by different observers, and in 1829 an instructive résumé of the whole subject was laid by him before the Medico-Chirurgical Society of Edinburgh, and appeared, as already mentioned, in its "Transactions."

This disease consists in the formation of a small lump or tubercle seated in the subcutaneous cellular tissue, immediately under the integuments, which retain their natural appearance. The tubercle is met with in different parts of the body; but most frequently in the extremities. It is extremely small, pisiform in shape, of firm consistence, and apparently quite circumscribed.

The characteristic feature of the disease is the occurrence of violent pain coming on paroxysmally. The paroxysms vary in duration from ten minutes to upwards of two hours, their frequency as well as intensity appearing to increase in precise relation to the length of time the disease has existed. Some patients enjoy intervals of relief from pain for days or even weeks, while others have repeated attacks in the course of a single day. The paroxysms of pain frequently occur when the patient has fallen asleep. They are also apt to be excited by various external causes, such as pressure and blows; while in rarer instances mental disquietude and atmospheric changes have been their only apparent occasion.

Females are more frequently the subjects of this disease than males. Wood, referring to thirty-five cases collected by him, mentions that twenty-eight were females, five males; and in the account of two the sex was not stated. Of thirteen cases quoted by Descot, ten occurred in females, and three in males. Romberg has met with three instances, all in females.

The situation of the tubercle in the thirty-five cases referred to by

* Clinical Lectures on the Principles and Practice of Medicine. 3d edit. p. 171.
† Lectures on Surgical Pathology, vol. ii. p. 123.
‡ The Edinburgh Medical and Surgical Journal, 1812. Two Articles, pp. 285 and 429.
NEURITIS AND NEUROMA.

Wood was as follows: in the lower extremities in twenty-two, in the upper extremities in eleven, in the chest in one, and in one in the scrotum. In only two of these cases was there more than one tubercle present.

This disease does not seem to be intimately connected with any particular period of life, as it has been noticed at all ages from thirteen to above seventy.

"It is a happy circumstance that this very painful affection is capable of being remedied by a very simple operation. The tubercle is easily removed by a single incision, and it is unnecessary to take away any portion of the integuments, or of the surrounding cellular tissue. No bad effect can follow the removal of the little body."—Wood.

Although this subcutaneous tubercle has been considered as a variety of Neuroma, it must be held in remembrance that, its distinct connexion with branches of nervous trunks never having been determined, this is more a matter of inference than of demonstration. Ollivier and Rayer together carefully dissected the tumour in a case to which reference is made in his latest paper by Wood, and the result is thus expressed: "Extérieurement il était enveloppé de tissu cellulaire, dans lequel nous ne pûmes distinguer aucun filet nerveux, même à l'aide d'une forte loupe."* Paget remarks that the general opinion is against the supposition of the intimate connexion of these painful tumours with nerves. "Dupuytren," he writes, "says that he dissected several of these tumours with minute care, and never saw the smallest nervous filament adhering to their surface. I have sought them with as little success with the microscope. Of course I may have overlooked nerve-fibres that really existed. It is very hard to prove a negative in such cases; and cases of genuine Neuroma, i.e. of a fibrous tumour within the sheath of a nerve, do sometimes occur, which exactly imitate the cases of painful subcutaneous tumour."

We have now to consider the first of the two forms of Neuroma, as distinguished by Smith, and now generally recognised,—namely, the Idiopathic Neuroma. Tumours of this nature are of an oval or oblong form, their long axis corresponding with the direction of the nerve to which they are attached. They vary considerably in size. One figured in his work by Smith is as small as a grain of wheat, while another is as large as a good-sized melon. Between these two extremes every variety of size occurs. There may be only one, or several may be found on the same nerve; occasionally they are found existing simultaneously upon all the spinal nerves. "In number," says Rokitansky, "they vary from one until they are almost countless." A remarkable general disease is thus constituted, of which three cases have been observed in the Vienna Hospital. Neuromata are comparatively rare in the ganglionic system. But

although occurring most frequently on the spinal nerves, neuroma is not limited to them; the cerebral nerves motor, as well as sensory, particularly those most closely resembling the nerves of the cord, present at times the same tumours.

In general, neuromata are solid throughout their entire structure, but in some instances are of cystic formation, as in the case recorded by Cheselden, and already referred to. These tumours are of slow growth, but continue to undergo a steady increase in size, although many years may elapse before they attain such dimensions as to prove a source of serious inconvenience. They are moveable in the transverse direction, but not in the course of the nerve upon which they are seated. There may be a difficulty in distinguishing tumours which are merely contiguous to nerves from the true Neuroma, having its origin within the neurilemma. Wood has specially alluded to this difficulty in diagnosis, and Smith has pointed out that the non-nervous tumours, unlike Neuromata, are generally moveable in all directions, and when drawn away from the nerve, cease to be painful on pressure.

Nerve tumours are described by Rokitansky as lying between the fasciculi of the nerves, and interwoven with their neurilemmatous sheath. Neuroma, the same pathologist observes, is never deposited in the centre of a nerve, but at its side, so that only a small part of its fasciculi is displaced; the displaced fasciculi are spread abroad and stretched over the tumour, while the greater mass of the nerve remains on the other side uninjured, and with its fibres in connexion with one another.

The solid neuromatous swellings are of a tough elastic consistence, of grayish or pale yellowish-red colour, and are invested with a distinct fibrous sheath. Dr. Hughes Bennett thus describes them:—

"On being minutely examined, they are found to consist of fibrous texture more or less dense, the filaments often arranged in wavy bundles running parallel to each other, but occasionally assuming a looped form, or intercrossing with each other. I have also found them to contain groups of cells. Not unfrequently they are fibro-cartilaginous; sometimes with the cells closely aggregated together, at others widely scattered. In some of the neuromatous swellings described by Dr. Smith I found the fibrous tissue to present wavy bundles, among which a few granule and cartilage cells were scattered and shrivelled, apparently from the action of spirit." *

Neuromata seldom contract adhesion to the investing integuments, unless they have been subjected to continued pressure. Smith has never known them to suppurate, or to be removed by absorption. Pain has been generally considered to be a characteristic feature of neuromatous swellings. In this respect, however, there is infinite variety. When a single Neuroma exists, there is almost invariably much suffering. The pain, moreover, occurs suddenly and paroxysmally, darting along the nerve with the violence and instantaneousness

* Loc. cit. p. 171.
of an electric shock. On the other hand, in those examples of Neuroma which are distinguished by the number of the tumours it is not uncommon to find these occasioning little or no inconvenience to the patient.

It is exceedingly difficult to determine with anything like exactness the real cause of the paroxysmal attacks and sudden aggravation of severe pain which occur in this as well as in many other forms of disease of the nervous system. Mental emotions and the ordinary atmospheric vicissitudes have been generally assigned as the occasion of these occurrences in Neuroma.

Paget has some very interesting observations on the cause of pain in Neuroma, as well as on the nearly entire absence of all suffering which has been noticed in some cases; and founding on the observations of Smith and others, including himself, this excellent writer is no doubt correct when he states "that we cannot assign the pain in these cases entirely to an altered mechanical condition of nerve-fibres in or near the tumour. We must admit, though it be a vague expression, that the pain is of the nature of that morbid state of nerve force which we call neuralgic. Of the exact nature of this neuralgic state, indeed, we know nothing; but of its existence as a morbid state of nerve-force, or nervous action, we are aware in many cases in which we can as yet trace no organic change, and in many more, in which the sensible organic change of the nerves is inadequate to the explanation of the pain felt through them." In short, Paget argues for the pain being functional, and not necessarily dependent at least on an organic disorder. If such pain is found to be influenced by the remedies chiefly available for the relief of ordinary neuralgia—quinine, iron, arsenic, belladonna, stramonium, the bromide of potassium—this suggestion will receive corroboration.

We now know that such Neuromata as are the seat of severe pain and of continual irritation may give rise to attacks of the so-called sympathetic epilepsy. Instances of this nature are to be found in the writings of several authors, and it is sufficient here to refer to the well-known views of Brown-Séquard respecting the exciting causes of the epileptic convulsion, and of many other nervous affections. *

In the idiopathic form of Neuroma the pain is generally limited to the parts below the tumour; and the sign of the true Neuroma, signalized by Aransoohn, has been accepted by others,—namely, that when the trunk of the nerve is compressed above the tumour the pain ceases, and then the Neuroma previously acutely sensitive can be touched without any uneasiness being caused. The remark already made as to the solid variety of Neuroma not being necessarily painful applies likewise to the fluid or cystic tumour.

Our knowledge of the determining causes of Neuroma cannot be said to have advanced since the period when the important treatise of

Dr. Smith first appeared, and we are still compelled to adopt his expression, "I feel it must be confessed that we know nothing with certainty regarding the causes of Neuroma."*

Neuromatous tumours have been frequently removed along with the corresponding portion of the nerve on which they were situated; and such operations, while entirely relieving the patients from suffering, have not been succeeded by any considerable loss of sensibility, or of the power of voluntary movement, in the parts supplied by even large nerves.

The sciatic nerve may be divided, as in a case of severe neuralgia of that nerve, by M. Malagodi, and a portion of it excised, without permanently destroying the functions of the limb.

The magnitude of the nervous trunk, which is the seat of the disease, will of course largely determine the period at which complete or partial restoration of the function in the limb is established. In some cases a few months, in others a year and upwards, have elapsed; but sooner or later, in all recorded instances, the banished sensibility and motor power have been regained.

The interference with the calorific function of the nervous system is strikingly exhibited in cases of operation for Neuroma. Mr. Adams and Dr. Smith have drawn attention to the diminution of temperature in the limb after the removal of the tumour, and with it a portion of nerve,—a diminution readily noticed both by patients and operator, and which has lasted for a lengthened period, even after the restoration of the other functions.

It may then be concluded that when idiopathic Neuroma is seated in the hand, fore-arm, or upper arm (the positions in which it has most commonly been found), the operation of removal may be safely practised. It is possible that a similar plan might be adopted in the case of Neuroma in the lower extremity; but it is on record that amputation of the limb has been had recourse to by Chelius, in a case of nervous tumour occupying the popliteal space and stretching to nearly the centre of the back of the thigh. This was an illustration; and there are others which teach a similar lesson, of the disease having been permitted to attain a very large size,—so large as to prevent any attempt being made for its simple removal.

**Traumatic Neuroma.**—Under this division are to be included tumours of nerves resulting from any form of mechanical injury, such as wounds, blows, pressure, or following amputation.

Traumatic Neuroma is almost invariably single. The tumour is the seat of intense pain, which, unlike the suffering in the idiopathic form of the disease, is not confined to the growth itself, or felt merely in the parts below it, but is frequently found extending along the nerve towards its origin. When Neuroma occurs as a consequence of a wound of nerve, it usually consists of a solid tumour, not invested by

* Loc. cit. p. 5.
neurilemma, and destitute of any distinct capsule.* It is most likely to form when the nervous cord has been cut, but not entirely divided; and cases of this nature are even more than ordinarily painful.

The following case is published by Mr. Wood in his "Memoir on Neuroma;" it occurred in the practice of Mr. Syme:

"James Muir, aged 43, 30th June, 1828.—On the inner side of the left knee, about a hand-breath above the joint, there is a narrow depressed cicatrix, two inches long. Between this cicatrix and the sartorius there is a small tumour, about the size of an almond, and of very firm consistence. When the limb is extended, this tumour can hardly be perceived, being then overlapped by the sartorius; but when the knee is bent, it can be felt very distinctly. It is most moveable in a lateral direction, but seems pretty firmly connected to the subjacent parts by condensed cellular substance.

"The patient states that the tumour is always painful when pressed, but is more so at one time than another. The pain is not confined to the part, but shoots all over the knee, and sometimes extends from the groin to the toes. He observes that the pain is more severe during cold and damp weather. It frequently, for days together, prevents him from walking, or even resting on the limb. His story is, that when a boy, about eleven years old, he strained his knee by jumping into a saw-pit, which led to the formation of a large abscess that opened on both sides of the knee, namely, at the part where the cicatrix above mentioned still remains, and exactly opposite, where also there is a similar cicatrix. Several small bits of bone were discharged, and at the end of two years he got quite well. For the following twenty-seven years he led an active life; ten of them were spent in a militia regiment. About eight years ago he strained his knee while walking in his garden, and thereafter became subject to flying pains about the joints. These pains induced him to rub the knee frequently; and in doing so, about two years ago, he noticed the tumour. It was then the size of a pea, and has gradually enlarged. The disagreeable symptoms also have become greatly aggravated; and, as he refers them all to the tumour, he is desirous of having it removed.

"12th July.—Mr. Wood (continues Mr. Syme), who was kind enough to examine the patient, having agreed with me that the tumour was seated on or in the nervus saphenus, and that it ought to be removed, I performed the operation, with his assistance, on the 1st of July.

"The tumour being divided showed a firm fibrous capsule, containing a soft brownish-white pulpy matter. The nerve was traced into the tumour, but not through it. The patient made a good recovery, and remains free from his complaint."†

The foregoing case illustrates the proper treatment of Traumatic Neuroma, which is to excise the tumour with the corresponding

* Smith, loc. cit. p. 20.
† Loc. cit. p. 428.
portion of nerve, in every case when its situation will permit of this being done. *

The last form of Neuroma which requires any separate consideration is that succeeding to amputations. Smith remarks in regard to such, that "their existence is so constant that we may, perhaps, consider them as representing the normal condition of the ends of the nerves in stumps." Generally they cause no uneasiness whatever; but, on the other hand, they have occasionally been the occasion of severe neuralgia, occurring in paroxysms of great length.

The Neuroma of stumps varies in size, being in some instances not larger than a garden-pea, in others as large as a grape, or even plum. Such Neuromata are generally of an oval or oblong form, of grayish-white colour, and of a firm dense texture.

The situation of the Neuroma in the stump is not always the same; it may be several inches above the surface of the latter, and be connected with the cicatrix by means only of a fibrous cord, itself destitute of any nervous structure.

It is the opinion of some pathologists, that the Neuromata succeeding amputation are produced by the pressure which is exerted upon the surface of the stump. An objection fatal to this explanation, however, has been advanced,—namely, that in many stumps which have never been subjected to pressure these little tumours are found.

Dr. Smith believes their formation to be for the protection of the extremity of the nerve.

* Smith, p. 22.
NEURALGIA.

BY FRANCIS EDMUND ANSTIE, M.D., F.R.C.P.

DEFINITION.—A disease of the nervous system manifesting itself by pains, nearly always unilateral, which appear to follow the course of particular sensory nerves. The pains are usually sudden in their commencement, and of a darting, stabbing, boring, or burning character; they are at first unattended with any local change which can be recognised, or by any constitutional pyrexia. They are always markedly intermittent; sometimes regularly and sometimes irregularly so. The periods of intermission are distinguished by complete freedom from acute suffering, and in recent cases the patient appears quite well at these times. In old standing cases, however, persistent tenderness and other signs of local mischief are apt to be developed in the tissues which surround the distribution of the nerves which are the seat of the acute pains. Severe attacks of Neuralgia are usually complicated with secondary affections of other nerves which are intimately connected with that which is the original seat of pain; and in this way congestion of blood-vessels, hypersecretion, or arrested secretion from glands, inflammation and ulceration of tissues, &c., are sometimes brought about.

SYNONYMS.—The word Neuralgia has a generally recognised force, and there is no equivalent to it (except foreign variations in mere terminology) which represents the whole group of disorders to which it applies, though there are numerous phrases for particular forms of the disorder.

CLINICAL HISTORY AND SYMPTOMS.—These vary so greatly in different cases of Neuralgia that it will be necessary to discuss the greater part of this subject under the headings of the special varieties of the disease. There are certain features, however, which are observed in all true Neuralgias.

In the first place, it is universally the case that the existing condition of the patient at the time of the first onset of the disease is one of debility, either general or special. I make this statement with great confidence, notwithstanding the contrary assertion advanced by so high an authority as Valleix, whose able*

treatise really laid the foundation for all our accurate knowledge of the Neuralgias. In the first place, it is certainly the case that the larger half of the total number of patients coming under my care with various forms of Neuralgia are either decidedly anaemic or have recently undergone some exhausting illness or fatigue; and the reason why Valleix did not find so many cases of this type among his neuralgic patients appears certainly to be, that he limited the neuralgic class of diseases by an artificial definition, which we shall have to reject as untenable. On the other hand, although a considerable number of neuralgic patients are so far healthy in appearance, that they have a fairly ruddy complexion and a good amount of muscular strength, it is impossible to admit that these facts disprove the existence of debility, either structural or functional, in the nervous system, for the commonest experience teaches that such debility does frequently co-exist with a great robustness and development of the apparatus of vegetation and the lower forms of animal function. And it will invariably be found, on carefully examining these apparently robust neuralgic patients, that the nervous system has given warnings of its weakness: thus, the patient who, after an exhausting confinement, attended with great loss of blood, is attacked with obstinate clavus hystericus, will inform us that whenever in earlier life she had suffered from headache, the pain was always chiefly, if not altogether, confined to the nerves which are now the seat of decided Neuralgia. In a large number of cases I have also found that the attack of acute pain was immediately ushered in by a remarkably anaesthetic condition of the parts about to become painful; and a slighter degree of blunted sensation may often be observed in the intervals between the earlier attacks in cases of Neuralgia. In short, I have never seen a case of neuralgic pain in which there were not marked evidences of nervous debility, either local or general.

Another circumstance is common to all Neuralgias of superficial nerves; and as a large majority of neuralgic affections are superficial in situation, this is, for practical purposes, a general characteristic of the disease. I refer to the formation of tender spots at various points where the affected nerves pass from a deeper to a more superficial level, and particularly where they emerge from bony canals, or pierce fibrous fasciae. So general is this characteristic of inveterate cases, that Valleix founded his diagnosis of the genuine Neuralgias on the presence of these painful points, in which assumption I think there can be little doubt, that he committed an error.*

The third general characteristic of neuralgic affections is, that the pain is intermittent, or, at the least remittent, in every stage of the disease.

* Trouseau insists with much energy that a still more important "point douloureux" is constantly present in Neuralgia, viz. over the spinous processes of one or more vertebrae, corresponding to the origin of the painful nerve. It is true (as the Brothers Griffin had long before pointed out), that there is tenderness in this situation. But this "point apophysaire" is not always, nor frequently, the seat of spontaneous pain.
NEURALGIA.

The fourth general characteristic is, that fatigue and every other temporary depressing influence directly predisposes to an attack of acute pain, and aggravates it when already existent.

VARIETIES.—It is possible to classify the Neuralgias upon either of two systems: first (A), according to the constitutional condition of the patient; and, secondly (B), according to the situation of the affected nerves. It will be necessary to follow both these lines of classification, avoiding repetitions as much as possible.

(A) In considering the influence of constitutional states upon the typical development of Neuralgia, it will be convenient to commence with (I) the group of cases in which the general state of the organism exerts the least amount of effect. This is the case where the pain is the result of direct injury to a nerve-trunk, whether by external violence, by the mechanical pressure of a tumour, or by the involvement of a nerve in inflammatory or ulcerative processes, spreading to it from neighbouring tissues. As regards the development of symptoms, the important matters are, that the pain in these cases commences comparatively gradually, that the intermissions are usually much less complete, and that the pain is far less amenable to relief from remedies than in other varieties of Neuralgia. The little that can be said about the form which is dependent upon progressively increasing pressure, or involvement of a nerve in malignant ulcerations, cancers of bones, or teeth, &c., falls under the heads of Diagnosis or Treatment, and need not detain us here. The clinical history of Neuralgia from external violence, however, requires separate discussion.

1. Neuralgia from external violence may be produced by a shock (as of a fall, a railway collision, &c.), which gives a jar to the central nervous system, or by severe mental emotion, operating upon the same part of the organism. Under either of these circumstances the development of the affection seldom occurs at once, but ensues after a variable interval, during which the patient exhibits symptoms of general depression, with loss of appetite and strength. Sometimes vomiting, and even, in other instances actual paralysis of a partial and temporary kind occur. When once developed the neuralgic attacks are undistinguishable from those which occur from causes internal to the organism. The affection is usually very obstinate. In a large number of cases the nerve or nerves affected have previously shown signs of weakness, by a tendency to painful affection in depressed states of the organism. In the greater number of instances, as far as my experience goes, it is the fifth cranial nerve which becomes neuralgic from the effects of central shock. Illustrative cases will be given in the sections on local classification.

2. Neuralgia from direct violence to superficial nerves is produced either by cutting or, more rarely, by bruising wounds.

Cutting wounds may divide a nerve-trunk, (a) partially, or (b) completely.

(a) When a nerve-trunk is partially cut through, neuralgic pain
commonly occurs, if at all, immediately on the receipt of the injury. One such example only has come under my own care, but many others are recorded.* In this case the ulnar nerve was partly cut through with a tolerably sharp bread-knife, at a point not far above the wrist; partial anaesthesia of the little and ring fingers was induced but at the same time violent neuralgic pains in the little finger came on, in fits recurring several times daily, and lasting for about half a minute. Treatment was of little apparent effect in promoting cure, though opiates gave temporary relief, as did the local use of chloroform. The attacks recurred for more than a month, long after the original wound had healed soundly; and for a long time after this pressure on the cicatrix would reproduce the attacks. A slight amount of anaesthesia still remained when I last saw the patient, more than a year after the injury.

(2) Complete severance of a nerve-trunk is a sufficiently common accident, far more common than is the production of Neuralgia from such a cause; indeed so marked is this disproportion between the injury and the special result, that I have been led to the conclusion that a necessary factor in the chain of morbid events must be the existence of some antecedent peculiarity of organization in the central origin of the injured nerve. This opinion is rendered more probable by the fact that the consecutive Neuralgia is not unfrequently situated not in the injured nerve itself, but in some other nerve with which it has intimate central connexions. Two such examples are recorded in my Lettisomian Lectures,* in which the ulnar nerve, and one in which the cervico-occipital, respectively, were completely divided: in all three instances the Neuralgia was developed in the branches of the trigeminus. In all the cases which have come under my notice the Neuralgia, whether direct or reflex, set in at a particular period, viz. after complete cicatrization of the wound, and while the functions of the branches on the peripheral side were partly, but not completely, restored. The same obstinacy and rebelliousness to treatment was noticed as in other instances of Neuralgia from injury.

A few words must be given, before quitting the subject of Neuralgia from wounds of nerves, to the cases in which a foreign body lodges, with more or less laceration, in the substance of a nerve-trunk. I have never seen such a case; but many instances are recorded in which most violent and painful Neuralgia has been set up in this way. Not unfrequently the irritation produces no noticeable effect on the nerve actually pressed upon, but sets up Neuralgia in a nerve so distant that no connexion is suspected between the neuralgic pain and the original accident. The removal of a small piece of glass, or such other irritating body from the cicatrix of an old wound, has in several recorded instances put an end to neuralgic pains in quite another situation, for which all manner of remedies had long been tried. Sometimes the neuralgic pain has been accompanied by tissue degeneration of an alarming character, and these have likewise

* Vide Lancet, 1866.
Neuralgias which result from some local injuries of so peculiar a character as gun-shot wounds scarcely fall properly within the province of this article. The reader who desires to know all that can be said with regard to this particular class of affections is recommended to study the able and carefully compiled "Report" of Messrs. Mitchell, Morehouse, and Keen.*

The case of Neuralgia from injury, pressure, and local disease of nerves has been mentioned first, because this form of the disease is less influenced than others by general constitutional states. But it is an erroneous opinion, however common, that the general condition of the body is here without any influence on the development of the nerve-pain. It has been forcibly urged, by Dr. Brinton and Dr. Handfield Jones more especially, that a condition of general bodily vigour mitigates, and that constitutional debility decidedly aggravates, these forms of Neuralgia; and my own experience gives most practical proof of the justice of this argument.

(II.) Neuralgias of intra-nervous origin. As regards the constitutional conditions with which the several varieties of Neuralgia that arise independently of external violence, or disease of extra-nervous tissues, are respectively allied, the following preliminary subdivision may be made:—

1. Neuralgia of malarious origin.
2. Neuralgias of the period of bodily development.
3. Neuralgias of the middle period of life.
4. Neuralgias of the period of bodily decay.
5. Neuralgias associated with anaemia and mal-nutrition.

1. Neuralgias of malarious origin were formerly far more prevalent than they are at present, within the sphere of the English practitioner of medicine; with the general decline of malarial fevers, consequent on improved drainage and cultivation of lands, they have become constantly more scarce. In former times, on the contrary, they were so common, that they forced themselves on the notice of every physician. The term "brow-ague," to this day applied by many medical men to every variety of supra-orbital Neuralgia, is a relic of the older experience on this point; as is also the very common mistake of expecting all neuralgic affections to present a distinctly rhythmic recurrence of symptoms.

My own experience of malarial Neuralgia has been very limited, and I may as well say all that I know of its symptoms at once. In fact, though the out-patient practice of the Chelsea Dispensary and Westminster Hospital has afforded me a considerable number of examples of ague in past years, I have only seen two undoubted and one doubtful case of malarial Neuralgia, in all of which the fifth nerve was affected.

* Report on Gun-shot Injuries to Nerves, observed in the late American War, Philadelphia, 1864.
The periodicity in one of the genuine cases was regular tertian; in the other regular quotidian. An algid condition always ushered in the attacks; but this was gradually exchanged, as the pain continued, for a condition in which the pulse was rapid, soft, and bounding, and the strength was further depressed. In both of these cases there were unilateral flushing of the face, and congestion of the conjunctiva, to a slight degree, during the attack of pain. The pain became duller and more diffused contemporaneously with the lowering of arterial pressure (as estimated by Marey's Sphygmograph); and after the disappearance of active pain, moderate tenderness over a considerable tract around the course of painful nerves remained for some time. But there was no distinct development of the painful points of Valleix (to be hereafter described), a circumstance which I attribute to the rapid cure of the complaint, in each instance, by quinine.

2. Neuralgias of the period of bodily development.—By the "period of bodily development" is here understood the whole time from birth up to the twenty-fifth year, or thereabouts. This is the period during which the organs of vegetative and of the lower animal life are consolidating. The central nervous system is more slow in reaching its fullest development, and the brain more especially is many years later in acquiring its maximum of organic consistency and functional power. That portion of the period of bodily development which is antecedent to puberty is but little obnoxious to neuralgic affections. From the moment when puberty arrives, however, all is changed. In the stir and tumult which pervades the organism, and especially in the enormous diversion of its nutritive and formative nisus to the evolution of the generative organs and the correlative sexual instincts, the delicate apparatus of the nervous system is apt to be overwhelmed, as well as left behind, in the race of development. Under these circumstances the tendency to neuralgic affections rapidly increases. It will, however, be seen later that there is a great preponderance of particular varieties of the disease among the cases occurring during this period.

3. Neuralgias of the middle period of life.—By this period is meant the time included between the twenty-fifth and about the fortieth or the forty-fifth year. It is the time of life during which the individual is subjected to the most serious pressure from external influences. The men, if poor, are engaged in the absorbing struggle for existence and for the maintenance of their families; or, if rich and idle, are immersed in dissipation, or haunted by the mental disgust which is generated by ennui. The women are going through the exhausting process of childbearing, and supporting the numerous cares of a poor household in some cases, or are devoured with anxiety for a certain position in fashionable society for themselves and their children, or again they are idle and heart-weary, or condemned to an unnatural celibacy. Very often they are both idle and anxious.

It must not be supposed that there is a sharp line of demarcation between this period and the last: nevertheless it will be seen, when we come to discuss the local varieties of Neuralgia, that there are certain
broad differences in the general tendencies of the two epochs. It must
be noted that particular Neuralgias, which are first manifested in the
development period, frequently recur, under special provocation, in
the period of middle life.

4. Neuralgias of declining bodily vigour.—The period here referred
to is that which commences with the first indications of distinct
physical decay, of which the earliest that we can recognise (in persons
who are not cut off by special diseases) is perhaps the tendency to
atheromatous change in the arteries. The earliest development of
this symptom varies very considerably in date; but whenever it
occurs it is a plain warning that a new set of vital conditions has
arisen; and especially notable is its connexion with the characters of
the neuralgic affections which take their rise after its commencement.
The period of declining life is pre-eminently the time for severe and
intractable Neuralgias. Very few patients indeed are ever permanently
cured, who are first attacked with Neuralgia after they have entered
upon what may be called the "degenerative" period of existence.

Perhaps a separate heading should be reserved for those Neuralgias
which are the heralds of locomotor ataxy. But they seem naturally
to fall under the present class, although the nervous degeneration
which produces them is chiefly in the direction of sclerosis. The
character of these pains is fully described in the article on Locomotor
Ataxy.

5. Neuralgias which are immediately excited by anaemia or mal-
nutrition. Of the neuralgic affections which can be ranked within
this group, the sole characteristic worthy of note here is the circum-
stances in which they arise. It would seem that conditions of anaemia
and mal-nutrition simply aggravate the tendencies of existing weak
portions of the nervous system to be affected with pain; just as
they notoriously do aggravate lurking tendencies to convulsion and
spasms.

(B.) We come now to the consideration of local varieties of Neuralgia.
The primary subdivision of these may be made as follows:—

(I) Superficial Neuralgias. (II) Visceral Neuralgias. The superficial
Neuralgias may be subdivided thus:

(a) Neuralgia of the fifth (trifacial or trigeminal).
(b) Cervico-occipital Neuralgia.
(c) Cervico-brachial Neuralgia.
(d) Intercostal Neuralgia.
(e) Lumbo-abdominal Neuralgia.
(f) Crural Neuralgia.
(g) Sciatic Neuralgia.

This classification is taken from Valleix, and appears to me sub-
stantially correct.

(a) The most important group of Neuralgias are those of the fifth
cranial nerve.

Neuralgia of the fifth nerve always exhibits itself with especial
violence in certain foci, which Valleix was the first to define with accuracy. These foci are always in points where the nerve becomes more superficial, either in turning out of a bony canal, or in penetrating fasciae. In the ophthalmic division of the nerve the following possible foci are noticeable: (1) the supra-orbital, at the notch of that name, or a little higher in the course of the frontal nerve; (2) the palpebral, in the upper eyelid; (3) the nasal, at the point of emergence of the long nasal branch, at the junction of the nasal bone with the cartilage; (4) the ocular, a somewhat indefinite focus within the globe of the eye; (5) the trochlear, at the inner angle of the orbit.

In the superior maxillary division the following foci may be found: (1) the infra-orbital, corresponding to the emergence of the nerve of that name from its bony canal; (2) the malar, on the most prominent portion of the malar bone; (3) a vague and indeterminate focus, somewhere on the line of the gums of the upper jaw; (4) the superior labial point, a vague and not often an important focus; (5) the palatine point, rarely observed, but in some recorded cases the seat of intolerable pain.

In the inferior maxillary division the foci are:—(1) the temporal, a point on the auriculo-temporal branch, a little in front of the ear; (2) the inferior dental point, opposite the emergence of the nerve of that name; (3) the lingual point (not a common one) on the side of the tongue; (6) an inferior labial point, only rarely met with.

Besides these foci in relation with distinct branches of the trigeminal there is one of especial frequency, which corresponds to the inosculations of various branches. This is the parietal point, situated a little above the parietal eminence. It is small in size, the point of the little finger would cover it. It is the commonest focus of all.

Neuralgia of the fifth may attack any one, or all three of the divisions; the latter event is comparatively rare.* The most common is the case of its limitation to the ophthalmic division, and incomparably the most frequent foci of the pain are the supra-orbital and parietal points.

The most common of all the varieties of trigeminal Neuralgia is Migraine, or sick-headache. This is an affection which is entirely independent of digestive disturbances, in its primary origin, though it may be aggravated by their occurrence. It almost always first attacks individuals at some time during the period of bodily development. Under the influences proper to this vital epoch, and often of a further debility induced by precocious straining of the mental powers, the patient begins to suffer headache after any unusual fatigue or excitement, sometimes without any distinct cause of this kind. The unilateral character of this pain is not always detected at first; but as the attacks increase in frequency and severity, it becomes obvious that

* It is with much diffidence that I make this statement, as it is opposed to the opinion of Valleix. But my own experience is very positive on the matter; and, besides, it appears to me that Valleix's definition of Neuralgia, which I cannot accept as sufficiently expansive, accounts for his views.
the pain is limited to the supra-orbital, and sometimes to the ocular branches of the ophthalmic division of the fifth nerve of one side. In very rare cases, however, as in all forms of Neuralgia, the nerves of both sides may be affected. If the pain lasts for any considerable time, nausea, and at length vomiting, are induced. This is followed at the moment by the increase of the severity of the pain; but from this point the violence of the affection begins to subside, and the patient usually falls asleep. The history of the attacks negatives the idea that the vomiting is ordinarily remedial. This symptom merely indicates the lowest point of nervous depression; but it may happen that a quantity of food which has been incautiously taken, lying as it does, undigested in the stomach, may of itself greatly aggravate the Neuralgia, by irritation transmitted to the medulla oblongata. In such a case vomiting may directly relieve the nerve-pain. When the patient awakes from sleep, the active pain is gone. But it is a common occurrence, indeed it always happens when the Neuralgia has lasted a certain length of time, that a tender condition of the superficial parts remains for some hours, perhaps for a day or two. This tenderness is usually somewhat diffused, and not limited with accuracy to the foci of greatest pain during the attacks.

Sick-headache is not uncommonly ushered in by sighing, yawning, and shuddering—symptoms which remind us of the prodromata of some graver neuroses, to which it is probably related by hereditary descent.

Another variety of trigeminal Neuralgia which infests the period of bodily development is that known as clavus hystericus; clavus from the fact that the pain is at once severe, and limited to one or two small definite points, as if a nail or nails had been driven into the skull. These points correspond either to the supra-orbital or the parietal, sometimes both these are the seat of the pain. But for the greater limitation of the painful area in clavus, that affection would scarcely differ from migraine, for the former is also accompanied, when the pain continues long enough, with nausea and vomiting. The adjective hystericus is an improper and inadequate definition of the circumstances under which clavus arises. The truth is that the subjects of it are usually females who are passing through the trying period of bodily development; but there is no evidence to show that uterine disorders give any special bias towards this complaint. Both migraine and clavus are often met with in persons who have long passed the period of bodily development. But their first attacks have nearly always occurred during that period of life.

The adult or middle period of life is not, according to my experience, fruitful in first attacks of trigeminal Neuralgia. But when the neuralgic tendency has once been set up, there are many circumstances of middle-adult life which tend to recall it. Over-exertion of the mind is one of the most frequent; more especially when this is accompanied by anxiety and worry; indeed the latter is a more powerful cause than the former. In women, the exhaustion of haemorrhage at partu-
rition, or of menorrhagia, and also the depression produced by over-
lactation, are frequent causes of the recurrence of a migraine or a
clavus to which they had been subject when young. The middle
period of life is also most obnoxious, on the whole, to severe mental
shocks, and also to severe bodily accident, of a kind to produce
damage to the central nervous system. Special mention ought to be
made in the case of women, of the disturbing influences of the great
series of changes which close the middle period of their life,—viz. the
involution of the sexual organs. This is doubtless a very frequent
cause of the resuscitation of a tendency to facial Neuralgia which had
lain dormant, perhaps, for many years.

It is, however, the final, or degenerative period of life which pro-
duces the most formidable varieties of facial Neuralgia. Neuralgias
of the fifth which have previously attacked an individual, may recur at
this time of life without any special character except a certain increase
of severity and obstinacy. But trigeminal Neuralgias which now
occur for the first time are usually intensely severe and utterly incur-
able. These cases correspond with the affection named by Trousseau,
"tic épileptiforme," and it is of them, doubtless, that Romberg is
speaking, when he says that the true Neuralgias of the fifth rarely occur
before the fortieth year of life. These affections are distinguished by the
intense severity of the pain, the lightning-like suddenness of its onset,
and the almost total impossibility of effecting more than the most
temporary improvement in the symptoms. But they are also distin-
guished by another circumstance which too often escapes attention;
namely, they are almost invariably connected with a family taint of
insanity, and very often with strong melancholy and suicidal tenden-
cies in the patient himself, which do not depend on, nor are commen-
surate in their development with, the intensity of the pain which he
suffers. They are further remarkable for the frequency with which
they are attended with two special complications—viz. muscular
spasms, and the formation of exquisitely tender points, the least pres-
sure on which is enough to cause the most violent agony. Often, a
mere breath of wind impinging on them will produce a like effect.
The history of these cases is most wretched: the unfortunate patient
may survive for years before he completely succumbs to exhaustion;
yet every hour of his life is a misery. The act of masticating
usually causes intolerable darts of agony, and nutrition is often obliged
to be kept up by liquids. If mere broth and slop diet be adhered to,
there is probably under-nutrition which aggravates the Neuralgia.
And if, as often happens, the patient flies to drink as a relief, that
again hastens the degeneration of the nervous centres, and renders the
case more hopeless of cure than ever.

(b) Cervico-occipital Neuralgia. As Valleix has remarked, there
are several nerves (in fact the posterior branches of all the first four
spinal pairs) which are more or less capable of being the seat of this
affection. But amongst them all there is none comparable to the great
occipital, which arises from the second spinal pair; for the frequency
and importance of its Neuralgic affections. This nerve sends branches to the whole occipital and the posterior parietal region. On the other hand, the second and third spinal nerves help to make up the superficial cervical branch of the cervical plexus, which is distributed to the triangle between the jaw, the median lines of the neck, and the edge of the sterno-mastoid, and those to the lower part of the cheek. Then there is the auricular branch, which starts from the same two pairs, and supplies the face, the parotid region, and the back of the external ear. Then, the small occipital, distributed to the ear and to the occiput. And finally there are the superficial descending branches of the plexus. These, altogether, are the nerves which, at various points, where they become more superficial, form the foci of cervico-occipital Neuralgia.

The most typical example of this form of Neuralgia which has fallen under my own notice, occurred (after exposure to cold wind) in a lady about sixty years of age, who had all her life been subject to Neuralgic headache, approaching the type of migraine, and who came of a family in which insanity, apoplexy, and other grave neuroses had been frequent. The pain centred very decidedly in a focus corresponding to the occipital triangle of the neck. It recurred at irregular intervals, and in very severe paroxysms, and was entirely unaffected by any remedies, till blistering was tried, when it yielded at once. About twelve months later this patient suffered a severe hemiplegic attack of paralysis.

The tendency, however, of cervico-occipital Neuralgias, is certainly to spread towards the lower portions of the face, as observed by Valleix; in this case they become, sometimes, undistinguishable from Neuralgias of the third branch of the fifth. In the early stages of the disease, if the physician had been lucky enough to witness them, the true place of origin of the malady would have been easily discernible; at a later date it requires great care, and a very strict interrogation of the patient, to discover the true history of the disease.

Experience is too limited, if I am to judge by my own and that of the standard authors, to allow us to say anything of the conditions, as to age and general nutrition of the organism which specially favour cervico-occipital Neuralgia. Apparently, however, there is good reason for thinking that the immediately exciting cause of it is most frequently external cold. And I am inclined to think also that it is seldom a primary Neuralgia, but occurs usually in subjects who have already experienced other forms.

(c) Cervico-brachial Neuralgia.—This class includes all the Neuralgias which occur in nerves originating from the brachial plexus, as from the posterior branches of the four lower cervical nerves. The most important characteristic of the Neuralgias of the upper extremity is the frequency, indeed almost constancy, with which they invade simultaneously or successively several of the nerves which are derived from the lower cervical pairs. The neuralgic affections of the small posterior branches (distributed to the skin of the lower and back part of the
neck) are comparatively of slight importance. But the "solidarité," which Valleix so well remarked, between the various branches of the brachial plexus, causes the Neuralgias of the shoulder, the arm, fore-arm, and hand to be extremely troublesome and severe, owing to the numerous foci of pain which usually exist. Perhaps Valleix's description of these foci is somewhat fanciful and over-minute; but the following among these which he mentions I have repeatedly identified: (1) an axillary point, corresponding to the brachial plexus itself; (2) a scapular point, corresponding to the inferior angle of the scapula. (It is difficult to identify the peccant nerve here: the one to which it apparently corresponds, and to which Valleix refers it, is the sub-scapular; but we are accustomed to think of this as a motor nerve). Still it is certain that pressure on a painful point existing here will often cause acute pain in the nerves of the arm and fore-arm. (3) a shoulder point, which corresponds to the emergence, through the deltoid muscle, of the superficial filets of the circumplex; (4) a median-cephalic point, at the bend of the elbow, where a branch of the musculo-cutaneous nerve lies immediately behind the median cephalic vein; (5) an external humeral point, about three inches above the elbow, on the outer side, corresponding to the emergence of the cutaneous branches which the musculo-spiral gives off as it leaves the groove in the humerus; (6) a superior ulnar point, corresponding to the course of the ulnar nerve, between the olecranon and the epistrochlea; (7) an inferior ulnar point, where the nerve passes in front of the annular ligament of the wrist; (8) a radial point, making the place where the radial nerve becomes superficial at the lower and external aspect of the fore-arm. Besides these foci, there are sometimes, but more rarely, painful points developed by the side of the lower cervical vertebrae, corresponding to the posterior branches of the lower cervical pairs.

The most common seat of brachial Neuralgia in my experience has been the ulnar nerve; the superior and inferior points above mentioned being the foci of greatest intensity; an axillary point has also been developed in one or two instances which I have seen. Rarely, however, does the Neuralgia remain limited to the ulnar nerve, in the majority of cases it soon spreads to other nerves which emanate from the plexus. A very common seat of Neuralgia is also the shoulder, the affected nerves being the cutaneous branches of the circumflex. I am inclined to think, also, that affections of the musculo-spiral and of the radial near the wrist are rather common, and have found them extremely obstinate and difficult to deal with. One case has recently been under my care in which the foci of greatest intensity of pain were an external humeral, and a radial point; but besides this there was an exquisitely painful scapular point. In another instance, the pain commenced in an external humeral and a radial focus; but subsequently the shoulder branches of the circumflex became involved. A most plentiful crop of herpes was an intercurrent phenomenon in this case.
Median cephalic Neuralgia is an affection which used to be comparatively common in the days when phlebotomy was in fashion, the nerve being occasionally wounded in the operation. I have only seen it in connexion with this cause; that is to say, as a well-marked affection. One such instance has been under my care. But a slight degree of it is not uncommon, as a secondary symptom in Neuralgia affecting other nerves. The traumatic form is excessively obstinate.

In the Neuralgias of the arm we begin to recognise the etiological characteristic which distinguishes most of the neuralgic affections of limbs, namely, the frequency with which they are aggravated, and especially with which they are kept up and revived, when apparently dying out, by muscular movements. In the case above referred to, of Neuralgia of the sub-Scapular, Musculo-spiral (cutaneous branches), and radial, the act of playing on the piano for half an hour immediately revived the pains in fullest force, when convalescence had apparently been almost established.

The liability of particular nerves in the upper extremity to Neuralgia, from external injuries, requires a few words. The nerve which is probably most exposed to this is the ulnar. Blows on what is vulgarly called the funny bone are not uncommon exciting causes of the affection in predisposed persons: and cutting wounds of the ulnar a little above the wrist are rather frequent causes. The deltoid branches of the circumflex, and the humeral cutaneous branches of the musculo-spiral, are much exposed to injury. The radial nerve near the wrist is very much exposed both to bruises and to cutting wounds. So far as I know it is only when a nerve-trunk of some size is injured that Neuralgia is a probable result. Wounds of the small nervous branches in the fingers, for instance, are very seldom followed by Neuralgia. I have no statistics to guide me as to the effect of long-continued irritation applied to one of those small peripheral branches; but it is probable that that might be more capable of inducing Neuralgia. As far as my own experience goes, however, it would appear that a more common result is convulsion of some kind, from reflex irritation of the cord.

(d) Dorso-Intercostal Neuralgia.—This form of Neuralgia has of late years assumed a position of much interest, in consequence, chiefly, of its rather frequent association with unilateral herpes, a circumstance which has considerably helped to elucidate the pathology of the latter disease.

This disease is surrounded with considerable diagnostic difficulties. Some of these will be discussed under the heading of Diagnosis in part; but a few words must be given to them here. The disorder with which it is especially liable to be confounded is that for which Dr. Inman invented the term Myalgia, and which is represented in different localities by the affections called in old-fashioned phrase pleuro-dynia, lumbago, and (more generally) by the very inaccurate term muscular rheumatism, (there being no respectable evidence whatever to connect it specially with the rheumatic diathesis). The principal feature by which dorso-intercostal Neuralgia can be separated
from myalgia is its history; viz. its non-dependence, or much less dependence, on excessive or long-continued local muscular action than the latter complaint exhibits. There is also a more marked intermit-
tence in the neuralgic affections. Finally, though this only applies to a limited number of cases, the intercurrence of herpes is a decided diagnostic of the neuralgic character of the disease.

Dorso-intercostal Neuralgia is an affection of certain of the dorsal nerves. These nerves divide immediately after their emergence from the intervertebral foramina into a posterior and an anterior branch. The former sends filaments which pierce the muscles, to be distributed to the skin of the back; the latter, forming the intercostal nerves, follow the intercostal spaces. Immediately after their commencement the intercostal nerves communicate with the corresponding ganglia of the sympathetic. Proceeding outwards they at first lie between the pleura and intercostal muscles; towards the angles of the ribs they pass between the two layers of intercostal muscles, and, after giving branches to the latter, give off their large superficial branch. In the case of the seventh, eighth, and ninth intercostal nerves, which are those chiefly liable to Neuralgia, the superficial branch is given off about midway between the spine and the sternum. The final point of division, at which superficial filets come off, in all the eight lower intercostal nerves, is nearer to the sternum, and is progressively nearer to the latter in each successive space downwards. There are thus, as Valleix observes, three points of division: 1. at the inter-vertebral foramen; 2. midway in the intercostal space; 3. near to the sternum. And there are three sets of superficial branches (reckoning the pos-
terior primary division) which make their way towards the surface near these points.

In one of its forms, intercostal Neuralgia is one of the commonest of all neuralgic affections. I refer to the pain beneath the left mamma, which women with neuralgic tendencies so often experience, chiefly in consequence of over-lactation, but also from exhaustion caused by menorrhagia, and especially from the concurrence of this cause with the preceding one. Some care must be taken to distinguish this from the mere myalgic pain, which is produced by over-working the pectoral muscles in proportion to the existing state of their nutrition, and also by the vague conditions grouped under the name "Hysteria." The latter sort of pain is more diffuse in extent, and less markedly inter-
mittent, than Neuralgia, and its history is different: and the effect of rest is far more marked in the former than in the latter.

It is only of recent years that the Neuralgia which had often been observed to attend herpes zoster has been even thought of as essentially connected with the latter disease. It is to M. Notta that some of the earliest observations leading to the latter view are to be attributed. But the matter was much more fully discussed by M. Barensprung, in a paper published in 1861.* This author

showed the absolute universality with which unilateral herpes, where-
ever developed, closely followed the distribution of some superficial sensory nerve, and gave reasons, which will be discussed hereafter, for supposing that the disease originates in the ganglia of the posterior roots, and that the irritation spread thence to the posterior roots in the cord, causing reflex Neuralgia. This theory will be discussed further. Meantime, it seems to be established, by multiplied re-
searches, that though unilateral herpes may, and often does, occur without Neuralgia, and neuralgia without herpes, the concurrence of the two is due to a mere extension of the original disease, which is a nervous one.

In young persons zoster is not often attended with severe Neuralgia, but a curious half-paralytic state of the skin, in which numbness is mixed with formication, or with a sensation as of boiling water under the skin, precedes the outbreak of the eruption by some hours, or even a day or two. Painless herpes is commonest in youth. From the age of puberty to the end of life the tendency of herpes to be complicated with Neuralgia becomes progressively stronger. The course of events is different in different cases, however. Usually, in adult and later life, the symptoms commence with a more or less violent attack of neuralgic pain, which is succeeded, and for the time usually (though not always) displaced, by the herpetic eruption. This latter runs its course, and after its disappearance the Neuralgia very commonly returns again. In old people the after-Neuralgia is often distressingly severe, and most rebellious to treatment. Six weeks or two months is quite a common period for it to last, and in some aged persons it has been known to fix itself permanently, and cease only with life. In elderly subjects a further complication sometimes occurs. The herpetic vesicles leave obstinate and most painful ulcers behind them, which refuse to heal, and worry the patient frightfully, the merest breath of air upon them sufficing to cause agonizing darts of neuralgic pain. I have known one patient distinctly killed by the exhausting agony thus caused.

The foci of pain in intercostal Neuralgia are always found in one or more of the points, already mentioned, at which sensory twigs become superficial. In long-standing cases acutely tender spots are developed; not unfrequently the most decided of these are where they are too seldom sought for, namely, opposite the emergence from the inter-vertebral foramen.

(e) Dorso-lumbar Neuralgia.—The records of this affection are as yet in a state of considerable confusion. What has been done with any precision towards clearing up the history of the disease, related chiefly to the neuralgic affections of the pelvic organs in women; and to the Neuralgia of the testis in men, which will be treated of in a different place.

The principal foci of dorso-lumbar Neuralgia, when this affects external parts, are as following:—(1) the vertebral points, correspond-
ing to the posterior branches of the respective nerves; (2) an iliac
point, about the middle of the crista ili ; (3) an abdominal point, in the hypogastric region; (4) an inguinal point, in the groin near the issue of the spermatic cord, from whence the pain radiates along the latter; (5) a serotal or labial point, situated in the scrotum, or in the labium majus.

Such is the description given by Valleix; and as I have seen but few examples of the external forms of dorso-lumbar Neuralgia I can only rely upon his observation. The few severe cases of this kind of Neuralgia, which I have observed, have been distinguished by foci in the vertebral region, and over the crista ili; in two of these there were also distinct foci in the spermatic cord and testicle. In one patient there was an apparent focus of pain higher up in the groin also; but this man is a confirmed hypochondria, and his morbid sensations are so shifting as to be very unreliable in their indications.

(f) The next group of Neuralgias which must be described is the crural. This, after all, includes very few independent cases. There are very few primary Neuralgias of the crural nerve; Valleix had only seen two in his very large experience, and I cannot say that I have seen any. Neuralgia of the crural nerve is almost always a secondary affection, arising in the course of Neuralgia, which primarily showed itself in the external pudic branch from theplexus.

(g) The last, and one of the most important and numerous groups of external Neuralgias are the femoro-popliteal, or Sciatic.

Sciatica is a disease from which youth is comparatively exempt. Valleix had collected 124 cases; and in not one was the patient below the age of seventeen; only 4 were below twenty. In the next decade there were 22; in the next 30; and the largest number of cases, 35, were between the ages of forty and fifty. This completely tallies with my own experience; and seems to favour the suspicion which I have formed, that the pressure exerted on the nerve in locomotion and in sitting is one principal cause of the great liability to Neuralgia which distinguishes the sciatic nerve; and this idea seems to be favoured by the further fact elicited by Valleix, that from thirty years onward the number of male is greatly higher than that of female sciatic patients.

There are three very distinct varieties of the disease, however, according to my experience. The first variety is obscure in its origin, but may be said, in general terms, to be connected with a strongly marked nervous temperament, which is indicated in the female by a tendency to hysteria, and in the male by an abnormal sensibility to nervous impressions. The subjects of this variety of sciatica are mostly below the age of forty, and have generally been liable to other forms of Neuralgia; the actual attack of sciatica is excited by some bodily fatigue or mental distress which, on other occasions, has produced sick-headache, or intercostal Neuralgia, &c. Very many of these patients are anemic. The greater number of them are females, and in many (whether as cause or effect) there is decided amenorrhoea, and sometimes chlorosis. In this variety the pain, though chiefly affecting the sciatic nerve and its branches, is apt secondarily to invade
some of the nerves which issue from the lumbar plexus. I cannot avoid the suspicion, though the proof is most difficult, that the affection not unfrequently depends on, or is much aggravated by, an excited condition of the sexual apparatus: certainly, I have observed it with marked frequency in women who remain single long after the marriageable age, and in the case of several male patients there has been either the certainty or a strong suspicion of venereal excess. The actual outbreak of pain is generally sudden, but in many instances there has been a tendency to numbness, or abnormal sensations, in the skin of the back part of the thigh, or in some part of the course of the branches of the nerve for some time previously. Like all forms of sciatica, this affection is usually obstinate, and requires assiduous and sometimes prolonged treatment for its removal; but it is incomparably more manageable than other varieties.

The second variety of sciatica occurs for the most part in middle-aged or old persons who have long been subject to excessive muscular exertion, or have been much exposed to cold, and especially damp cold, or who have been subjected to both of these kind evil influences. One must include also, I think, in this group, a certain number of patients whose age need not be so advanced, but who have been liable, along with depressing influences of a constitutional kind, to prolonged pressure on the nerve from the habitual maintenance of the sitting posture, in their business, for many hours together.

The patients who suffer from this second variety of sciatica are mostly, as already said, of middle age or more; but this statement must be understood to be made in the comparative sense which refers rather to the vital condition of the individual than to the mere lapse of years. Many of them have hair which is prematurely grey; and in some the existence of rigid arteries, together with arcus senilis, completes the picture of organic degeneration. In particular cases where depressing influences have been at work for a long time, or unusually active, these appearances rectify the impression we should otherwise receive from learning the nominal age of an individual; this is especially the case with persons who have for a long time drunk to excess. I am at a loss to know how Valleix and many others can have overlooked the frequent occurrence of this type of constitution among the most numerous group of sciatic patients—those between thirty and fifty years of age: unless, indeed, we suppose that many of their "robust" patients were so fresh in colour and possessed such good muscular strength as to lead the physician to ignore the far more significant vital indications which are given by the above-mentioned appearances.

A prominent feature in this variety of sciatica is its great obstinacy and intractability. Another equally marked is the development, around one or more foci of severest pain, of spots which are permanently and intensely tender, and the slightest pressure on which is sufficient to renew the agony of acute pain: this development of tender points is far less marked in the preceding form of the disease. The places which are specially apt to present this
phenomenon are as follows:—(1) A series or line of points, representing the cutaneous emergence of the posterior branches, which reaches from the lower end or the sacrum up to the crista ili. (2) A point opposite the emergence of the great and small sciatic nerves from the pelvis. (3) A point opposite the cutaneous emergence of the ascending branches from the small sciatic which run up towards the crista ili. (4) Several points at the posterior aspect of the thigh, corresponding with the cutaneous emergence of the filets of the crural branch. (5) A fibular point, at the head of the fibula, corresponding to the division of the external popliteal. (6) An external malleolar, behind the outer ankle. (7) An internal malleolar.

Another circumstance which distinguishes the form of sciatica which we are considering, is the degree in which (above all other forms of Neuralgia) it involves paralysis. By far the largest part of the whole motor-nervous supply for the limbs passes through the trunk of the great sciatic; it might therefore be naturally expected that a strong affection of the sensory portion of the nerve would, in a reflex manner, produce some powerful effect on the motor element. This effect is most frequently in the direction of paralysis. Complete palsy is rare, but in a large number of cases which have lasted some time there can be no doubt that there is a positive and very considerable loss of motor power, independently of any effect which may be produced by wasting of muscles. It is of course necessary to avoid the fallacy which might be produced by neglecting to observe whether movement was merely restricted in consequence of its painfulness.

Anaesthesia is also a common complication of sciatica, far commoner, as I venture to think, than it has been represented either by Valleix or Notta. It is necessary, however, to be explicit on this point. In the early stages both of this form of sciatica and of the milder varieties previously described, there is almost always partial numbness of the skin previous to the first outbreak of neuralgic pain, and during the intervals between the attacks. By degrees this is exchanged, in the milder form, for a generally diffused hyperæsthesia around the foci of neuralgic pain, while other portions of the limb may still remain anaesthetic. In the severer forms it sometimes happens that, besides an intense hyperæsthesia of the skin over the painful foci, there is diffused hyperæsthesia over a greater part or the whole of the surface of the limb. But it is important to remark that both in the anaesthetic and the hyperæsthetic conditions (so-called), the tactile sensibility is very much diminished. I have made a great many examinations of painful limbs in sciatica, and have never failed to find (with the compass points) that the power of distinctive perception was very decidedly lowered.

Convulsive movements of muscles are met with in a moderate proportion of the cases of severe sciatica of middle and advanced life, in which affection they are entirely involuntary. They differ from certain spasmodic movements not unfrequently observed in the
milder form (and especially in hysterical women), for these are more connected with defective volition, and are, in truth, not perfectly involuntary. In several cases of inveterate sciatica I have seen violent spasmodic flexures of the leg upon the thigh. Cramps of particular muscles are occasionally met with. I have seen the flexors of all the toes of the affected limb violently cramped; and in one case the patient was troubled with severe cramps of the gastrocnemius. It is chiefly at night, and especially when the patient is just falling asleep, that this kind of affection is apt to occur.

A third variety of sciatica is the rather uncommon one (so far as my experience goes) in which inflammation of the tissues around the nerve is the primary affection, and the Neuralgia is a mere secondary effect, from mechanical pressure on the nerve which, however, is, apparently, not itself inflamed. I believe that these cases are sometimes caused by syphilis, and sometimes by rheumatism. It need hardly be said that this affection is essentially different, and requires a different treatment from Neuralgias in which the disturbances originate in the nervous system.

(II) Visceral Neuralgias.—This most important class of diseases still remains very much unknown; but it is constantly assuming a greater consequence. The Neuralgias of viscera, of which anything can with confidence be said, are the following:—(1) Cardiac, (2) Hepatic, (3) Gastric, (4) Peri-uterine (including ovarian), (5) Testicular, (6) Renal.

It is, however, unnecessary to describe the clinical history of these disorders here, since they will be treated of under the headings of the morbid affections of the particular organs which they infest.

Complications.—This part of our subject is of the greatest interest, and the facts regarding it are, to a considerable extent, of recent discovery. If we turn to the excellent treatises of Valleix and Romberg, which appeared about a quarter of a century ago, we find a very inadequate importance assigned to the secondary affections which occur in Neuralgia. The convulsive movements of the facial muscles which occur in the severer forms of tic douloureux could not fail, of course, to attract attention even from the earlier times. Of the functions of special sense Valleix only mentioned hearing as liable to be affected. Injection of the conjunctiva he spoke of as if it were a rare phenomenon in trigeminal Neuralgia. He did not mention modifications of nutrition at all, except those of the hair; and of modifications of secretion he only enumerated lacrimation, mucous flux from the nostril, and salivation as occasional phenomena. Of disturbances of the stomach he took a more appreciative view; and he mentioned, as a remarkable fact, that he never knew facial neuralgia caused by gastric disturbance, but had frequently observed the latter affection to occur in the course of a neuralgic attack, and apparently as the consequence of it. He gives no pathological explanation of the connexion between them.
It is to M. Notta* that we owe the first scientific treatment of this subject of the complications of Neuralgia. The importance of these secondary affections is particularly brought out by this author in his remarks on trigeminal Neuralgia, of which he analyses 128 cases. As regards special senses, he states that the retina was completely, or almost completely, paralysed in ten cases, and in nine others vision was interfered with; partly, probably, from impaired function of the retina, but partly, also, from dilatation of the pupil, or other functional derangement independent of the optic nerve. The sense of hearing was impaired in four cases. The sense of taste was perverted in one case, and abolished in another. As regards secretion:—Lachrymation was observed in sixty-one cases, or nearly half the total number. Nasal secretion was repressed in one case; in ten others it was increased on the affected side. Unilateral sweating is spoken of more doubtfully, but is said to be probably present in a considerable number of cases. In eight instances there was decided unilateral redness of the face, and five times this was attended with noticeable tumefaction. In one case the unilateral redness and tumefaction persisted, and were, in fact, accompanied by a general hypertrophy of the tissues. Dilatation of the conjunctival vessels was observed in thirty-four cases. Nutrition was affected as follows:—In four cases there was unilateral hypertrophy of the tissues; in two, the hair was hypertrophied at the ends, and in several other cases it was observed to fall off or to turn grey. The tongue was greatly tumefied in one case. Muscular contractions, on the affected side, were noted in fifty-two cases; of these, in thirteen, the contractions were in the muscles of the lip and nostril; in ten, there was tremor of the eyelid; in a great number many muscles were simultaneously affected. Permanent tonic spasm (not due to photophobia) was observed in the eyelid in four cases; in the muscles of mastication, four times; in the muscles of the external ear, once. Paralysis affected the motor oculi, causing prolapse of the upper eyelid, in six cases; in half of these, there was also outward squint. In two instances, the facial muscles were paralysed in a purely reflex manner. The pupil was dilated in three cases, and contracted in two others, without any impairment of light; in three others it was dilated, with considerable diminution of visual power. Finally, with regard to common sensibility.—M. Notta reports three cases in which anæsthesia was observed. Hyperæsthesia of the surface only occurred in the later stages of the disease.

Various other observers have added to this list of the secondary affections which may occur in facial Neuralgia the following:—Iritis, glaucoma, corneal clouding, and even ulceration; periositis, unilateral furring of the tongue, herpes unilateralis, &c.

All the above complications of facial Neuralgia, excepting glaucoma, have been under my own observation, and most of them I have seen in a great many cases. Moreover, my own attention had been called independently to the subject by my own unlucky personal expe-

* Archives Générales de Médecine, 1854.
I began, at the age of about fourteen, to suffer from attacks of unilateral facial Neuralgia in the right side (chiefly supra-orbital), which very soon assumed the type of severe migraine, such as it has already been described. A year or two later, the pains being at this time severe and frequent, there occurred a painful thickening and tunefaction of the periosteum round the brow, and also the formation of one or two dense white patches on the cornea, in the centre of which small phlyctenular ulcers appeared. About the same time, probably, there occurred a great thickening of the fibrous tissue, surrounding the upper end of the nasal duct, which caused a dense stricture of that canal. Some years later, when the attacks had become much less frequent, they recurred with great severity during the prostration brought on by choleraic diarrhoea. I then first noticed that the hair of the eyebrow was whitened opposite the supra-orbital notch, and that grey hairs were thickly strewn over the right side of the head for some time after the attack; and this phenomenon has occurred after every severe attack since that time. It only lasts in intensity for a few days, and the colour soon becomes partially restored to its original tint, but without any falling off of the hair. The latter fact seems at first difficult of belief; but I have most closely observed the phenomenon, and have since witnessed the same thing in several patients, both of my own and other practitioners. Another nutritive modification which I have seen in my own case is the formation of a dense epithelial fur on one half of the tongue.

There is another complication which, so far as I am aware, was first identified by myself as having a definite relation to facial Neuralgia: viz. erysipelatoid inflammation of the tissues to which the painful nerve is distributed. Some years ago I was much surprised at observing, in a woman aged thirty-two, a patient of the Chelsea Dispensary, a most acute attack of unilateral erysipelas of the face and head, supervening on some severe and frequently recurring attacks of Neuralgia, which affected all three divisions of the trigeminus, but was most violent in the branches of the ophthalmic division. On the occurrence of the erysipelas, the acute pain subsided, but the most intense tenderness remained for some days, and pressure anywhere in the track of the nerves would re-excite a momentary spasm of pain. Since that time I have been constantly on the look-out for similar cases, and have observed a good many either in my own practice or that of others. In several instances I have seen Neuralgia of the fifth actually terminate in an affection undistinguishable from ordinary erysipelas, limited to the painful parts: in four of these cases it was limited to the side of the nose, the infra-orbital and frontal regions. But the facts bearing on a connexion between facial neuralgia and erysipelas, are by no means limited to this. In twenty-two cases which have come under my care, of patients suffering either from typical facial tic, from migraine, or from clavus hystericus, I have discovered, by inquiry, the existence of a strong tendency to erysipelatoid inflammation of the
parts then affected with Neuralgia. An attack of erysipelas would be brought about, in these patients, by the most trivial causes, by a slight exposure to cold winds, or, on the other hand, by unusually depressing fatigue, or emotion. The majority of these patients gave me a family history which showed a marked inherited disposition to neurotic affections, a circumstance which, as we shall hereafter see, is of importance.

Perhaps the most striking of all the cases which have come under my notice is one which was obligingly sent to me by Mr. Ernest Hart, and which I have already published* in detail. The exciting cause of the whole train of phenomena was apparently fright, from an accident which there was no reason to suppose inflicted any direct physical injury. The sequence of events was: (1) abrupt cessation of menses, with hysterical depression; (2) severe neuralgia of the first and second divisions of the fifth, quickly producing iritis, with effusion of lymph; (3) erysipelas, exactly limited to the skin of the painful parts, and as it were supplanting the Neuralgia.

The concurrence of iritis with the erysipelas, in this case, is a most interesting fact, as showing a general tendency to paralysis of the vessels in the affected district, which will be much dwelt on in the section on pathology. The connexion of iritis with Neuralgia is a subject which, although only quite recently mooted, already assumes an extraordinary magnitude, and may yet lead to pathological and therapeutic discoveries of first-rate importance. For my own part I do not hesitate to express the belief that the very vague and ill-defined disease known, in common phrase, as "Rheumatic iritis," is destined to be almost, if not quite, banished to limbo; for that careful observation will prove the cases so denominated to be nearly all capable of classification as "Neuralgic iritis."

The symptoms which characterise this malady are as follows. The patient first of all complains (usually after exposure to cold wind, or damp, or both) of pain round the orbit, which gradually increases to a pitch of great severity, but which exhibits marked intermissions or at least remissions. The vessels of the conjunctiva, but more particularly of the sclerotic, then become injected. Last of all the iris itself becomes cloudy, and, in severe cases, actual deposits of lymph take place. I cannot hesitate to say, from careful inquiries into the past history of such patients, that this kind of affection occurs quite as frequently in persons who have never shown any distinctive rheumatic tendencies as in those who have. On the other hand there is nearly always a recognisable history of tendencies towards neuralgic affections of one sort or another. And indeed, with regard to the whole series of so-called chronic rheumatic affections of fibrous membranes, it must be remembered that there is reason to doubt whether, on careful analysis, their local symptoms can be grouped into any intelligible unity. It seems far more likely that, as the consequences of spinal irritation become more perfectly known, the whole group of such

NEURALGIA.

affections will be resolved into particular cases of centric nervous irritation.

And finally, it may be noted that this variety of iritis is greatly more amenable to the influence of quinine than to that of any other remedy; in fact, beyond the use of belladonna to prevent pupillary adhesion, no other treatment is required.

Herpes, as a complication of dorso-intercostal Neuralgia, has been already referred to. Although not so commonly, it may probably attend Neuralgia of any superficial nerve. For instance, the occurrence of a regular facial herpes zoster has been considered by many authors not so much a rarity as an impossibility. But various single cases have been recorded by individual observers of late years, and in a very valuable paper on unilateral herpes in the London Hospital Reports for 1866, Mr. Jonathan Hutchinson reckons up fourteen cases, including several which came under his own observation: some of them are mentioned to have been accompanied by Neuralgia of the fifth. In one of these cases, in which the Neuralgia was particularly severe, the herpetic vesicles were followed by ulcers, which left considerable scars on the forehead. I have myself seen herpes the attendant of two cases of cervico-brachial Neuralgia, in one of which the ulcerations following the vesicles were a cause of severe suffering; and in one instance of sciatica in my practice there occurred enormous vesicles, or rather bulla, on the back of the calf, which formed most troublesome and exquisitely painful ulcers. Baresprung* records a similar case, in which the irritation of the sciatic was secondary to psoas abscess.

The tendency of deeper tissues to be affected in an inflammatory manner as a consequence of Neuralgia, which is specially shown in the cases of neuralgic iritis, receives every-day illustration. In fact, the painful points so universally observed in severe or inveterate cases are probably produced by a sub-acute inflammation, first of the fibrous membranes (periosteum or fascia) in contact with the nerve at points where it comes out from a deeper to a more superficial position, and further (in some cases) to all the sub-cutaneous tissues for an inch or two round. In one of the cases of cervico-brachial Neuralgia already referred to, a bright red painful spot, as large as half-a-crown, appeared on the outer side of the arm; there was dense thickening of tissues in this situation, and the resemblance to an inflamed syphilitic node was remarkable. The neuralgic origin was, however, unmistakeable. Among the cases of facial herpes collected by Hutchinson, there are several in which serious, or even irremediable damage was inflicted on the eye by general inflammation of its tissues.

DIAGNOSIS.—The diagnosis of neuralgic affections from others which may involve pain is, on the whole, not difficult, if we are able to extract from the patient a full account of his history. The essential points for observation are:—1. The situation and direction of the

* Loc. cit.
pain, whether this is unilateral, whether it corresponds to the course of a recognisable nerve branch or branches. 2. Whether it is intermittent, or markedly remittent. The points of history which are most important are:—1. Whether the patient has suffered Neuralgia before, and if not, whether neuralgias, or neurotic diseases of any kind, have prevailed in his family. 2. Whether the attack was preceded by nervous depression, or was ushered in by distinct numbness or tingling. 3. Whether the immediate excitant appeared to be cold or damp, or both, or a severe nervous shock, or a direct physical injury. 4. (If the affection has lasted some time) whether there has occurred any development of secondary tender points in the situations where, as above described, they might be expected. 5. Whether the patient has suffered from secondary affections of glands (e.g. lachrymation, in the case of facial pain) during the attacks, or of temporary congestion of surfaces (e.g. of the conjunctiva) in the same case, or from alterations of epithelium or hair, or herpetic eruptions, or erysipelas-like inflammation of the skin corresponding to the distribution of the affected nerves.

The affirmative answer to any of these questions is, pro tanto, in favour of the genuinely neuralgic character of the disorder; and, indeed, the union of features 1 and 2, under the heading of "observation," with one, or still more with two or three, of the "historical" facts, would be pretty well decisive in this sense.

The main source of embarrassment, in difficult cases of diagnosis, is the impossibility which we sometimes encounter of getting a clear history. This is especially apt to occur when we are called to the patient not so much on account of the primary neuralgic affection as because of severe secondary consequences that happen to have arisen. For instance, in a case of severe Neuralgia of the fifth, attended with periosteal inflammation round the orbit, or with intense conjunctivitis, and, it may be, coma, or even iritis, the history related is likely enough to lack explicit details of the primary affection. It is necessary to inquire very strictly whether the pain, when it first occurred, was, or was not, accompanied by tenderness on pressure; and whether this simple pain markedly preceded the organic lesions.

Another serious difficulty arises, not unfrequently, in distinguishing between true Neuralgia, and that form of pain which is vaguely called hysteric; and also between the former, and Myalgia not associated with the hysteric diathesis. The great characteristic of true Neuralgia is the limitation of the pain to the course of recognisable branches of nerves, as opposed to the diffused character both of hysteric and neuralgic pains. A history of intense hysteric predisposition may help the diagnosis in some cases, and a history of overwork done by under-nourished muscles may clear it up in others. But hysterical persons may, and sometimes do, suffer from true Neuralgia. And again, it is very common for hysteric patients to develop tender points in certain situations (especially beneath the left mamma, in the epigastrium, and at various situations
along the vertebral fossae which lodge the great muscles of the back, which bear a superficial similarity to the tender points developed in long-standing Neuralgia. The more generalised hyperaesthesia of the skin which usually accompanies these symptoms, when they are due to hysteria, will seldom be observed, however, in true Neuralgia; and the remarkable affections of volition which mostly accompany the hysteric diathesis rarely occur in Neuralgia pure and simple. A means of diagnosis between hysteric hyperaesthesia and the true Neuralgia which I have found most useful is the use of Faradisation. It has a strikingly inactive effect in the former, but acts much more slowly, or not at all, in true Neuralgia.

It is almost impossible to lay down rules of diagnosis, in this place, between neuralgia pure and simple, and that which accidentally occurs from a nerve becoming squeezed, or otherwise damaged, in the progress of tumours or other organic diseases external to it. The reader must be referred to the diagnostic characters mentioned in the treatises on such diseases for the means of distinction.

The neuralgic pains which usher in locomotor ataxy, are highly peculiar, and their diagnosis from ordinary Neuralgia must be learned by studying the article on the former disease.

**Prognosis.**—The prognosis of Neuralgia is nearly always an uncertain matter. The simplest case is when a clearly malarial history can be made out, and when the blood infection has not lasted too long: here we may expect a speedy cure by appropriate treatment. The least complicated varieties of traumatic Neuralgia—those in which the irritation is only kept up by some mechanical irritation (e.g. a foreign body lodged, or a tight cicatrix making pressure)—of course offer a good chance of cure by surgical interference. Among the Neuralgias which are more purely of internal origin, those are chiefly to be regarded as benign which occur in young subjects; and next to youth in favourable influence on the prognosis comes the fact of otherwise unbroken health. Neuralgia becomes progressively less curable in each successive decade of life, and more especially after the commencement (at whatever nominal age) of the symptoms of organic degeneration. Very formidable, in all cases, is the fact that the patient’s family have been liable either to severe Neuralgias, or to other grave neuroses. And when a patient with such a family history is first attacked with a Neuralgia after he has already entered on the period of organic degeneration, his chances of complete recovery must be reckoned very small. Moreover, such a Neuralgia is not unfrequently the first warning of a degeneration of the centres, which will end with softening of the brain.

These are the fundamental points in prognosis. A less essential, but still important, class of momenta are the circumstances of the patient’s life; how far, for instance, he is likely to be exposed to the hostile influences of cold, damp, and privation, with the disorders which they tend to engender; and how far there may be
unavoidable exposure to the influences of mental distress, or of the weariness of an objectless life.

Pathology and Etiology.—These two subjects, in the case of Neuralgia, are inextricably mixed; nor is it possible to discuss the one without constant reference to the other. They are so mixed, firstly, because there is no sufficient basis of anatomical fact to support a "pathology," in the ordinary sense; and secondly, because, in addition to the philosophical difficulties which always beset the construction of an etiological system, there are, in the case of Neuralgia, special obstacles to the decision as to what is "cause" and what "effect," arising from the necessity of regarding a neuralgic person as a mere offshoot of a certain family beset with peculiar tendencies, rather than as an individual who forms his own physical destiny by the manner and circumstances of his life.

Of facts tending to elucidate the morbid anatomy of Neuralgia there are very few. This necessarily follows from the rarity with which neuralgic patients die under circumstances which lead to any careful examination of the nerves and nerve-centres. Among the very few recorded cases which show anything positive is the remarkable one related by Romberg.* The patient was a victim to the severest form of facial Neuralgia, "of the period of bodily degeneration" such as I have described it. The Gasserian ganglion of the painful nerve was almost destroyed by the pressure of an internal carotid aneurism, the trunk and posterior root of the nerve were completely degenerated, and the atrophic process had extended, in less degree, to the nerve of the opposite side.

This case, alone, of course proves nothing as to the general question of the pathology of Neuralgia. But it teaches a notable fact, that the extremity of pain can be suffered in a nerve in which sensation would soon have become extinct by dissolution of the connexion between centre and periphery. It is imaginable that a not less real, but less advanced and less coarsely obvious atrophic change may have been present in every case of Neuralgia, even where dissection has failed to reveal anything amiss. It must be remembered that the microscopic study of morbid changes in nerve tissues is even now only in its infancy. It would be vain to occupy a large space, in a practical treatise, with disquisitions on a subject at present so obscure as the pathology of Neuralgia; I shall therefore content myself with stating the hypothesis which appears most probable to me, and the mere outline of the reasons which incline me to adopt it.

I think it most probable that in all cases of Neuralgia there is either atrophy, or a tendency to it, in the posterior or sensory root of the painful nerve, or in the central grey matter with which it comes in closest connexion. The following are the heads of the argument:—

1. Neuralgia is eminently hereditary. It is constantly observed to prevail in particular families, breaking out in successive generations

and various individuals. But what is even more important to notice is the fact that these neuralgic families are almost invariably also distinguished by a tendency to the severer neuroses—insanity, cerebral softening, paralysis, epilepsy, hypochondriasis, or an uncontrollable tendency to alcoholic excess; and very often in the various members of the same family we may observe the alternation of all these affections, and of Neuralgia, in various members.

2. Such hereditary tendencies in a race seem strongly to suggest a tendency to imperfection in the congenital construction of the central nervous system; so that we may imagine that certain cells and fibres of this system are, in a large proportion of that race, built, as it were, only to live with perfect life for a short term. The weak spot may be in one place in this person, in another place in that.

3. Given such a weak spot, congenitally present, all hostile influences will tell more heavily on it than on the rest of the organs. The depressing influence of cold applied to the periphery, of a wound of the trunk or branches of a nerve, of a severe shock (mental or physical) to the nervous centres generally, or of continued alcoholic excesses, will suffice to throw the imperfectly constructed cells into a state of positive disease, which may end in decided atrophy. Even in the absence of any special external cause, the depressing influence on the nervous centres produced by the great crises of puberty, childbearing, the involution of the female organs at the grand climacteric, and still more the partial failure of nutrition which the arterial degeneration of advanced life would cause—any of these may suffice to start the local morbid process.

4. A very weighty argument in favour of the idea that central mischief is a factor in all cases of Neuralgia is the great frequency of complications, such as have been described, in which various nerve-fibres, quite distinct from those which are the seat of pain, and connected with these only through the centre, are secondarily affected.

5. Those cases in which a localised peripheral lesion is the immediate excitant also require for their explanation the assumption of a peculiarity in the individual, as one factor, and that the most important, in the production of the Neuralgia. For of hundreds of persons to whom exactly similar lesions happen every year, not more than two or three, perhaps, experience any Neuralgia; and these two or three will, I believe, be invariably found to belong to neurotic families.

6. The only cases to which the theory of congenital central imperfection appears neither applicable nor necessary are those in which a pressure, ulceration, or other lesion extending from neighbouring tissues towards the nerve, maintains a constant depressing centripetal influence which it is not difficult to suppose might impair the vitality of the posterior root, or of the central grey matter.

7. Certain influences, especially that of excessive drinking, which notoriously tend to produce degeneration of the nervous centres, are powerful predisposers to the production of Neuralgia of the inveterate
Moreover, the descendants of drunkards, among other evidences of an enfeebled nervous organization, are decidedly prone to Neuralgia. So frequently have I made the discovery that neuralgic patients have had drunken parents, that I cannot suppose the coincidence to be accidental.

**TREATMENT.**—The treatment of Neuralgia may be classified under three heads. The first division includes all remedial measures which are intended to improve the general nutrition, including that of the nervous system, or to remove any vicious condition of the blood which may impair nervous function. The second division includes the narcotic stimulant remedies. The third division comprises all the remedies which are destined to exert a direct influence upon the affected nerve.

1.) Constitutional treatment.

(*a*) Under the head of *nutritive* remedies for Neuralgia, by far the most important sub-class is the series of animal fats. There is a theoretical basis for the use of these substances which it is impossible to ignore, although I have no desire, in the present state of our knowledge, to insist too absolutely upon it. In some way or other, fat must undoubtedly be applied to the nutrition of the nervous system, if this is to be maintained in its organic integrity; since fat is one of the most important, if not the most important, of its organic ingredients. But if our theoretical ideas on this point be as yet deficient in the exactness which is to be desired, there can be no doubt, I think, that the practical lessons which they would teach are abundantly verified in experience. If we take, for instance, the class of Neuralgias which are most plainly and indubitably connected with impaired nutrition—those of advanced life, and particularly the inveterate forms of facial tic douloureux—there is the strongest ground, in the results of experience, for insisting upon the value of this class of remedies. To Dr. Radcliffe belongs the merit of having been chiefly instrumental in bringing forward this therapeutical fact in this country, and it is one which I have had repeated occasions to verify. It is a very singular circumstance, which also was first pointed out by Dr. Radcliffe, that neuralgic patients are, in the majority of instances, found to have cherished a dislike to fatty food of all kinds, and to have systematically neglected its use. I have also obtained strong evidence that this is the general rule, and the reverse a rare exception. And it has several times occurred to me to see patients entirely lose neuralgic pains, which had troubled them for a considerable time, after the adoption of a simple alteration in their diet, by which the proportion of fatty ingredients in it was considerably increased.

Cod-liver oil occupies the highest rank among fatty remedies; where it does not immediately disagree with the stomach, this oil is the best fat to employ. But in other cases butter, and especially cream, may be employed with great advantage; and in fact one of the most successful examples of the treatment of Neuralgia which
I record was treated solely by the administration of Devonshire cream in increasing, and finally in very large quantities. Even the vegetable olive oil, though far inferior to animal fats as a general rule, may occasionally be used with good effect. It is necessary in many cases to make a series of trials, before we arrive at the particular form of fatty food which is best suited to the particular patient.

(6) The various preparations of iron are of use, so far as I know, only in cases which are marked by the existence of actual anaemia. For patients who possess well globulated blood (as indicated not merely by the colour of the face, but by that of the mouth and tongue, especially by the freedom of the latter from teeth-markings, and by the absence of the drowsiness, muscae volitantes, &c., which indicate defective blood-nutrition of the brain) I do not believe that iron treatment has any value. The carbonate, in large doses, is the best form, when iron is needed at all.

(c) The employment of the so-called special nerve-tonics is of great use in some cases, of none at all in others. Quinine, arsenic, and zinc (in various preparations) are the only medicinal substances of this class which possess any solid claims to efficacy.

With regard to the efficacy of quinine there are the most conflicting opinions, except in one respect. No one doubts that in the Neuralgias which are of malarious origin this medicine, though not infallible, is extremely efficacious. It should be administered, in all cases which from their regular intermittence leave room for a suspicion that this may be their nature, in full doses (five to twenty grains) shortly before the time at which the attack of pain is expected; in fact just in the way which proves most effective in the treatment of regular ague. If after three or four doses a decided improvement is not effected, the probability is great that the Neuralgia is not malarial. Nevertheless, arsenic may subsequently be tried if other means (to be presently described) prove ineffectual.

In a certain number of non-malarial cases, also, quinine produces good effects; but there is no need, nor is it advisable, to employ it in such large doses. From two to three grains, three times a day, is the largest quantity which is likely to be of any use, if my own experience is worth anything. I know of no circumstances which indicate beforehand that quinine will be useful in non-malarial cases, except that it seems always much more effective in Neuralgia of the ophthalmic branches of the fifth, than in other non-malarial Neuralgias.

With regard to other non-malarial Neuralgias I share Valleix's opinion, that it is far from being frequently useful.

Arsenic is a more widely applicable remedy: for it is useful in many cases both of the malarial and of the non-malarial type. In the former, it should be given, probably, in full doses, ten minims, increasing to thirty, of Fowler's solution, three times a day. In the non-malarial forms, the ordinary tonic dose of five minims of Liq. Arsenicalis, three times a day, or $\frac{1}{4}$ grain of Arseniate of soda in pill,
with extract of hop, * will effect all the good which this medicine can produce. The ordinary precautions must of course be observed, as in any other case where we employ arsenic. There is one form of Neuralgia, however, which merits special mention in relation to arsenical treatment; I mean the specially neurotic form of angina pectoris. In France this remedy is extensively used for cardiac Neuralgia. I have myself seen most remarkable relief afforded by arsenic in this complaint, and an extraordinary tolerance of the system to large doses of it. Very recently, Dr. Philipp has put on record a most interesting case of the kind.† There are indeed, some patients whose alimentary canal is too irritable to bear this remedy at all; but it is usually well borne, and often extremely efficacious. Arsenic may also be effectively administered by subcutaneous injection.

The preparations of zinc, and more especially the valerianate, enjoy a high reputation with some practitioners. It is necessary to record this fact; but I cannot say that I have ever seen any good result, which could be confidently attributed to these remedies, in Neuralgia.

(d) Last, among the constitutional remedies, we have to mention those which are directed against a real or presumed deprivation of the blood by some special poison. Neuralgia may certainly arise from syphilis; but then it is probably always due to a local deposit somewhere in the course of the affected nerve. Where this can be suspected, iodide of potassium should be administered in large doses; and if this fails, the bichloride, or biniodide of mercury, in small doses. Neuralgia is said to have frequently a gouty origin: but the facts on which this statement rests, perhaps hardly warrant a decided opinion. They scarcely amount to more than this, that in a certain ill-defined group of cases, the subjects of which are perhaps more often than not of a gouty constitution, a form of Neuralgia occurs which yields more speedily to treatment with colchicum than to any other remedy. Twenty to thirty minims of the tincture or the wine, three times a day, will be sufficient; and if a marked good effect be not produced in two or three days, the medicine should be abandoned, or even earlier, if any tendency to weakness or irregularity of the heart's action be perceived.

"Rheumatic" Neuralgia is a phrase which, under the precautions above indicated, must still be retained, as signifying a class of cases in which inflammation of circumjacent fibrous tissues seems to cause the neuralgic pain by producing mechanical damage to the nerve. Iodide of potassium in five to ten grain doses twice or thrice daily is often useful; causing the absorption of local deposits, or rather of local proliferations of fibrous tissue. Even in cases where the Neuralgia was the primary affection, and the fibrous hypertrophy secondary to it, the local tenderness and swelling appear to be often diminished by the use of this remedy. I have never seen colchicum produce

* Dr. Radcliffe tells me he finds that extract of hop enables arsenic to be better tolerated than when given alone.
the slightest benefit in these cases, in which local tenderness is a prominent symptom.

2. We have now to consider the large group of narcotic-stimulant remedies for Neuralgia. In this class, I include not only the substances generally recognised as belonging to it, such as opium, belladonna, alcohol, &c. &c., but also many others, such as ammonia, turpentine, &c., which are commonly spoken of merely as "stimulants;" and also substances which, like aconite, are ordinarily ranked either as pure "sedatives" or as "acro-narcotics." I shall not retrace here the arguments which I have given at large, in my work on "Stimulants and Narcotics,"* to prove that all these substances possess the common property of assisting nerve function when given in small doses, and of paralysing it when given in excess.

The narcotic-stimulant group of remedies, when administered internally or by subcutaneous injection, may be said to hold an intermediate position between the constitutional and the local agencies which we may employ against Neuralgia. On the one hand, they enter the general circulation, and pervade the organism. On the other hand, it may be suspected that in many cases their effect is produced mainly by a local action, either upon the central nuclei of affected nerves, or perhaps upon their spinal ganglia.

Indisputably, at the head of all this class of remedies stands opium. And we may consider opium, as used against Neuralgia, to be fully represented, for every useful purpose, by morphia. But the gastric administration of opiates can, after all, be only considered as palliative. The invention of the subcutaneous injection (which was imperfectly forestalled by the endermic method,) has thrown quite a new light on the capabilities of opium as an anti-neuralgic. It may be confidently said that in the right use of this remedy, we possess the means of permanently and rapidly curing very many cases, and of alleviating, to a degree quite unknown before, the suffering caused by even the most inveterate forms of Neuralgia.

The local injection of alkaloids, as first systematically employed by Dr. Alexander Wood, is a proceeding which is specially applicable, in my opinion, only to a few cases. In many instances the nature of the integument at or near the point of severest pain, is such as to render the local operation inconvenient or even impossible. In the great majority of cases, especially those which are seen early, the injection may be more advantageously performed in some indifferent place, such as the loose skin over the front of the biceps muscle, or, in fact, in any place where a fold of skin can be conveniently picked up. The substance injected, if properly dissolved in a convenient quantity of fluid, quickly enters the general circulation, and, in a large majority of instances, produces just as decided an effect on the local nerve pain, as if it had been locally injected. I cannot doubt that, in the greater number of cases, the "local" injection is such only in name; the injected substance producing no effect till it has entered.

the absorbent vessels or the veins, and thence travelled all round the circulation to the small arteries, either of the spinal and ganglionic centres, or, perhaps, to the arteries which supply the peripheral branches of nerves. The discovery of the great utility of the plan of general, as opposed to local injection, is due to Mr. Charles Hunter, and is of the highest importance, not merely as a practical fact, but in the suggestions which it gives as to the general subject of the place of origin of Neuralgia. There is, however, a class of cases in which the local injection of morphia becomes desirable. In advanced cases, in which very great local hyperaesthesia exists, and there is reason to think that thickening and hypertrophy of the structures round the nerve has taken place, I have several times known injection at a distant point to fail, when local injection of the same substance, in the same dose, has immediately produced a marked effect; and the same thing has recently been pointed out to me by several medical men. It happens sometimes, however, that in the very cases which seem most to demand the local injection, the local tenderness makes the operation intolerably painful: in such a case I should recommend a plan which Mr. Hart introduced to my notice, viz.: that of first rendering the skin insensible with ether spray, and then injecting. As the freezing process renders the tissues quite hard, a steel cannula to the syringe is needed to penetrate them.

As regards the dose to be employed, I cannot but think that the received ideas are much in fault. One hears constantly of as much as half a grain or one grain, even, of morphia being employed, even at the outset. That such quantities are necessary, sometimes, where the cellular tissue injected into is already irritated and thickened, I have no doubt; and I explain it by the hypothesis that a good deal of the injected substance never enters the general circulation, nor even the vessels of the part, but lies encysted, just as is undoubtedly the case when one injects an irritant substance like pure chloroform into the cellular tissue anywhere. But I am quite certain that when injection of any non-irritant solution of morphia into a healthy cellular tissue is neatly performed, it is unnecessary and even unsafe to commence with larger quantities than \( \frac{1}{8} \) gr. Both in my own practice and in that of a friend, I have known so little as \( \frac{1}{4} \) gr. produce dangerous symptoms of poisoning in a person not especially sensitive to opium; and I am convinced that the activity of remedies hypodermically used is generally much underrated. I have produced all the desired effects by injection of not more than \( \frac{1}{10} \) gr. in slight cases, and very rarely indeed (where the morphia is injected at an indifferent spot) do I increase the dose beyond \( \frac{3}{4} \) gr. The best medium dose is \( \frac{1}{4} \) gr. and the injections should be repeated, if possible, daily, or even twice a day in severe cases. In visceral Neuralgia, it need hardly be said, we are obliged to be contented with injection at an indifferent spot; yet (as e.g. in ovarian neuralgia), we sometimes produce excellent effects.

Next to opium in value, amongst the stimulant narcotics, is belladonna and its alkaloid atropia. The value of belladonna, as given by
NEURALGIA.

749

the stomach, is confined pretty much, according to my experience, to painful affections of the pelvic organs, on the sensory (as notoriously in the motor) nerves, of which it seems to have a special influence. In doses of $\frac{1}{10}$ gr. to $\frac{1}{6}$ gr. of the extract, it will frequently relieve ovarian dysmenorrhoea, as also some forms of superficial lumbo-abdominal Neuralgia. But by far the most important use of belladonna is by the subcutaneous injection of atropia. From the $\frac{1}{10}$ up to the $\frac{1}{6}$ of a grain is about the range of doses for adults; and I can confirm the statements of Mr. Hunter that by repeated applications of this treatment, even very severe and invertebrate Neuralgias are often greatly relieved, and sometimes cured. It is a question whether there is not less tendency to relapse after this treatment than after that by morphia. On the other hand, I have met with more than one person in whom it has been found impossible to give a dose sufficient to relieve the pain without producing distressing head symptoms.

Next in value to morphia and atropia comes Indian hemp, which has been especially brought forward by Dr. Reynolds. A good extract of this, in doses of from $\frac{1}{2}$ to $\frac{1}{2}$ grain (or rarely) 1 grain, given in pill, is very effective in some forms of Neuralgia, particularly in clavus hystericus and migraine. Even in the severest and most intractable forms it often palliates greatly. It should be given every night, whether there be then pain or not.

Muriate of ammonia is an excellent stimulant remedy in migraine and clavus, and in some cases of intercostal neuralgia. It should be given in 10 to 20 gr. doses. In cases of suspected hepatic neuralgia I have also found it very useful; and I believe that its action on the liver (in disorders of secretion) is through the nervous system entirely.

Sulphuric ether, which in the severer forms of superficial neuralgias is of little or no effect, is supremely useful in certain visceral neuralgias. It sometimes relieves gastralgia, and Neuralgia of uterine or ovarian origin, with magical rapidity. But it is still more valuable in the most purely nervous form of angina pectoris. I have now under my care a case of this latter affection, which I am convinced would have ended fatally long since, in one of the agonizing attacks of spasmodic heart-pain, but for the discovery that by taking a spoonful of ether immediately on its commencement, the patient can greatly mitigate the attack. This patient had tried arsenic, but from the irritability of his intestinal canal, could not take it. The same dose of ether has continued to produce the same happy effect on each occasion of its use for the last three years.

Aconite, in the form of Flemming's tincture, is of very great use in some forms of Neuralgia, especially in that kind of ocular neuralgia, with secondary inflammation, which is so frequently called rheumatic iritis. But, unfortunately, it is a very uncertain remedy in one respect: with some persons it produces nausea, burning in the throat, and a sense of cardiac depression, with doses which are quite harmless to other patients. In a case where I recently employed it, in only three minim doses every six hours, I was compelled to abandon
it after the third dose, from the intensely depressing effect which it produced.

The oil of turpentine is a remedy which enjoys, or enjoyed, considerable reputation for its effect in a certain class of cases. In the more obstinate forms of sciatica it is at least worth a trial, although it is commonly very disagreeable to the patient; ten minimis, three times daily, is the proper dose.

Still, after the enumeration of all the narcotic stimulant substances which have been, and many more that might be, named, it would be idle to pretend that any of them are to be compared, for wide and general efficacy, to the subcutaneous use of morphia and atropine, and the internal use of Indian hemp in small doses.

I have reserved to the last, under the head of Stimulant Narcotics, what must be said about alcoholic drinks. There can be no question about the power of alcohol to relieve neuralgic pains; it is as distinct as that of opium. But the dangers of prescribing it as a remedy are very great, since the patients cannot always be induced to use it in the strictly medical manner in which alone it is safe. Too often, instead of employing it in the moderate stimulant doses which really are of service, they accustom themselves to drowning the pain with a large narcotic dose, and they thus contract a liking for the oblivion of drunkenness. It is of much consequence, where this is possible, that they should be forbidden to take alcohol otherwise than at meal times. If once they are induced to take it for the mere relief of acute pain, there is great danger that they will drink to excess. I am, nevertheless, convinced that a fixed daily allowance of wine or brandy (beer more rarely agrees), which shall contain not more than one ounce of absolute alcohol, is a decided help to recovery from every form of Neuralgia; and in the case of persons of firm character, who can be trusted to exercise self-control, a larger quantity than this may sometimes be allowed. Without pretending to speculate on the physiological reason for it, I must add my testimony to the fact, which has been observed by Dr. Radcliffe, that saccharine liquors and saccharine foods, except in very moderate quantities, decidedly disagree with neuralgic patients.

3. We come now to consider the external remedies for Neuralgia. Incomparably the most valuable of these is the use of so-called counter-irritation; that is, the application of various irritants to the skin. Valleix comes to the conclusion that there is no one remedy which approaches blistering in value, and (putting aside the recently discovered hypodermic treatment) that saying remains absolutely true at the present day. It is to be observed that Valleix latterly always employed the milder form of the flying blister. Such an application as this to the foci of pain must, if we consider it, be supposed to excite a directly stimulant effect upon the painful nerve. This kind of blistering, and the analogous use of mustard plasters, have always yielded good results, in my experience, solacing even when they did not cure. And in numerous early cases one or two flying
blisters, applied successively over different points in the course of the painful nerve, have at once and permanently arrested the disease. It is a remedy which ought always to be tried in cases of any severity, especially if the subcutaneous injection of morphia and of atropine has failed. There is one method of blistering which I have recently tried with great success, viz. the application of a blister close to the spine, as nearly as possible opposite the intervertebral foramen from which the affected nerve issues. The effect produced is, I suppose, a reflex stimulation through the posterior branches. This method is of course not so applicable to Neuralgias of the fifth as to those of spinal nerves. Yet even in these, blistering of the nape has sometimes appeared to do marked good—through the occipital nerve, I presume.

The application of various stimulating liniments and ointments to the skin of the painful parts is sometimes very useful. Of these the use of chloroform diluted with seven parts of oil or soap liniment is far the most efficacious. This produces no anaesthesia, but a mild stimulation. Strong counter-irritation may be produced by the use of tartar-emetic or of Veratrine ointment.

Electricity.—The efficacy of various forms of electricity in Neuralgia is a large subject, and as yet, it must be owned, only very partially cleared up. The comparative merits of Faradisation and of the continuous current are hardly settled. But the weight of testimony is now in favour of the belief that in the majority of instances the continuous current is the most valuable.

As regards one or two points, one may speak with some confidence. In the first place I may say, after extensive trials of the ordinary rotatory (magneto-electric) machine for the induced current, that this method of treatment is most unsatisfactory. I have never seen it produce, indisputably, good effects. Secondly, as regards that form of continuous current which is generated by Pulvermacher's chains, I am reluctantly obliged to give up the hope of doing any real service with it in Neuralgia, however great its utility is in other diseases. As is remarked by Dr. Althaus, the current generated by these chains is too irregular, and their activity is too soon exhausted for us to get a sufficiently uniform dose of electricity applied continuously for a definite period by their means.

It appears probable that we shall ultimately find that for neuralgic affections of all kinds the most useful form of electrical treatment is by the continuous current generated from a Bunsen's or a Daniell's battery; and that the three principles on which we must act in its use, are:—1. The maintenance of the current, with only a very few breaks, for a considerable time. 2. The application of the positive pole over the seat of pain. 3. The employment of a very low-tension current. I am informed by Mr. J. N. Radcliffe, whose experience in this matter is very large, that the use of this mode of electrization in Neuralgia is as yet, in his opinion, only beginning to be developed, but that it promises to effect great things. In short, my present opinion as to the value of electricity in Neuralgia.
may be thus expressed: that as used, up to the present time, it has achieved no results which entitle it to more than a third or a fourth-rate place among remedies; but that if the desideratum of a low-tension continuous current, which can be readily applied for long periods together, can be obtained by means of apparatus of moderate portability and cheapness, it is probable that we may obtain that which will equal or exceed in value any of the remedial measures which are at our disposal.

A few words must be given to the rather uninviting subject of the surgical treatment of inveterate Neuralgia. The section of a neuralgic nerve, or rather the excision of a piece, is still, I suppose, to be reckoned among the measures which it may be occasionally justifiable to employ. Nothing, however, either in the two cases of its use which I have seen, or in the records of similar operations, would lead me to recommend it in any case. The relief given is nearly always very transient; and, indeed, the nearly infallible certainty with which the pain returns in the central end of the divided nerve is only what I should expect from the many considerations which point to the central origin of the nerve as the most peccant part. With such remedies in our hands as the subcutaneous injection of morphia, &c. I cannot see that we need be tempted to perform such an operation for the sake of a temporary alleviation.

The removal of any distinct source of peripheral irritation by surgical means is quite another matter, and may be highly proper and necessary. Yet even here it is always necessary to calculate whether the shock of the procedure itself may not be injurious; and it will be desirable before inflicting it to fortify the system, as far as possible, with tonics; and sometimes to diminish the shock, not merely by giving chloroform, but by prolonging the chloroform narcosis by subcutaneous injection of a large dose of morphia. This precaution is especially advisable where we extract one or more carious teeth, which may seem to be keeping up neuralgic pain. Too often we find that the extraction has been in vain; and then, unless some such precautions have been taken, it may be discovered that the shock has aggravated the Neuralgia.

A most important subject, with which I may conclude these remarks on treatment, is the employment of suitable prophylactic measures. First, as regards nutrition; it is absolutely necessary that this should be as abundant as may be possible without deranging the digestion. It must also contain a liberal allowance of fatty matters; no amount of dislike on the patient's part—and they often show great dislike—should induce the physician to give up this point. If one form of fat cannot be tolerated another must be tried; perseverance will, I believe, always bring success; and the effect of an improvement of this kind in the diet will rarely fail to tell upon the constitution, rendering the nervous system less sensitive to the ordinary exciting causes of neuralgic pain. Equally important is the avoidance of exposure to cold and damp air with insufficient clothing, for cold is
much the most frequent immediately determining cause of neuralgic attacks. Flannel under-clothing, thick veils for the face, &c., are quite as important as any direct remedies. It cannot be doubted that everything which tends to set up the habit of pain, directly tends also to aggravate that obscure vice of the organism on which the disposition to Neuralgia depends, and vice versa. Physical exercise must be so regulated that it may improve nutrition without inflicting severe fatigue. And as regards mental influences, which, unfortunately, are often beyond control, one can only say, that the two extremes, of a specially laborious and exciting life, and an existence spent in the dreary monotony of idleness, are equally hurtful.

In the foregoing article I have followed the plan also adopted in my article on Alcoholism; namely, of stating my own view of the subject connectedly, and without pausing to answer all the statements and opinions of the numerous writers who differ from me. The necessary limits of a work like this "System of Medicine," makes it almost impracticable for an author to follow any other course with success, if he happens to hold a view of his subject which conflicts with, or differs from, the view of well-known authors on a considerable number of points. But the following selected list of the more important treatises will enable the reader to study the questions connected with this disease from every point of view. It has been my purpose to bring out clearly and consistently that view of Neuralgia which seems warranted by the majority of the facts recorded by others or observed by myself; and the result has been that I have given much prominence to the arguments for the existence of an element of organic change in the centres in all true Neuralgias. Those who desire, however, to hear all the arguments which can be urged for a chiefly or solely peripheral origin of Neuralgia will find abundant material in the undermentioned treatises: Trouseau, "Névralgie Epileptiforme," vol. i. of his "Clinique Médicale," 2me Edit.; "Névralgies," vol. ii. of the same work. (Trouseau's insistence on the constant presence of a painful "point apophysaire," seems to me an overstatement; but it is still more strange that this author should think its constant presence could consist with a peripheral origin of Neuralgia.) Bean, Traité des Névralgies, Arch. de Méd. 1847. Brown-Séquard, Lectures on the Therapeutics of Nervous Diseases. Lancet, 1866, vol. i. See also his Lectures on the Physiology and Pathology of the Central Nervous System, 5vo. Philadelphia, 1860. Of authors who allow at least a large share in the production of many cases of Neuralgia to the centres, are Teale, Treatise on Neuralgic Diseases, &c. London, 1829. C. Handfield Jones, on Functional Nervous Disorders, London, 1864; also Lumleian Lectures, Med. Times and Gaz. 1865, vol. ii. But the most suggestive and important treatise, and one which has been unaccountably neglected, is the Observations on the Functional Affections of the Spinal Cord, by William and Daniel Griffin, London, 1834. I have, in the text, given Valleix just credit for laying the foundation of the current knowledge respecting Neuralgia; but it must be allowed that in the work of the Griffins, which is little known, there are the germs of a great improvement of that knowledge. Of essays which illustrate the serious secondary complications which may attend Neuralgia, the following may be mentioned, besides the treatises of Barenbrug, of Notta, the work of the Griffins, and other papers already specified,—Schiff, Hyperaemia of the Eye, Ulceration of Cornea, &c. after a Wound of the Superior Maxillary Nerve; Untersich, p. 116. Alcock, Disease of the Eye from injury to the Infra-orbital Nerve. Todd's Cyc. of Anat. and Physiology, vol. ii. p. 132. A great many cases also are quoted in Handfield Jones's Lectures on Functional Nervous Disorders, already cited.

It is only just to Dr. Handfield Jones to acknowledge that he has long advocated the opinion that nerve-pain is invariably, and in all its phases and consequences, an expression of debility of function; an opinion which has been strongly expressed also by myself not only in the present article, but in many other papers.
LOCAL PARALYSIS FROM NERVE DISEASE.

By J. Warburton Begbie, M.D., F.R.C.P.E.

There can be no doubt that for a lengthened period, and till a comparatively recent date, the attention of pathologists was too exclusively directed to the great nervous centres in explanation of the causes of nearly all nervous disorders, including paralysis. So much so was this the case as fully to justify the language employed by the late Dr. Graves, of Dublin. "If," says he, "you examine the works of Rostan, Lallemand, Abercrombie, and those who have written on diseases of the nervous system you will find that their inquiries consist in searching after the causes of functional changes, either in the cerebrum, cerebellum, or spinal marrow, forgetting that these causes may be also resident in the nervous cords themselves or their extremities, which I shall call their circumferential tracts."* Since 1843, however, when the first edition of Graves's lectures appeared, it has been satisfactorily determined by physiological investigation and by the careful observation of disease in numerous examples, that paralysis, or the loss of the power of motion, may result from one or other of two causes. It may depend either on a central nervous lesion, that is, a lesion of the Brain or Spinal Cord, or on an abnormal condition of a particular nerve in some part of its course. It is with the latter, as giving rise to a local form of paralysis, that we are now exclusively concerned. We are abundantly familiar with the effects of mechanical injury as applied to nerves. When a nerve is cut across there results immediately a paralysis of the parts below the section supplied by that nerve. Further, if a nerve be included in a ligature, or subjected from any cause to much pressure, a similar result is produced. The paralysis of the arm caused by pressure on the axillary plexus of nerves, is an excellent and familiar illustration of injury so occasioned. It is thus described by Dr. Todd:—"A man gets intoxicated, and falls asleep with his arm over the back of a chair; his sleep under the influence of his potations is so heavy, that he is not roused by any feelings of pain or uneasiness, and when at length he awakes, perhaps at the expiration of some hours, he finds the arm benumbed and paralysed. It generally happens that the sensibility is restored after a short time, but the palsy of motion continues. Cases of this kind sometimes derive benefit from galvanism, but if the pressure which caused the paralysis has been very long

* Clinical Lectures on the Practice of Medicine, Lecture xxxiii.
continued, they seldom come to a favourable termination. Nerve-tissue is one which never regenerates quickly, and seldom completely, so that great or long-continued lesion of its structure is not likely to be removed.* Although by no means so distinctly witnessed as the result is, in the class of cases now referred to, there seems no reason to doubt that, equally with mechanical injury, interference with the proper nutrition of nerves may lead to forms of local palsy. Illustrations of such occurrences will be adduced, more especially when directing attention to one of the most interesting of all the varieties of local paralysis, namely facial palsy. Again, familiar as we are with the action of various poisons, such as alcohol, opium, chloroform, on the great nervous centres, and on the same portions of the nervous system of certain poisons formed in the living body, as urea, and the morbid materials in rheumatism and gout; having also important knowledge regarding the influence which is exerted on the nervous and muscular systems generally, but especially on the nerves and muscles of the upper extremities by the poison of lead, we cannot hesitate to account, in a manner closely similar, for the other forms of local paralysis which from time to time present themselves to our notice.

Dr. Todd alludes to cases of local paralysis occurring in states of the constitution which, if not rheumatic, are at least allied to it, and associated with imperfect action of the kidneys. "Of this," he says, "the following affords a good example:—A medical man, etat. 53, extensively engaged in practice in the county of Bucks, applied to me in August, 1847, with complete paralysis of the deltoid muscle. He was a stout, full man, tall, of large build, and very active in his habits; fed well, and drank beer, but not to excess. He had been subject to a shifting neuralgia of the scalp, and to a discharge from the right ear, where he thought the tympanic membrane was destroyed; he was deaf on that side. Six weeks before he came to me he suffered from pain in the left side of the neck and shoulders, followed by complete paralysis of the left deltoid muscle and weakness of the whole arm. On examining, I found a total inability to raise the left arm to a right angle with the trunk, or to perform any of those actions which are usually effected by the deltoid muscle, which was very much wasted. He could, however, grasp perfectly with the left hand, and execute all the other movements of the arm and forearm. There was some degree of numbness of the arm. There were no symptoms distinctly referable to the head. His tongue was coated; appetite good; the discharge from the ear had ceased. The urine was pale, of low specific gravity, and contained albumen in small quantity. I viewed the case as one of local palsy, connected with a deranged state of system, rheumatic or gouty. I regulated his diet, and gave him small doses of the mineral acids. After a fortnight of this treatment he improved considerably, and could raise his arm slightly. The albumen in the urine had much diminished: and crystals of lithic acid were precipitated. He was

* Clinical Lectures on Paralysis, certain diseases of the Brain, and other affections of the Nervous System, Lecture 1.
now ordered three grains of iodide of potassium, with ten minims of liquor potasse thrice daily. He only followed this treatment for ten days, as the iodide of potassium purged him. Still, he was improving. I continued the liquor potasse, and advised galvanism to the muscle. This plan was diligently pursued for a fortnight, at the end of which time he had so far improved that he could raise his arm nearly to a right angle, he could put on his coat, and tie his cravat; and in three weeks more he was quite well. All signs of albumen had disappeared from his urine."* The writer's experience has furnished cases bearing a remarkable resemblance to the one now quoted. He calls to remembrance more especially that of a young and plethoric as well as highly rheumatic female, who suffered from paralysis, succeeding severe pains of the left lower extremity, and in whom a plan of treatment which secured the copious discharge of urine, previously much diminished as well as disordered, and free action of the skin, proved eminently successful in removing the palsy of the limb. Besides the gouty and rheumatic poisons, it is well to keep in view the very decided action of the syphilitic in inducing this among other local disorders. No one calls in question the injurious effects which are capable of being produced on the nervous centres by the syphilitic poison; there is, however, good reason to believe that some local palsies are thus created. The writer has been able to trace the occurrence of paralysis of the porcio-dura, of paralysis of the third pair, as shown by a marked ptosis; and also of palsy of the limbs, slight although threatening, to the same cause, when neither brain nor spinal cord appeared to be implicated. And it is probable that the experience of many physicians has not been dissimilar to his own, in finding the iodide of potassium administered in large doses, and steadily persevered with, a most useful remedy in such cases, relieving the palsy as effectually, as it is so frequently the means of doing, the neuralgic and wearing-out headache, or the painful node on the shin bone, which are evidently due to the same cause. Allusion has been made to the influence of direct pressure external to the body, in producing such injury of nervous structure as leads to a form of local paralysis. Palsy thus induced is generally merely temporary in duration. Tumours within the body, involving nerves, are frequently the direct occasion of local palsies. No more interesting variety of such palsy exists than that which is due to the interference with the recurrent or motor laryngeal nerve produced by an aneurism of the arch of the aorta, or by a cancerous mediastinal tumour. Well marked atrophy of the muscles of one side of the larynx has under such circumstances been found. The dyspnœa, which is induced by the implication of the vagus, or as sometimes happens of the phrenic nerves in strumous or tubercular tumours, is abundantly recognised since the writings of Risberg and Ley. There seems reason to believe likewise that pressure upon or other injury of some parts of the sympathetic nervous system may occasion local palsies. Of this the paralysis of the radiating fibres of the iris caused by cutting the sym-

* Loc. cit. p. 72.
pathetic in the neck in Budge and Waller's experiments, but especially
a similar contraction of the pupil to that physiologically produced, due
to the pressure of an aneurism projecting into the neck or malignant
tumour similarly situated, are now quite familiar to the physician.

Attention will now be directed to some of the more important
varieties of local palsy dependent on nerve disease, and first to Facial
Palsy. This most interesting local paralysis is known under different
names, of which the more commonly employed are Facial Hemiplegia,
Histrionic Paralysis, Bell's Palsy, and Paralysis of the Portio-dura.
Occurring as it usually does on one side of the face only, nothing can be
more striking than the peculiar features of the disease. This is owing
to the palsied condition of a few or all of the superficial muscles—the
muscles of expression—on the affected side, and the heightened anta-
gonism of muscular action on the unaffected side. The patient cannot
knit the forehead,* neither can the eyebrows be raised or drawn
together. The eye remains open, as the power of closing the lids is lost,
and their blinking movement no longer exists. This open condition of
the eye, seen both in waking and sleeping, and which is due rather to the
increased action of the levator palpebræ muscle, than to the palsy of
the orbicularis palpebrarum, is a characteristic, it has indeed been styled
a pathognomonic feature of facial palsy.† The ala nasi is dependent,
and on full inspiration on smelling or blowing the nostrils there is no
expansive movement. The angle of the mouth hangs down. Further,
the patient cannot whistle, for he is unable to purse up his mouth for
that purpose, and for the same reason he can neither spit, nor can he
distend the buccal cavity with air, or blow wind from the mouth.

Pronunciation of labials is notably impaired. The saliva and fluids
frequently trickle from the mouth. In mastication portions of food are
apt to collect between the cheek and gums, as the support of the lips
and cheeks necessary for its proper performance is lost. Let the
patient laugh, cry, sneeze, yawn, or be the subject of any violent
emotion, and the distortion of the features becomes much more con-
spicuous, the face being forcibly drawn to the sound side. Motionless
and void of expression is the one side, contrasting in a very remarkable
manner with that on which intelligence remains visible and power of
movement unaltered. Trickling of the tears down the cheek, owing to
the immobility of the lower eyelid, with consequent dryness of the
 corresponding nostril, and redness of the conjunctiva, it may even be
severe conjunctivitis, determined by the operation of cold, dust, or
other external influences on the constantly exposed eye, are among the
accompanying phenomena of this palsy.

* In alluding to the smoothness of the brow in the aged, who are affected by facial
palsy, owing to the disappearance of all wrinkles, Romberg facetiously observes, "für
alte Frauen kein wirksameres Cosmeticum existirt."
† "The leading character of cases of facial palsy,” writes Dr. Todd, "is the inability
to close the eyelids, from paralysis of the orbicularis palpebrarum; this is the pathogno-
momonic sign which determines the peculiar nature of the palsy, and distinguishes it from
the most serious form of facial palsy, which is dependent on disease of the brain and
palsy of the fifth or third nerve." (Clinical Lectures, Lecture iv.)
To Sir Charles Bell we are indebted for pointing out the true nature of this affection. He showed that one nerve only was involved, that the muscles governed by the portio-dura of the seventh pair were alone affected, that strictly it is a local palsy. The sensibility of the face is usually unimpaired; a slight affection of the filaments of the fifth may, however, cause a little facial pain, but that is to be accounted rare. In instances of long standing facial palsy, Romberg has drawn attention to the relaxed and flaccid condition of the skin covering the affected muscles, while Dr. Todd has insisted on increasing flaccidity of the cheek, and especially a rapid development of that condition, as a symptom of unfavourable omen as regards the patient’s prospects of recovery. But while this form of local palsy is clearly dependent on lesion of one nerve only, there is reason to believe, as Romberg has more particularly shown, that its features are subject to modification, according to the precise seat of the disease. That may be peripheral or central. Not only so, but the diagnostic marks may vary under the former head, according as the superficial distribution of the portio-dura, or the nerve as it passes through the temporal bone, or the nerve within the cranium and near its central origin, is affected. Viewing these very briefly in their order, it may be remarked—that, facial palsy, due to an affection of the superficial distribution of the nerve, is generally met with as the result of exposure to cold.* "A very common cause of this palsy," writes Dr. Todd, "is the influence of cold; as by exposure at an open window, in a coach or railway carriage, to a current of cold air.” † "A blast of cold air on one side of the face," remarks Dr. Graves, "has been known to cause paralysis and distortion of several months’ duration." ‡ External injuries, such as blows on the cheek, and surgical operations on the face, have been followed by this form of local palsy. Of the cases which occur, there are not a few in which no traumatic cause can be found, neither can any marked exposure to cold be traced. In such circumstances it is proper to make a very careful inquiry into the condition of general health of the sufferer, when, it is not unlikely that the connexion of the palsy with a gouty or rheumatic taint may be satisfactorily established. Dr. Todd, alluding to the dependence of periodical neuralgic affections on the determination of some poison to a particular nerve, as the paludal poison or some matter generated in the system, expresses the opinion that morbid matters may affect a motor nerve just as they affect a sensitive, causing in the former case paralysis, as in the latter they determine neuralgia.

Facial Palsy caused by an affection of the portio-dura in its passage through the temporal bone.—The connexion of this paralysis with

* Some writers speak of facial palsy as specially a disease of northern climates. Thus Joseph Frank, after alluding to the collection of cases by various authors, remarks, "Nasque plurima exempla vidimus. Morbus iste in regionibus septentrionalibus tam communis est ut spatio quindecim annorum viginti duo mihi obvenerint exempla." (De Paralysis, Praxeos Medicæ Universæ Precepta.)
† Loc. cit. p. 69.
‡ Loc. cit. p. 380.
local strumous affections in children is well known. These may be simple and easily remediable, as for example the parotid and more general glandular enlargements consequent on measles, scarlatina and other disorders; but of much more serious nature is the otitis resulting in caries of the petrous portion of the temporal bone. Here the palsy is associated with deafness, and very probably also with purulent discharge from the meatus. Direct violence, likewise, as in a case related by Sir Charles Bell, in which a pistol shot through the ear had splintered the bone, and torn the nerve in its osseous canal, may of course determine the palsy. The diagnosis of the disease or injury affecting the nerve, in its passage through the bone, rests, according to Romberg, not only on the co-existence of such phenomena as otorrhoea, removal of necrosed portions of bone, perhaps of one or other of the small bones of the ear, and deafness,—symptoms which are not likely to occur in cases of simple peripheral facial palsy, but, further, upon certain peculiarities in the observed paralytic phenomena. One of these is the diminution of taste on the side of the tongue corresponding to the palsy, another is a unilateral paralysis of the velum palati. On the latter point the statements of writers have been very contradictory. Romberg remarks that in four patients afflicted with facial palsy he has noticed the paralysed condition of the velum palati, the uvula, having a slanting direction, being arched and the tip pointed to the paralysed side. While failing to offer any explanation of the peculiar position of the uvula, Romberg evidently attaches very great importance, in a diagnostic point of view, to the palsied condition of the velum, and the marked curving of the uvula; concluding, from their existence, that the seat of the disease must be in the petrous portion of the temporal bone. And he again emphatically repeats when the disease is in the peripheral distribution of the nerve, the velum is not affected, "wovon ich mich in vielen Fällen überzeugt habe." It is the implication in the diseased condition, of whatever nature that may be, of the nervus petrosus superficialis major, of Arnold—which taking its origin from the knee-shaped bulb on the trunk of the portio-dura as it lies in the Fallopian aqueduct, and which communicates with Meckel's ganglion, whence the muscles of the palate derive their nerves,—that in the view of Romberg causes the displacement of the velum and uvula. Dr. Todd, while admitting the occasional occurrence of this phenomenon, combats the notion of Romberg, and maintains that undoubted instances of disease of the aqueduct, causing paralysis of the nerve, are met with, in which affection of the velum does not exist. In his own experience the symptom in question was of very rare occurrence, and he regarded it as a coincidence. Since the publication of the views of the authors now referred to, the paralysis of the palate in facial palsy has received renewed attention from M. Davaine and Dr. Sanders. The former recorded one case of unilateral paralysis of the palate, in connexion with facial palsy of right side, observed by himself, and has commented on several instances furnished by Romberg and others. His
description of the phenomena he observed is given as follows:—"The velum palati is not regular; the arch formed by the right anterior pillar is less elevated than the left. The posterior pillar of the same side descends directly downwards, without being curved like that of the other side. The uvula is bent like a bow; its point is directed forwards and towards the paralysed side, while its base is carried a little towards the sound side. The patient's voice is slightly nasal." *

Dr. Sanders, in a valuable paper,† gives an interesting case of paralysis of the velum in connexion with facial palsy of the right side, and enters at some length into a consideration of the mechanism of the deviation of the palate. Dr. Sanders is satisfied that a partial hemiplegia of the palate does exist in connexion with facial palsy, and, like it, is dependent on affection of the portio-dura. He believes that this form of palatal palsy consists in a vertical relaxation or lowering of the corresponding half of the velum palati, with diminished height and curvature of the posterior palatine arch, on the paralysed side, and that it is due to paralysis of the levator palati,—that muscle and the azygos uvula, also supplied by the seventh pair, being the only muscles affected. Among several conclusions at which Dr. Sanders has arrived, the following appear to be specially important; that the partial paralysis of the velum in facial palsy, due to implication of the levator palati muscle, is by no means so rare as palsy of the velum (hitherto not accurately described) has been generally supposed; and that the prognosis is not necessarily rendered more unfavourable in facial palsy when the palate is implicated.

The lesion in facial palsy may exist at the cerebral origin of the seventh pair of nerves. We are not, however, called upon to consider this variety of facial palsy: suffice it to say, that its existence may be determined, and the differential diagnosis, between it and the other forms—already briefly considered—established, by the occurrence, sooner or later, of symptoms due to the implication of other nerves, such as deafness, strabismus, ptosis, and anaesthesia. While, either the presence of inflammatory products, or apoplectic extravasations in the vicinity of the pons varolii may be the precise lesion which gives rise to the palsy, the probability is that, in such cases, a tumour of one nature or other, and subject to gradual extension, exists.

The duration of Facial Palsy is subject to considerable variety according to the precise seat and nature of its determining lesion. Dr. Todd remarks that "it rarely, if ever, lasts a shorter time than ten days, whilst it very often extends to as many weeks; perhaps three or four weeks may be assigned as an average duration for the non-traumatic cases;" and Romberg warns us not to expect its duration to be brief. It is in those cases which have been evidently connected with rheumatism that he has found the paralysis least enduring:‡

* Gazette Médicale de Paris. 1852.
† Edinburgh Medical Journal, August, 1865.
‡ "Die Dauer der nümschen Gesichtslähmung ist selten kurz. Am kürzesten fand ich sie bei der rheumatischen: doch habe ich sie auch hier in günstigen Fällen nur selten
The writer has seen simple cases of the disease, in so far as their cause was concerned, lasting a very lengthened period, many months, and even a year.

It is incumbent on the physician to be very careful in offering an opinion as to the prognosis in cases of facial palsy: that must always be founded on a consideration of the probable cause. Those cases are nearly certain to terminate favourably in which cold or rheumatism are to be looked upon as the determining agents. On the other hand, when the palsy has been due to mechanical injury the prognosis cannot be favourable, and this very specially in those instances where a division of the nerve has been caused. We cannot be too careful in the expression of our opinion in cases characterised by nerve disease within the temporal bone. The records of medicine contain reports of such, which have given rise to meningeal inflammation, intracranial, even cerebral and cerebellar abscess and death.

If prognosis is to be guided by a just consideration of the causes, so also is the treatment of facial palsy when amenable to cure. The remedial measures at our disposal may be conveniently classed under the heads of internal and external agents. In the use of the former, regard should always be had to the diathetic condition of the patients, rheumatic, gouty, strumous, syphilitic, anaemic, or suffering from the injurious influence of a paludal poison. We are disposed to think that this is one of the forms of local palsies in which the loss of power may be due to changes in nerve structure determined by neuritis. In such examples, and still more so, if there be reason to conclude that a syphilitic taint is in existence, iodide of potassium will prove a most serviceable remedy. We have ourselves found it to be so. The iodide should be administered in doses of five grains twice or thrice daily, simply dissolved in distilled water. The efficacy of the remedy is secured by its being administered while the stomach is empty, but food may be taken very shortly thereafter. Should a rheumatic or gouty habit be found in connexion with the palsy, alkaline remedies, colchicum, and lemon-juice, may exert a beneficial influence, and so probably will quinine or arsenic in the not unknown examples of the disease allied to intermittent fevers. Mercury in the form of blue pill has been extolled by several practitioners. Sir Thomas Watson counsels the exhibition of mercury "so as just to touch the gums," adding, "I should always take this precaution, lest any effusion of lymph should cause abiding pressure on the nerve."* Iron is likely to be useful when an anaemic condition of the system exists. The muriate of lime, the iodide of iron, and cod-liver oil, are available remedies when a strumous cachexia obtains. The writer can bear a decided testimony to the therapeutic value of strychnine as an internal remedy in one long-existing instance of the disease, which had bid defiance to the more

* Lectures, vol. i. p. 563.
ordinary remedies; he cannot, therefore, coincide in the observation of Dr. Todd, that "Strychnine is of no use in such cases."

As to external remedies. Blisters, strongly recommended by some physicians, are discountenanced by others, on the ground that they sometimes cause enlargement of the neighbouring glands, which by pressure may in their turn injuriously influence the nerve twigs. Local hot fomentations and the application of leeches are very useful remedies at an early period of the disease, the employment of the latter being generally limited to persons of full habit, and otherwise in the enjoyment of fair health. The endermical application of strychnine—over a blistered surface—the use of various stimulating liniments, and particularly, in the writer's opinion, galvanism, are the more approved remedies in cases which have lasted for a little time.

Before concluding our notice of facial palsy, we must add a few remarks on the occasional occurrence of the disease on both sides of the face, and very briefly refer to the statements of Dr. Todd respecting the integrity of the seventh pair in cases of cerebral hemiplegia, a view which has recently been ably controverted by Dr. Sanders.

Double Facial Paralysis.—This is unquestionably a rare affection, and especially rare when the double palsy is solely dependent on nerve disease. Romberg and Dr. Christison* refer to cases of what may be styled simple bilateral paralysis of the face, while the seventeenth case in Dr. Todd's lectures is a very remarkable example of paralysis of the portio-dura on both sides connected with affection of the portio-mollis; for the patient was "perfectly deaf in both ears;" and the loss of function of both branches of the seventh pair evidently resulted from disease in the temporal bone. In addition to the writers already named, M. Davaine has especially directed attention to the subject in a valuable memoir, the title of which is given below;† and to which Professor Gairdner,‡ of Glasgow, in giving an account of a very interesting case of double facial palsy, has referred. Dr. Gairdner considered the paralysis to be due to cold, and connected with rheumatism of the external branches alone; and in the course of his paper he alludes to another case of double paralysis of the portio-dura evidently connected with syphilis. In the latter case iodide of potassium, with iodide of mercury and corrosive sublimate, were employed in alternate doses, and the result was an excellent recovery. One example of double facial palsy has occurred under the writer's observation; it was associated with tubercular disease within the chest, and the patient, a man of thirty years of age, subsequently died of what appeared to be strumous meningitis. Unfortunately an examination of the body after death was not permitted. This is scarcely the opportunity for

* Monthly Journal of Medical Science, 1850.

‡ Clinical Observations, Lancet, May 18, 1861.
entering on a consideration of the view which was so strongly entertained and expressed by the late Dr. Todd, that the seventh nerve was very rarely involved in facial palsy depending on cerebral disease, and that the affected facial muscles were those governed by the fifth pair. It will, however, tend to complete the brief exposition of facial paralysis now given, if we state in this connexion, that there is, in our opinion, no reason to doubt that the view taken by Dr. Todd, and in which several systematic writers in this country have closely followed him, is erroneous, and that, on the other hand, the current doctrine on the Continent, and which has been recently ably unfolded and extended by Dr. Sanders, is correct; viz. "that in cerebral hemiplegia, as in peripheral face-palsy, it is the motor seventh nerve which is affected." *

Disease of other of the motor cerebral nerves than the portio-dura may likewise determine local palsy. A short reference to such may be made here.

Paralysis due to disease of the third pair of nerves. (Oculo motor.) Ptosis or blepharoplegia, the falling down of the upper eyelid, is the notable feature of this affection. When this is due to a cause seated within the cranium, such as an inflammatory exudation, or a tumour, it is almost invariably accompanied by palsy of those muscles of the eyeball, and those fibres of the iris which are likewise governed by the motor oculi. Hence in such cases, and they are far from being uncommon, external squint and dilatation of the pupil are associated with the ptosis. Not only so, but other adjacent cerebral nerves are for the most part implicated, while the indications of the existence of some formidable cerebral lesion are under such circumstances not likely to be absent. On the other hand, when the determining cause of the local paralysis is peripheral in its seat, the ptosis exists alone. Romberg remarks that rheumatism may be the cause of paralysing the palpebral branch of the motor oculi, although not so frequently as is the case with the facial nerve; and he distinctly states that when so induced, the ptosis occurs without the participation of the muscles of the eyeball, and the contractile fibres of the iris.† The writer remembers to have seen this dependence of ptosis on rheumatism illustrated in the case of a young lady, who after having frequently suffered from distinct rheumatic affections, became within a limited period the subject of facial palsy and ptosis, the immediate peripheral impression on both the seventh and third nerves being evidently due to severe cold. A complete and speedy recovery occurred after the local application of warmth and the use of anti-rheumatic remedies. M. Marchal de Calvi has directed attention to the occurrence of oculo-motor paralysis, con-

* On Facial Hemiplegia and Paralysis of the Facial Nerve, by Wm. R. Sanders, M.D. Lancet, 1865. See on the same subject Dr. Hugglings Jackou in Clinical Lectures and Reports of the London Hospital, 1864.

† "Der rheumatische Anlass paralysirt, obgleich nicht in solcher Frequenz wie'den Facialis, den Ramus palpebralis des Oculomotorius und hat eine einfache Blepharoplegie ohne Theilnahme der Augenmuskeln und der contractilen Irisfasern, nach der Norm der isolirten Leitung, zur Folge." (Augenmarkellähmung.)
sequent on very severe tic of the face. M. Marchal, and likewise the late M. Jobert de Lamballe, found the muscles of the eyeball affected as well as dilatation of the pupil; the vision* disordered, and insensitivity of the conjunctiva in this affection. Such cases, however, are rather illustrative of the reflex form of paralysis, our knowledge of which has been of late greatly increased by the observations of M. Brown Séquard and others.

In the same way as peripheral affection of the oculo motor nerve exists, so may local paralysis result from disease of the *fourth pair* (trochlear), and of the *sixth pair* (abducens). Such are, however, much less frequent in their occurrence, and specially so, as Romberg has observed, that resulting from affection of the abducens. The author just named has made reference to a case seen by Dr. Dahling, and published by Stromeyer, in which the facial and abducens nerves on the left side were paralysed in consequence of a sudden cooling of the heated face.

*Palsy of the tongue* from affection of the hypoglossus nerve in its distribution is of great rarity, offering a marked contrast to the frequency with which a central lesion gives rise to the same form of local palsy.

*The lesser branch of the fifth pair* may be the seat of disease, and consequently give rise to masticatory palsy. The movements of the face in mastication on one or on both sides, as the case may be, are thus arrested or impeded. The temporal and masseter muscles are readily recognised to be inactive; and their condition when the disease is unilateral offers to the touch a marked contrast with the firmness of the same muscles on the unaffected side during the process of mastication. This variety of local palsy, when due to disease of the nerve, is generally caused by tumour of the dura mater, or disease of the sphenoid bone, or such a morbid condition of the Casserian ganglion as compresses the nerve itself.

LOCAL SPASMS.

BY J. WARBURTON BEGBIE, M.D., F.R.C.P.E.

The term Spasm (spasmus, from σπάω, I draw) is used to indicate the sudden and involuntary contraction of muscular fibres or of muscles. Hyperkinesis (ὑπερ, in excess, κίνησις, motion) is likewise employed in a sense precisely similar. This peculiar vital phenomenon may be general or local, involving apparently all, or nearly all, the muscles of the body, or, on the other hand, limited to a few muscles, it may be, to one.

In every occurrence of Spasm there is increased action of the motor nerve, the result of which is the sudden contraction of muscular fibres, the act itself being wholly removed from the control of the will. The expressions clonic and tonic are used, the former to denote a Spasm which is characterized by rapidly alternating contraction and relaxation of muscular fibres, while the latter implies the existence of the contractions for a certain time, and of this condition rigidity of the affected muscles is also an invariable feature.

Attention is now to be directed to local as distinguished from general or universal spasms. To the latter, the term convulsions is correctly applied.

Local Spasm is not necessarily attended by pain, but it generally is so, and as expressive of painful Spasm we find a suitable term in cramp (Saxon kramp). The term cramp is most frequently applied to painful muscular contraction in the extremities, and to the same phenomenon affecting the stomach or intestines, and also the heart. Such pain as occurs in connexion with Local Spasm is in all probability due to injury done to the sensory nerves supplying the muscle during its violent contraction.

Both kinds of muscular fibre, both orders of muscles, the voluntary and involuntary, are liable to be affected by Spasm. Of the former the most familiar illustration is cramp in the extremities. Of the latter are cardiac and intestinal Spasms. Romberg has pointed out that, as a general rule, when the muscles of animal life, those under the control of the cerebro-spinal nerves, are affected by Spasm, the fibres exhibit a uniform contraction throughout their whole extent while, on the other hand, the muscles of organic life, over which the
sympathetic system is dominant, when similarly affected manifest successive contractions, moving like waves.*

It need scarcely be observed that, although the abnormal condition now described as Spasm is evidenced by a disorder of muscular fibres or muscles, the cause of this disturbance is always resident in the nervous system. There is a very important and interesting variety in the connexion which subsists between the nervous stimulus and the phenomenon of muscular contraction. The former may be central, that is, operating directly on the great nervous centres, the brain, or spinal cord; or, and in the case of Local Spasm this is far the more frequent, the irritation is peripheral, and consequently the induced action is reflex.

Our knowledge of the causes of Local Spasms is as yet far from being perfect, and in not a few instances the attempt to determine these, notwithstanding the most careful inquiry, signal fails. The aetiology of general convulsive disorders is indeed more advanced, and may serve to elucidate doubtful points in relation to the more limited and less serious affection.

The late Dr. Graves of Dublin was one of the earliest to direct attention to the frequency with which various nervous affections, of which Spasm is one, and not the least interesting, are dependent on reflected nervous irritation. He has graphically described the sudden and complete relief afforded to a young lady who had suffered most severely from spasmodic cough after the discharge of a tape-worm, which had been effected by a large dose of oil of turpentine with castor oil.† The subject thus adverted to by Graves has more recently attracted the attention of several competent observers, more especially of M. Davaine in France,‡ and Dr. Heslop§ of Birmingham. Their statements show that the presence of worms in the intestinal canal is a frequent cause of remote nervous phenomena, including Spasms, and throw doubt on the assertion of Romberg, that the influence of worms in producing convulsions has been formerly over-estimated. Again, a careful study of the whole phenomena in that most interesting disease, spasmodic asthma, has led to the conclusion that the spasmodic affection in it, seated in the smaller bronchial tubes, may be induced by an irritation of the nervous system, which is either centric or eccentric.

† Clinical Lectures, Lecture xl., Bronchitic Asthma, Cough.
‡ Trait des Entozoaires. Paris, 1860. M. Davaine remarks:—"Tous les organes, pour ainsi dire, peuvent ressentir l'influence sympathique des vers du canal intestinal : la fausse perception des odeurs, la dilatation de la pupille, l'amaurose permanente ou passagère, l'exaltation de l'ouïe, la perversion du goût, le prurit et les fourmillements à la peau témoignent de l'action sympathique des vers sur les sens; d'autre côté, la somnolence ou les vertiges, les rêves flâcheux, les spasmes, les douleurs vagues, la toux, la dyspnée, les palpitations, les intermittences du pouls, la faim insatiable ou l'anorexie, la saivation, la qualité des urines, l'amaigrissement, témoignent également de leur action sur le système nerveux, sur les organes de la respiration, de la circulation, de la digestion, sur les sécrétions, enfin sur la nutrition."—Page 48.
In the former case the irritation is in the nervous centres themselves, the brain, or spinal cord. In the latter, and it is by far the more common in its occurrence, the irritation is applied at a distance from the nervous centres. This subject has been very fully and ably illustrated by Dr. Hyde Salter, in whose work examples the most interesting and conclusive as to the essentially nervous origin of asthma are to be found.*

In treating of what may be styled central asthma, Dr. Salter gives, among others, the following case:—A man about fifty was subject to epilepsy. His fits had certain well-known premonitory symptoms, and occurred with tolerable regularity—not once a fortnight. On one occasion his medical attendant was sent for in haste, and found him suffering from violent asthma. The account given by his friends was, that at the usual time at which he expected the fit he had experienced the accustomed premonitory symptoms, but instead of their being followed as usual by the convulsions, this violent dyspnea had come on. Within a few hours the dyspnea went off, and left him as well as usual. At the expiration of the accustomed interval after this attack, the usual premonitory symptoms and the usual epileptic fit occurred. On several occasions this was repeated, the epileptic seizure being as it were supplanted by the asthmatic. Nothing seemed to be amiss with the lungs either before or after the attack. Dr. Salter truly observes, that such a case as this appears to admit of only one interpretation, that the particular state of the nervous centres that ordinarily threw the patient at certain times into the epileptic condition, on certain other occasions, from some unknown cause, gave rise to bronchial Spasm; that the essential diseased condition was one and the same, but that its manifestation was altered, temporary exaltation and perversion of the innervation of the lungs in the asthmatic paroxysm supplanting unconsciousness and clonic convulsion in the epileptic seizure. It has occurred to the writer to witness in one instance an alternation of phenomena bearing a close resemblance to that observed by Dr. Salter. The patient, a young man, was admitted to the Royal Infirmary of Edinburgh, on the recommendation of Dr. Turner of Keith. He had for several months previously been subject to cerebral attacks, attended by loss of consciousness, and occasionally by convulsive movements of the muscles of the face and extremities. These continued to occur during the patient's residence in the hospital, observing for a time the same periodicity which had antecedent to that time always distinguished them, when, on three separate occasions, and in the most distinct manner, an attack of asthma took the place of the more manifest cerebral disorder. The loss of consciousness and convulsive movements again occurred in a modified form: and after the lapse of several weeks, during which various remedies were employed, the patient left the Infirmary to return home, his condition having materially improved. Besides instances of the nature just alluded to, there are

other examples of asthma, which, although in by no means so distinct a manner, must be held as caused by some impression taking origin in the nervous centres, and responding in a mysterious manner with certain feelings or emotions of the mind; such are the cases in which fear, excitement, and fatigue operate.

Now, passing to a very brief consideration of bronchial Spasm, dependent not on centric but peripheral irritation. Dr. Salter speaks of three degrees of remoteness of the application of the stimulus producing asthma, and consequently of three groups into which the reflex cases of the disease may be divided:—1st. Those in which the source of irritation is alimentary, and chiefly gastric. 2d. In which the irritation is more remote, but still confined to the organic system of nerves, as, for example, asthma produced by a loaded rectum, by the presence of tape-worm, or ascarides. 3d. Cases in which the cerebro-spinal system is the recipient of whatever irritation is the cause provocative of the attack, as, for example, was illustrated in a most remarkable instance recorded by Dr. Chowne, where the application of cold to the instep produced in the most direct manner the asthmatic paroxysm. Looking to the first, and by a long way the largest, of these three classes of cases, the nerve irritated is the gastric portion of the pneumo-gastric; through it the stimulus reaches the medulla oblongata, and from that portion of the nervous centre it is again transmitted to the bronchæ by the pulmonary filaments of the same nerve. It is indeed of the highest importance in a therapeutic point of view to notice this chain of connexion. We are thus called to recognise in the paroxysm of asthma a disease not unfrequently originating in disorder of the stomach; and it may be assumed as a correct conclusion, that a large proportion of the sufferers from this severe spasmodic affection are to be relieved by attention being given to their diet and regimen. But even here we should be adopting too limited a notion of the influence of the digestive and assimilating processes in the production of asthma did we conclude that those cases alone are examples of this nature, in which bronchial spasm is induced by reflex stimulation directly through the important nervous trunk—the pneumo-gastric. There are over and above, numerous instances in which this direct communication of the influence exerted will not apply. In such the occurrence of the Local Spasm does not so speedily follow the introduction of food into the stomach as in many of the former cases, and therefore we must look for a somewhat different explanation. We find it in the disordered condition of the blood; the faulty assimilation is no doubt the primary cause of this, but the unhealthy blood is in such instances the direct irritant; by its operation on the nervous distribution through the lungs the bronchial Spasm is caused. This humoral origin of asthma affords in all probability the most satisfactory explanation of the frequent occurrence of the nervous disorder in persons who are gouty. The accuracy of the view thus expressed is further evidenced by the circumstance that such sufferers are benefited by a plan of treatment
which tends to eliminate the essential poison of gout from the system; often, indeed, are benefited by such a plan of treatment only. In these cases remedies need scarcely be directed to the chest: it may be possible to relieve, it is impossible to subdue, by antispasmodics a bronchial spasm so induced; but on the other hand, by acting freely on the great emunctories of the body, on the skin and kidneys, the disease is to be met and overcome.*

Allusion has been made to the production of bronchial Spasm as determined by reflex irritation, and also by an impure condition of the blood. The same precisely holds true of cardiac Spasm. The irregular, un rhythmic, and painful contractions of the heart known under the name of palpitation, are found in close connexion with various derangements of the general health and of special organs. Among the latter, those of the alimentary canal, but particularly of the stomach and the uterus, occupy the chief place. Perhaps the most painful of all the forms of cardiac palpitation is that resulting from either an imperfect depuration of the blood, or from a regular blood impoverishment, or anemia, as is so frequently observed in cases of amenorrhea and chlorosis.

We pass to a brief consideration of Spasm as occurring in the muscular organs which constitute the alimentary canal. It affects the stomach and intestines as well as the esophagus and pharynx, while the severe pain determined by its occurrence in any part of the alimentary tract is very generally accompanied by other and various symptoms which cannot with any propriety be referred to now. Painful peristaltic spasm of the intestines is usually known under the name of colic. During its occurrence, and as affording proof of its occasional violence, intussusception and prolapsus of the rectum may take place. Foremost among the determining causes of colic is to be placed the presence of indigestible articles of food and morbidly altered secretions in the intestinal canal. But, besides this, the influence of the emotions, and more especially of fear and fright, is well known; while just as bronchial Spasm may be due to reflex nervous irritation, so may intestinal-spasmodic stricture, as it is called, to distinguish a temporary and functional from an enduring and organic contraction, similarly produced, have its seat in any part of the alimentary canal. In some instances the direct exciting cause

* Laennec, who, while strongly insisting on the connexion between asthma (asthme spasmodique) et catarrh, admitted the existence of a purely nervous asthma (sans aucune complication de catarrhe), has acknowledged the great difficulty there is in the satisfactory treatment of the disease. “Beaucoup de moyens,” he remarks, “peuvent être opposés aux troubles de l’influence nerveuse qui constituent principalement l’asthme: mais ici, comme dans toutes les affections nerveuses, rien n’est si variable que l’action des médicaments; les remèdes qui réussissent le mieux chez un grand nombre de sujets sont sens efficacité pour beaucoup d’autres; et chez le même individu tel moyen qui avait produit d’abord des effets héroïques, et d’une promptitude surprenante, devient tout à fait inefficace au bout d’un petit nombre de jours. Il faut successivement en essayer plusieurs, et souvent de très-disparates: nous allons, en conséquence, parcourir les diverses séries de moyens dont on a tiré le plus d’avantage dans l’asthme.”—Traité de l’Auscultation Médiate, Affections Nerveuses du Poumon.
is seated at a great distance from the induced disorder: of this nature no more common or manifest example can be given than that of colic, often very severe, resulting from the exposure of the lower extremities, it may be of the feet only, to cold and damp. *Spasm of the pharynx and oesophagus* is one of the most interesting of all the varieties of Local Spasms. It is of common occurrence, particularly in females, in whom it shows itself either as a reflex phenomenon dependent on uterine irritation, or—and this still more frequently—as one of the most striking features in a paroxysm of hysteria. It is not always an easy task to distinguish between Spasm of the oesophagus due to organic disease and that which is simply the result of a nervous irritation. The cautious introduction of the probang or oesophageal bougie is the most ready and certain means for establishing the diagnosis.

- An irritation of the pharynx or oesophagus, of the stomach, bowels, or liver, is sometimes the direct cause of hiccups or singultus, a spasmodic affection extremely interesting in its nature. Sudden powerful jerking inspirations, accompanied by a peculiar noise, and succeeded by a brief expiration, interrupting speech, distinguish hiccup. It is essentially a reflex phenomenon; in the vast majority of instances depending on some peripheral irritation, but occasionally, as its presence in apoplexy, meningitis, and hydrocephalus testifies, determined by a central cause. There seems to be some difficulty in accounting for the occurrence of hiccup from an irritation of the phrenic nerve, as has been suggested by various writers; nevertheless it is consistent with the writer's observation in several instances of long-continued and distressing hiccup, that firm pressure exerted for a brief period over the lower part of the neck, corresponding to the situation of the scaleni muscles, so as probably to compress the phrenic, has led to its temporary and even entire arrestment. In singultus and in yawning, which resembles it in being of the nature of inspiratory convulsion,—also in *sternutatio* or sneezing, where the expiratory function is involved,—what is of consequence to notice is, as Romberg has pointed out, that the spasmodic action does not affect a single muscle, but, on the contrary, groups of muscles; and that these Local Spasms, more particularly the former hiccup, while occurring as independent affections, are still more prone to assume the symptomatic character; affording evidence of the existence of some other malady, or distant irritation.*

*Spasm of the urinary bladder and of the urethra*—what is commonly styled spasmodic stricture—are familiar to the surgeon. Vesical Spasm is not unfrequently a truly reflex phenomenon: this is witnessed on the introduction of the catheter or bougie, when violent and most painful efforts are made to evacuate the organ, even when at the time empty. Romberg insists on the action of the vesical muscles being

* "Häufiger als auf einzelne Nervenbahnen beschränkt, kommen die krampfhaften Athembewegungen zu Gruppen assoziiert vor, entweder selbständig, oder was öfter der Fall ist, abhängig, und in Begleitung von andern Affektionen." (Loc. cit. p. 354.)
due to an irritation of the neck of the bladder, that particular part being, as Sir Charles Bell demonstrated, the most vascular and the most sensitive portion of the viscus. It is when the catheter reaches, or the calculus touches, the neck of the bladder, that the ischuria is produced; and the intense pain is seen to subside whenever the irritating body is removed from that particular portion of the organ. The irritation upon which vesical Spasm depends may, as we have seen to hold true of other forms of Local Spasm, be distant from the induced phenomenon. It may be resident in the kidneys, or in any part of the intestinal canal, but very specially in the rectum. Hemorrhoids are a frequent cause of vesical Spasm; and it is well known in how distressingly severe a degree that is apt to occur after the operation of their dilatation. Exposure of the surface of the body, especially of the feet, to cold and wet, and depressing mental emotions, act in the same way.

As our object in this Article has been, not to illustrate every example of Local Spasm, but rather to indicate the nature of this special morbid action by a brief consideration of some of its more important and most frequently occurring varieties, we shall now take a very rapid survey of a few other forms, and bring our remarks to a conclusion by offering some general observations with a special reference to treatment. There is a peculiar variety of Local Spasm affecting certain muscles of the face, and giving while it lasts a very strange aspect to the individual. In the *histrionic Spasm of the face,* by which title this affection is known, there are, in the language of Ronberg, "grimaces, alternating or lasting, on one side, seldom on both sides, of the face."* Pain is occasionally, but by no means necessarily, an accompaniment of the disordered muscular action. A local malady essentially, because affecting the muscles governed by one nerve, the seat of the Spasm is in some instances still further localized by there only being one of the branches of the seventh pair involved. Of the latter are *blepharospasmus,* or Spasm of the eyelids, and the *rimus caninus.* The peculiar convulsive grin thus named is caused when the molar and labial branches are affected. To it the terms *spasmus cynicus* and *sardonic laugh* are likewise applied. The relation of facial Spasm to chorea must not be overlooked; this association has been frequently noticed: and it is also a matter of not unfrequent observation that the Local Spasm lasts in some cases for a considerable period after the disappearance of the general nervous disorder with which it had been in the first instance connected.

*Masticatory Spasm* is witnessed in its most formidable degree when, as trismus, it accompanies, or is itself the chief element in, tetanic convulsions. In a much milder degree Spasm in the muscles which are supplied by the motor division of the fifth pair is seen as a reflex action, determined, as in children, by the presence of worms in the intestinal canal, or by the progress of dentition. The Spasm of the muscles is sometimes associated with a grinding of the teeth. To the

*Loc. cit. "Mimischer Gesichtskrampf."*
occurrence of the latter symptom in persons of the gouty diathesis attention was called by the late Dr. Graves. Such grinding of the teeth continued for years as a daily habit, and produced very remarkable changes in the conformation of these organs, affecting sometimes one side of the jaw, sometimes both; so that in confirmed cases the teeth were frequently found ground down to the level of the gums.*

Spasm of the muscles of the eye, dependent on an irritation of the third, fourth, or sixth nerves, is seen in strabismus,—which is to be distinguished from the paralytic form by the movement of the eyeball in other directions being in the former case possible,—and in nystagmus. These spasmodic affections equally with others acknowledge a peripheral or central origin. Both are of common occurrence in connexion with intestinal and dental disorders, but they are also not unfrequently the indications, sometimes among the very earliest, of mischief, inflammatory or otherwise, commencing at the base of the brain.

Painful Spasms of the muscles of the extremities are of very frequent occurrence; and with this affection, more especially seated in the lower limbs, and there in the calves, we are especially familiar under the name of cramp. The attack of cramp is usually sudden; and it frequently occurs at night, the person in bed being awakened from sleep by the seizure. During its continuance the muscular fibres are gathered up into a hard knot, which is always easily felt by touch, and may often be seen. The pain is very severe, and produces a feeling of sickness and depression, which may even lead to syncope. The patient not unfrequently gives utterance to an irrepressible exclamation or scream. Cramp usually lasts only for a few moments; it may, however, continue for minutes, and even hours. A sudden cessation of the Spasm may occur, or a more gradual relaxation of the muscular fibres ensue; but in either case, if the attack have been at all severe, sufficient injury during its continuance has resulted to the sensory nervous filaments as to cause a feeling of soreness, always increased by touch, and frequently an inability fully to exert the affected limb or other part for some time. The irritation of the sciatic nerve, upon which the painful Spasm of the muscles of the calf depends, is intimately connected with disorder of the stomach and bowels, and is also particularly prone to occur in persons of the gouty and rheumatic habits.

In Asiatic cholera the occurrence of intensely painful cramps contributes, as is well known, largely to the sufferings of its victims. Again, in persons of intemperate habits there is sometimes observed a tendency to the development of severe spasmodic action in the muscles, of the extremities more especially, but likewise of other parts of the body. In one instance which fell under the writer's observation a patient, having recently recovered from an attack of delirium tremens, was seized with most violent and painful Spasm of the muscles of both upper and lower extremities, during which the

---

LOCAL SPASMS.

773

fingers were powerfully flexed and bent inwards on the palms of the hands, as in the carpal contractions of children. So severe was this case, that a syncopal depression, very threatening in its character, occurred. After lasting for several hours, and exhibiting for many days a marked tendency to recur, the affection passed off, and the patient entirely recovered both health and strength.

In the treatment of local, as of general, Spasms, the great object is to remove the cause on which they depend. In the brief consideration of the different varieties of Local Spasm now offered it has been shown that in a large proportion of cases the excited muscular action is induced by reflex action; that the direct exciting cause is a distant nervous irritation. Fortunately the removal, or at all events the lessening, of this irritation is in many instances within the power of our art. Again, in those cases, of the frequent occurrence of which proof has been afforded, which are characterised by a morbid state of the blood, e.g. gouty or rheumatic, we may often be successful in our treatment by paying due attention to the therapeutical indications,—in other words, by the employment of an alterative or eliminating plan, suggested by the peculiarity of each individual case. We may as effectually subdue the morbid action of Spasm as we are constantly enabled, by the use of suitable remedies, to relieve that of pain in neuralgia. In addition we possess in various agents a power of controlling or completely removing such excited nervous action as induces Local Spasm: not indeed one upon which we can invariably rely, because we are often disappointed in the results; nevertheless the remarkable therapeutical effects which succeed the exhibition of various of the antispasmodic and calamative remedies is such as to convince us of their efficiency. Our knowledge, moreover, regarding the action of such remedies is on the increase. It is only quite recently that a valuable addition has been made in the bromide of potassium, the operation of which in removing the painful cramps of cholera, not less than in many instances averting the convulsive seizure of epilepsy, has been witnessed by numerous observers.*

Pressure firmly exerted on the thigh relieves a violent cramp of the calf, while, according to Dr. Wise, the application of a tourniquet so as to compress the blood vessels will banish the exhausting muscular contractions in cholera.

Finally, in the treatment of such exalted nervous action as determines Local Spasm, as in the proper management of every form of derangement of the nervous system, however slight or severe, let the potent influence of peculiarity in psychical constitution, and of the ready susceptibility in some to the operation of all manner of external impressions, not be lost sight of.

TORTICOLLIS.

By J. Russell Reynolds, M.D., F.R.C.P.

Definition.—A spasmodic condition of the muscles of the neck—generally clonic, but rarely tonic—whereby the head is displaced to one side, or towards one shoulder; occurring almost exclusively in adult life, and characterised by great obstinacy and chronicity.

Synonyms.—Wry-neck; spasmodic wry-neck; spasm in the muscular distribution of nervus accessorius Willisii, and of the superior cervical nerve (Romberg).*

Causes.—So far as I have seen, the male sex has been slightly more frequently affected than the female; but the difference is so small, that its existence is of no diagnostic value. With only one exception, all the cases that I have seen have presented symptoms after thirty years of age; and the majority after forty. There has been no one thing, nor any combination of circumstances, which has occurred with such frequency as to warrant a belief in its operation as an exciting cause. Once a strained position, maintained for a long time; occasionally exposure to cold; sometimes a sudden shock, either mental, moral, or physical; and at other times the presence of long-continued anxiety, or the recurrence of pregnancy, has been referred to by the patient as the cause of symptoms; but, in regard of such modes of causation, we can see distinctly that which might lead to disturbance of the nervous system of any kind whatsoever, but we fail to see anything which should conduce to this special form of derangement.

In one case that I have seen the symptoms were preceded by hemiplegia; in another by paralysis agitans of the side from which the head was turned; in a third, and fourth, and fifth, there was previous "writer's cramp;" in a sixth there was histrionic spasm of the face; but in the majority of cases the nervous system had exhibited no prior derangement, and had continued free from ulterior disturbance for a long period of years.

The position in life and the occupation of those who have suffered from Torticollis have varied widely, and I have not been able to attribute the malady with anything like constancy to that common cause of nervous disease,—overwork.

S Y M P T O M S.—There is great similarity in the symptoms presented by different individuals, when once the disease is established, and is free from accidental complications. Sometimes the commencement is sudden, but much more commonly it is gradual, and often so insidious at first that the real nature of the malady is overlooked. The patient feels uneasy in the neck, thinks that something is wrong with his cravat, or with his pillow, and only after several months discovers for himself, or is told by others, that his head is not straight. There is with this want of symmetry some uneasiness in the neck, extending from the occipital protuberance downward to one of the shoulders, and sometimes onwards into the arm, or even forearm. As the malady advances the uneasiness becomes greater, and sometimes amounts to definite pain, felt usually in the same direction. The pain is increased by voluntary efforts to bring the head into the middle line, but sometimes attains its maximum when the head is carried round to the furthest point possible by the spasmodic movement. The pain is not severe, but generally of dull, aching character; and often is relieved by lying down, and keeping the head still by resting it upon a pillow.

Observed casually, a case of medium severity would give the impression to a bystander that the patient’s cravat was uncomfortable, and that he was trying to make it less so by moving the head, in a somewhat restless manner, towards one side; or that he was making some attempt to look at an object on one side of him, which object he could not “get his head round” sufficiently far to see conveniently.

Upon more careful examination it is seen that the head is constantly being moved, by a succession of jerks, in such manner that the occiput is depressed, and the chin raised, and that the movement is in a definite direction, hour after hour, and month after month. Early in the case the individual is able so far to antagonize the spasm, by a simple voluntary effort, as to bring the head into the middle line, or even beyond it; but as time passes on this often becomes impossible, and the hands are used to pull the head back again into its proper position.

When Torticollis has existed for a few months only, the head presents a constant series of movements,—the spasm and the voluntary effort so balancing one another that the effect is that described above. But when it has lasted for a longer period, the head is habitually “carried on one side;” for the voluntary interference with the spasm, although frequent,—if not constant,—does not suffice to bring the head into a central position, being overcome by the spasmodic contraction. Sometimes, even under these circumstances, a very strong voluntary effort may restore momentary equilibrium; but the effort is attended by distress, if not by pain, and is often followed by an exaggeration of the spasm.

The muscles of the neck on the side from which the chin is turned are found hard, contracted, and often hypertrophied; those on the opposite side are frequently soft, and sometimes wasted. Early in the history of Torticollis it would seem—so far as my experience extends.
—that the deeply-seated muscles at the back of the neck are the most affected; the sterno-mastoid, at such time, being often free from spasm.— At a later period the sterno-mastoid is found hard, frequently hypertrophous.

Occasionally the muscles of the shoulder are so involved that the acromion is raised; more rarely the muscles of the face present histronic spasm; and not unfrequently there is some difficulty in controlling the movements of the arm. I have noticed sometimes difficulty of deglutition, and in a very few cases some morbid condition of motility in the leg: but these symptoms must be regarded as complications rather than conditions of the disease now under consideration; for it more frequently happens that the muscles of the neck are alone involved in the morbid contraction.

As a rule, to which the exceptions are very rare, the spasms cease during sleep; and not only so, but when the patient lies down and supports the head. They are increased by all that lowers or disturbs the general health, and by emotional excitement.

The electric irritability of the contracting muscles I have found much increased when tested by faradisation: the electric sensibility is sometimes so greatly augmented that an interrupted current, not in the least degree painful on the healthy side, was perfectly intolerable when passed through the seat of spasm. It has appeared often that the relaxed muscles, on the side opposite to the contraction, have exhibited less than their normal contractility; but I have never found them so defective that it was impossible to restore the head to equilibrium by their distant faradisation. This battery current, when continuous, and passed through the contracting muscles, relaxes the spasm and allows of temporary equilibrium; but, when interrupted, its action is similar in kind to that exerted by the induced current of faradisation: there is, however, less intensity of contraction, and much less display of elastic sensibility. The effects of either the battery current or of faradisation appear to be singularly transient, in whatever manner they may have been produced. It has often happened to me to see that a head which had been maintained in equilibrio for many minutes, and that day after day for a considerable number of days, returned at once to its spasmodic jerking the moment that the application was suspended. Sometimes it has been obvious that the spasm was subsequently increased by the electricity.

The side to which the twisting occurs has been sometimes the right, sometimes the left. There appears to be no special proclivity to the affection of one side rather than the other in either sex; but when once the malady has shown itself, its pertinacity is remarkable: it remains in exactly the same position, with slight tendency to extend; or it may in rare instances disappear for eight or nine years, and then return to the member that it had previously affected. In many cases progress is so slow that no change is observable after several years—i.e. no change as to locality—whereas in others the malady seems to extend either upwards or downwards, and involve muscles not
TORTICOLLIS.

implicated at the first. In this manner the face may be distorted, or the arm may be rendered partially useless by either rigidity or weakness; the head becomes more or less fixed in an oblique position, the ear of one side being drawn down to the shoulder, and the chin thrown upwards and outwards in the opposite direction. When left entirely to itself,—i.e. when not interfered with by either the will, the ideas, or emotions of the patients, or by any influence from without,—the spasm is tonic, and the head may remain for hours drawn to one side, but motionless. This is rarely, if ever, noticed early in the history of a cure, and sometimes it is never observed; but, even when it occurs after several years' duration of the spasm, the slightest emotional disturbance or attempt at voluntary movement brings back the clonic contraction: and the only difference to be recognised between the early and the later stages of the malady is, that in the latter the head is never brought back to the position of exact equilibrium, and that there is less obvious movement of the head; for, as it seems, the habitual struggle between volition and clonic spasm is given up, and the latter, having gained the day, allows tonic spasm to take its place.

The mental faculties, the sensibility of the skin, the special senses, and the general health undergo no necessary changes in Torticollis. In some highly-marked instances there has been complete integrity of function in every direction; the one thing that has been wrong has been the disease itself. Sometimes the general health has been impaired, the patient has been anemic and weak; but this has been frequently the result of the annoyance occasioned by the spasm, and very rarely the supposed cause of its development.

Numbness and anesthesia may occur in the arm, together with edema, when the scaleni are so much affected as to press upon the brachial plexus and its adjacent veins.*

Diagnosis.—The symptoms that have been now described are sufficient when carefully regarded to enable the practitioner to distinguish this disease from every other. An accidental exposure to cold may produce "stiff-neck," but here the head is permanently fixed in one position, and maintained therein, not by spasmodic rigidity of muscle, but by the fear of pain which, as the patient knows, any movement may occasion. Such malady has its relations to pleurodynia, lumbago, and "muscular rheumatism;" it is sudden in its development, and temporary in its duration, and could only be accidentally mistaken for Torticollis. The opposite error is sometimes made,—viz. that of regarding genuine spasmodic Torticollis as a simple "stiff-neck from rheumatism or cold." In its earliest stage, however, genuine Torticollis should be at once distinguished by the clonic character of the spasm, and freedom from pain on movement.

Injuries to the spine occasionally produce stiffness of the neck, and this to such a degree that the head may be permanently placed in some awkward position. In such cases the spasm is tonic; there is

marked tenderness of the spinous processes, and with this some fulness or hardness around or behind the vertebral column; and there is also some impairment of the motor or sensory properties in the arms and legs.

In certain organic diseases of the brain accompanied by hemiplegia there is sometimes Torticollis, just as there is synergic movement of the eyeballs; but the mode of onset of symptoms is such that a case of cerebral apoplexy cannot well be confounded with the malady now under consideration. The opposite mistake has, however, sometimes been made, and an individual who is beginning to suffer from Torticollis spasmodica has been supposed to be the subject of organic disease of the brain. For the distinction between these two very different conditions it is sufficient to bear in mind that in the one the disease is limited to the neck, in the other it occurs in combination with marked hemiplegia; that in the former the spasm is clonic, in the latter tonic; and that in the first the development of symptoms is insidious, gradual, and local, whereas in the second it is sudden, and of wide distribution.

It is enough to mention the existence of cases in which growths, benignant or malignant, may affect the position of the head, in order to prevent the occurrence of any errors in diagnosis.

Pathology.—Anatomical inquiry has not yet shown the locality or existence of any special lesion of the nervous centres with which Torticollis is necessarily associated. Physiological experiment has proved that it may exist when the spinal accessory nerve is irritated at its passage through the foramen lacerum,* or when injury is inflicted on certain muscles, upon the olivary body, or the auditory nerve.† The disease would appear to be one of those curious conditions—not yet fully understood—in which some "centre" of associated movements is so altered that there follows a disturbance of the normal equilibrium; a disturbance exhibiting itself at first by dynamic change, but subsequently leading to structural alterations in the affected muscles. It has its analogies in writer's cramp and histrionic spasm, and its peculiar and intimate pathology is a question as yet reserved for further investigation.

Prognosis.—When once established,—i.e. when fully developed and of three or four months' duration,—Torticollis is one of the most obstinate of maladies. It has sometimes yielded to treatment, under favourable circumstances; but it has almost invariably recurred, and has proved capable of resisting all efforts made for its relief.

Unfortunate as the prognosis is with regard to the cure of this special malady, there is one ground for consolation,—viz. that it is not by any means necessary, nor is it at all highly probable, that the victim of Torticollis should suffer from any other nervous disease.

* Volkman, quoted by Romberg, loc. cit. p. 316.
† Brown-Séquard, Lectures, p. 194.
TORTICOLLIS.

Sometimes it forms but part of a general nervous disorder; but, as a rule, it exists alone; and although it may continue for many years, the source of great but measurable annoyance, it does so without entailing any danger to life, or any high probability of ulterior change. Prognosis, therefore, is based upon the duration of the disease, and its complication with other signs of nervous malady. When it exists alone, the patient may look forward to a troublesome and obstinate affection; but he may, at the same time, know its limits, and be directed to go on without fear of further mischief:

Treatment.—In its early stages Torticollis has yielded to various plans of treatment; iron, setons, moxæ, rest, mercurials, electricity, and the division of nerves or of muscles, have each been followed by a cure: but in the advanced stages no one, nor any combination, of these modes of treatment has availed to cure, or even to modify, the disease.

I have used all kinds of soothing applications, have employed electricity in every form, and have failed to influence the disease when once it has become firmly fixed; but have found that the continuous current has been useful when the malady has existed for a few months only, and have also at that period seen notable advantage from the continued application of morphia by the method of hypodermic injection.

It would seem desirable to enjoin rest; to secure the regulation of the general health; to apply a moderate continuous current to the muscles which exhibit spasm, and a mild induced current to their antagonists; and to inject morphia, hypodermically, for a lengthened period. It is not essential that the morphia should be injected into the neck; it may be introduced into the arm or thigh, or any other convenient locality: but it is important that its use be steadily continued, and that the quantity injected be gradually increased until a definite effect is produced upon the spasm. Beginning with the tenth part of a grain, the quantity may be increased, if necessary, until two, or even three, grains are injected twice daily; and when the patient can bear this amount, the spasm has sometimes yielded. But it often happens that morphia, even by hypodermic administration, cannot be borne, from the fact of its producing nausea, constipation, and an amount of malaise that is greater than the evil it is intended to relieve; and in such cases the Torticollis is positively increased by the injection. Several patients whom I have known with Torticollis have positively refused to continue the injection of morphia from the misery which it has thus occasioned.

Mechanical contrivances have been employed in order to force the head into position; but these, although so managed as to be borne for a short time,—e.g. to enable a clergyman to get through a service, or a doctor to visit two or three patients in succession,—are often found to be productive of so much annoyance, or even pain, that the patient would rather trust to his own hands or to the "chapter of accidents"
in order to get through his work. The most simple, and at the same
time most effective, appliance that I have seen for mild cases is that
devised by Dr. Hearne of Southampton; but it has failed to be of
service when the disease has been of long duration. Mr. Heaths
Bigg has constructed several machines which meet the difficulty for
short periods of time; but I have not yet seen any apparatus which
a patient with confirmed Torticollis could bear habitually.

Division of the nerves has been useless,* and division of the sterno-
mastoid worse than useless, for it has led to an exaggeration of the
spasm in the deeper-seated muscles at the back of the neck, as I had
occasion to observe in a well-marked case that came under my notice
some years ago.

* Romberg, loc. cit. p. 319.
LOCAL ANÆSTHESIAE.

BY J. WARBURTON BEGBIE, M.D., F.R.C.P.E.

The term Anaesthesia (a privative, αἰσθησία, sensibility), indicates deprivation or loss of sensibility, and was first employed by the distinguished Cappadocian physician, Aretæus.* There exist three abnormal modifications of the function of sensation: first, it may be lost; second, it may be exalted (hyperæsthesia); third, it may be perverted.

By Local Anaesthesia we understand a morbid state of sensibility, in which the normal physiological sensation of a part is abolished entirely, or nearly so.

Since the introduction of ether and chloroform inhalation, for the purpose of destroying pain, it has been customary to describe these valuable agents as anaesthetics, and the condition of insensibility into which the person is thrown by their action as Anaesthesia. With this interesting phenomenon we have at present no concern.

In Local Anaesthesia the want or failure of the due impression must arise from a morbid state of the extremities of nerves, or of an afferent nerve ceasing to convey the impression to the sensorium, or of the sensorium itself.

Thus we are entitled to limit the seat of the morbid influence, because these three organs, or classes of organs, are concerned in the production of each sensation.

With precisely the same signification as Anaesthesia, the expression, paralysis of sensation, or of the nerves of sensation, has been employed. It were better, however, to abandon the use of paralysis in this sense altogether, and to restrict it to the loss of power of motion. The intimate connexion of paralysis and Anaesthesia is abundantly conspicuous: the latter is very frequently noticed as an antecedent phenomenon of the former, or they occur simultaneously; and while paralysis lasts Anaesthesia may continue, or sensation may be restored long before the recovery of the power of motion.

The special situations in which Anaesthesia is met with, or may be considered apt to occur, are various. For convenience of illustration the following classification may be made, and to the forms now to be mentioned attention will be very briefly directed:—(a) Anaesthesia

* ἢν δὲ ἀφῇ ἔκλειτη μονὴ κοτέ,—σπάνως δὲ τὸ τούθε,—ἀνασθησία μᾶλλον ἡ πάρεσι κικλῆσθαι.—Περὶ Παραλόσεως. Περὶ Αἰτίων καὶ Σημείων Χρονίων Πάθων. Βιβλίων Πρώτων.
of the skin (cutaneous Anæsthesia). (b) Anæsthesia of muscular nerves. (c) Anæsthesia of sensorial nerves. (d) Anæsthesia of the fifth pair of nerves. (e) Anæsthesia of mucous surfaces. (f) Anæsthesia of the viscera.

(a) Anæsthesia of the Cutaneous Nerves.—The notable and lasting diminution, or the entire loss, of the tactile sense of the skin is what is understood by cutaneous Anæsthesia. It is by a careful examination as to the delicacy of tactile sensibility, and the perception of degrees of temperature, that we are enabled to determine the extent to which Anæsthesia of the surface exists. For the former purpose the mere statements of the patient will not suffice. Besides measuring the degree and determining the precise seat of Anæsthesia by the point of the needle, recourse must be had to the method of experiment suggested by Weber, testing the consciousness of the patient, while blindfolded, to the two points of a pair of compasses placed at different parts upon the skin, or, which is still more satisfactory, employing the delicate little instrument known as the æsthesiometer of Dr. Sievæking. The ready and accurate determination by the patient of degrees of temperature, heat and cold, is impaired or destroyed: it is not uncommon to find hot things styled cold, and cold things hot. In marked instances of cutaneous Anæsthesia the power of resisting the injurious influence of temperature is lost; and not only so, but, owing to a similar defect, superficial sores are readily formed on parts of the body exposed to even a slight degree of pressure. Evidence of the derangement of the circulation is afforded by a change in the colour of the affected part; it is apt to become livid or blue in appearance, and extravasations of serum, and even of hæmatin, occur. Distressing sensations are experienced by the patients,—chiefly numbness and pricking; also formication.

In alluding to the treatment of cutaneous Anæsthesia, the distinguished German writer on nervous diseases truly observes, "Die Behandlung der Anæsthesia cutanea war bisher eine oberflächliche, im wahren Sinne des Wortes;" but while this is to be regretted, we may reasonably anticipate an increase of our knowledge, owing to the much more satisfactory manner in which the causes and seat of disease have of late, and are at the present time, being investigated.

(b) Anæsthesia of Muscular Nerves.—The loss of the power of motion is usually unassociated with any marked degree of muscular Anæsthesia. On the other hand, instances are on record in which a very perfect insensibility to pain has existed in muscles, while the power of moving them has been retained. It is of the utmost importance to distinguish between the loss of tactile sensation (cutaneous Anæsthesia) and the definition of sensation in muscles, for without carefulness in examination these two are capable of being, and in some instances have no doubt been, confounded. Romberg makes the interesting observation, that muscular Anæsthesia, without the loss of or any damage done to tactile power, exists in tabes dorsalis.*

* Muskelnæsthesie.
(c) Anaesthesia of Sensorial Nerves.—The nerves of special sense which thus suffer are the optic (Anaesthesia optica), the Auditory (Anaesthesia acoustica), the Olfactory (Anaesthesia olfactoria; Anosmia), and the Gustatory (Anaesthesia gustatoria; Ageustia). To the many interesting affections included under these terms—for example, amblyopia and amaurosis under optic Anaesthesia—it is quite impossible in this brief notice of Local Anaesthesiae to make any reference, while such important diseases demand a separate and detailed consideration.

(d) Anaesthesia of the Fifth Pair of Nerves (Facial or Trigeminal Anaesthesia).—Physiological experiments have demonstrated the remarkable effects produced by section of the fifth pair; of these insensibility of the face, eye, nostrils, cavity of the mouth and tongue, is the most conspicuous: while the extent of the Anaesthesia is of course determined by the nervous injury being limited to one or more branches, or, on the other hand, involving the trunk before division. Experimental inquiry, as well as clinical observation, have further shown that when injury or lesion of the nerve exists within the cranium, the resulting phenomena are not such as are included in Anaesthesia merely, but paralysis and impairment or loss of special sense are also induced. Romberg,* in directing attention to the different diagnostic symptoms, has indicated certain very important particulars, as follows:—

(a) The more the Anaesthesia is confined to single filaments of the fifth pair, the more peripheral the seat of the cause will be found to be. (b) If the loss of sensation affects a portion of the facial surface, together with the corresponding facial cavity, the disease may be assumed to involve the sensory fibres of the fifth pair before they separate to be distributed to their respective destinations; in other words, a main division must be affected before or after its passage through the cranium. (c) When the entire sensory tract of the fifth nerve has lost its sensation, and there are at the same time derangements of the nutritive functions in the affected parts, the Gasserian ganglion, or the nerve in its immediate vicinity, is the seat of the disease. (d) If the Anaesthesia of the fifth nerve is complicated with disturbed functions of adjoining cerebral nerves, it may be assumed that the cause is seated at the base of the brain. Thus facial Anaesthesia, as a phenomenon of disease, may be in itself a simple, really trivial, affection, or it may be the indication of serious organic disease. In the former case it will be apparently independent and isolated; in the latter, linked with other striking features, its significance will as little escape observation as its existence.

Facial Anaesthesia in some instances comes on gradually; in others its occurrence is sudden. Neuralgic pain, or a condition of local hyperæsthesia, may precede its development; while facial palsy and facial Anaesthesia are occasionally associated.

(e and f) Anaesthesia of Mucous Surface, and of the Viscera.—The morbid condition in such circumstances must depend on a failure of

*Anästhesie des Quintus Lehrbœch der Nervenkrankheiten.
the sympathetic to conduct the impression to the brain; but, as a general rule, impressions made on the ganglionic nervous system are not thus conveyed, and it requires a powerful irritation, or condition of notable hyperæsthesia, in order that a consciousness of their existence should be established. The inquiry into the operation of the organic nervous system is one of very great difficulty, and Romberg has truly remarked in regard to it, "Von vorn herein bekennen wir unsre unbekanntschaft mit diesen Zuständen, die bisher nicht einmal zur Sprache gekommen sind, und deren Forschung mit grossen Schwierigkeiten verbunden ist."

DISEASES OF THE STOMACH.

BY WILSON FOX, M.D. LOND. F.R.C.P.

I.—Disorders of Function.

The disturbances in its physiological functions which characterise disorders of the stomach present but few characteristic features by means of which those arising from other than organic diseases can be distinguished from those depending on anatomical alterations in its coats. The significance of the symptoms met with must therefore in the majority of cases be estimated from the concomitant circumstances by which they are attended, and their treatment must vary with the causes on which they depend. It is not, however, unimportant that these should be briefly reviewed, and in the present chapter a consideration will be given to the causes of such derangements. Their diagnosis and treatment will, however, be more appropriately considered in subsequent sections in relation to the disorders in which they originate.

A. Sensation.—Pain in the stomach has received various names,¹ the most common of which are Cardialgia, Gastrodynia, or Gastralgia. The subjective sensations embraced under these terms present all possible variations of degree, severity, and duration, from a vague sense of uneasiness to intense and almost unendurable suffering.

The seat of pain, originating in the stomach, presents some remarkable differences. Ordinarily it is epigastric or post-ternal; but it

¹ These terms have been applied with such varying meanings by different writers, that it is scarcely correct to speak of them as strictly synonymous, except as being expressions of the common element of perversely sensation. The first two are in most common use in this country, where Cardialgia is more commonly identified with Acidity or Heartburn (Copland, Dict. ii. 329; Cullen, loc. cit. ii. 465), and Gastrodynia with Pain, in the strictest sense of the word. On the other hand, in France and Germany (Georget, Dict. de Méd. art. "Gastralgia"); Romberg, Dis. Nerv. Syst. i. pp. 104, 129; Bamberger, Krauk. der Chylopoiet. Syst. 163) Cardialgia (which is the classical expression of the older writers, Hoffmann, J. Frank, Schmidtmann, and Trnka) is used for the severer forms of pain, associated with intense depression and faintness, and is sometimes further limited to those of paroxysmal and spasmodic character; while Gastrodynia is employed for pain of less severity, but more continuous in character. The term Gastralgia, very little employed in this country, is used in France to signify a much wider range of phenomena, but all embracing various forms of uneasiness observed during the digestive process. Barras (Traité sur les Gastralgies et les Enteralgies) defines it as signifying the "morbid sensibility of the stomach" of Johnson; but, under the theory of the neurotic origin of Dyspepsia, he applies it to almost all forms of indigestion not having an inflammatory or an organic cause. See also Valleix, Guide du Médecine Pract. iv. 3.
DISEASES OF THE STOMACH.

may be felt in the hypochondria or in the umbilicus. Dyspeptic disturbances are frequently associated with tenderness of the dorsal and thoracic muscles, especially about the shoulder-blades. Cancer and ulcer are also very commonly associated with severe dorsal pain, and in some cases more distant neuralgias\(^1\) are attributable to these causes.

There can be little doubt that the mucous membrane of the stomach, though ordinarily possessing but little sensibility, may have this increased under the influence of disease, though the variations in its manifestation under these circumstances are not always explicable. There appear also to be at least two distinct methods through which painful sensation can be produced in this organ; and when it can be made practically available, this distinction is of some importance as a clue to treatment. Thus in one set of cases it may be referred to the direct agency of the sensory nerves of the mucous and sub-mucous tissues; in another, cramp or spasm of the muscular coat may be the determining cause of pain of considerable intensity; while, in a third class, the co-existence of both becomes a matter of great probability.

The conditions of the stomach giving rise to pain may be summarily expressed as follows:—

1. The presence in its interior of foreign substances of an irritating character.
2. Organic diseases altering the anatomical structure of its coats.
3. Perversions of its secretions.
4. Perversions of innervation:
   a. Proper to stomach.
   b. Reflected from other organs.
   c. Originating in the nervous centres.

1. Foreign bodies usually appear to cause pain through exciting spasm of the muscular coats;\(^2\) and this explanation is probably applicable to the pain arising from indigestible food being swallowed, or from bile regurgitating from the duodenum, or from flatulent distension by gas, or from acrid substances arising from fermentation. Sharp substances, on the other hand, may directly injure the nerves of the organ;\(^3\) and the pain arising from corrosive poisons is probably in great measure due to this latter cause.

2. Inflammation, unless when of great intensity, or when caused by corrosive poisons, or accompanied by aphthous ulcerations or haemorrhagic erosions, seldom causes pain of extreme degrees of intensity. Very considerable epigastric uneasiness and distress often, however,

---

\(^{1}\) As of the fifth nerve; Andral, Clin. Méd. ii. 158.
\(^{2}\) Beaumont, loc. cit. 165, 228, 229, found that cramp-like pain was excited by passing the thermometer into the pylorus in Alexis S. Martin's stomach; but in other cases of Gastric Fistula the sensations produced by touching other portions of the stomach appear to have been rather those of sickness or faintness than of actual pain. Murchison, Med.-Chir. Trans. xii. 16.
\(^{3}\) See a case quoted from Velpeau by Dr. Budd, of a fork swallowed, loc. cit. p. 276. Also a case by Mr. Marshall, where a number of pins were found in the stomach, Med.-Chir. Trans. xxxv. Also a case by Marcet (Med.-Chir. Trans. xii.), of a man who, on several different occasions, swallowed a number of clasp-knives.
attend this process; so that this distinction is only of comparative value.

Cancer and chronic ulcer are amongst the most frequent sources of severe and continuous pain in the stomach. Their prominence in this respect depends in great measure on the invasion of large branches of nerves in the destructive processes which they occasion, or in cicatrical contractions resulting from these, and also on spasmodic action of the muscular coats, resulting from obstructions of the pylorus, and on the irritating secretions to which they may give rise. They may, however, in exceptional cases proceed to a fatal termination without any appearance of this symptom.

Diseases of the pyloric orifice are causes of pain through the spasmodic contractions which they occasion, as well as by the flatulent distension resulting from the fermentation of the food thus delayed in the stomach.

3. Perverted secretions, when acid, may give rise to pain from their irritating qualities. In some instances, however, the symptom attends the secretion of neutral fluids; and in either case it is probably questionable whether both the secretion and the disordered sensation are not common expressions of a more general cause affecting the innervation of the stomach. The fallacy of confounding acidity from hypersecretion with that arising from fermentative processes must also be guarded against; in the latter case the pain is often caused by spasmodic contraction, arising from flatulent distension.

4. Pain of a purely nervous origin, unattended by undue muscular spasm from flatulent distension, or by perverted secretion, is a comparatively rare event in the history of disorders of the stomach.

These cases will be more fully alluded to hereafter, when it will be seen that they most commonly occur in cases of hysteria and hypochondriasis, or in patients of a rheumatic or gouty diathesis, or are produced by reflex disturbance originating in other and distant parts. (See chapter on the Neuroses of the Stomach.)

It is an uncertain point whether the nerves which are affected in these cases are the branches of the vagus or of the aélic axis.1

In many cases, especially of chlorosis, the neuralgia appears to depend on the general condition of the system, disappearing with improvement in the state of the blood.2 Direct evidence of pain of this class originating in the central organs of the brain or cord is rarely afforded,3 though the absence of any demonstrative cause may at times lead to the suspicion of such a mode of causation. Many also of the painful sensations felt in the stomach are directly due to derangements in other organs. Among those which most frequently produce this effect are especially to be mentioned disorders of the uterus and ovaries, and many severe cases of gastrodinia are connected

2 Niemeyer, Lehrb. Path. Therap. i. 545.
3 See a case by Bamberger, loc. cit. 168.
DISEASES OF THE STOMACH.

with disturbance of the menstrual function. To these must be added gall stones, diseases of the duodenum, abdominal aneurism, and pericarditis.

DIAGNOSIS.—The difficulty in the distinction of pain of neuralgic or spasmodic origin from that originating in organic diseases is very considerable. It will be more fully dwelt upon hereafter under the diagnosis of those affections. It may be sufficient here to mention that neuralgic pain is most common in the earlier periods of life, and in the female sex (in whom it is usually associated with uterine disturbances, and also with other nervous phenomena), that it affects but little the function of digestion, and that it is often most felt when the stomach is empty. Pain felt after food has a gravity commonly proportioned to the time which has elapsed before it is perceived. If occurring late, it may be due to flatulence; but pain of any severity, occurring early, and continuing long after the ingestion of food, and particularly when it is relieved by emptying the stomach, is always to be regarded with suspicion of its origin in organic disease. Pain of a continuous character and of a fixed site has also graver features than that which is more migratory and intermittent.

The indications obtained by pressure are of some value in elucidating the cause of pain. That arising from ulcer, cancer, and also the uneasiness felt in inflammatory states of the stomach, is generally, but not invariably, aggravated by this proceeding. Pain of nervous origin, and that arising from flatulent spasm, is, on the other hand, usually relieved by pressure firmly exercised.

Some affections which simulate gastric pain deserve a brief notice:—

(a) Pain in the abdominal muscles has been shown by Briquet to be frequently mistaken for severe gastrodynia. He states that it is distinguished by a superficial tenderness, by its preferential seat in the left recti and obliqui abdominis, by its affecting not only the fleshy parts, but also their tendinous attachments, and by its being frequently accompanied by dorsal pain, and by tenderness on pressure in the vertebral groove (rachialgia, Briquet). He is of opinion that it may exist independently of any affection of the stomach, though it may occasionally be excited by reflex sympathy, when this organ is diseased.

1 See Neuroses of the Stomach.
4 Much in these cases depends on the seat of the disease.
5 Traité Clinique et Thérapeutique de l’Hystérique, 1859, p. 216 et seq.; termed by him "Myosalgia" and "Epigastralgia" (corresponding to the Myalgia of Dr. Inman, "Spinal Irritation").
6 This opinion is in some degree corroborated by Bernard’s observation, that prick ing the solar plexus and semi-lunar ganglion caused involuntary movements of the pectoral and abdominal muscles and of the diaphragm (Lec. Syst. Nerv. i. 363). I have met with unequivocal tenderness in the muscles of the vertebral groove and in the abdominal muscles in cases of gastric ulcer. Traube also has noticed both hyperesthesia and anesthesia of the cutaneous surface in cases of ulcer (Deutsche Clinik, 1861, p. 63).
(b) Rheumatic pains of the abdominal muscles are another source of fallacy. They are distinguished both by superficial tenderness and by pain in movement.

(c) Epigastric pain has also been observed in cases of functional or organic disease of the spinal cord. In the former class of cases, when affecting the skin, it is distinguished by the very superficial tenderness, which disappears on deeper pressure, by the discovery of other painful points in the course of the nerves affected, by the absence of all symptoms referable to the stomach, and by the co-existence of an hysterical diathesis: the distinctive characters of pain affecting the muscles have been already referred to. In the latter class the presence of spinal tenderness, as ascertained by cold, heat, pressure, &c., will generally suffice to indicate (in the absence of symptoms referable to the abdominal viscera) the nature of the affection.

(d) Pain in the transverse colon frequently stimulates that arising from the stomach. It is often associated with an amount of flatulent distension which may add greatly to the difficulties of diagnosis of its seat. There is, however, generally a distinct difference, especially on gentle percussion, between the notes to be elicited from the two organs; that arising from a distended colon being the less prolonged, and having a higher pitch. Pain also from this source is seldom so much felt at the ensiform cartilage as in the right or left hypochondriac regions, and it frequently extends in the direction of the sigmoid flexure. It is also associated with colicky pains and with irregular contractions, which may be seen or felt by the hand, together with borborygmi, distension, and other signs of intestinal flatulence, and with migratory pains in other parts of the abdomen.

B. Movement.—Of the functional disturbances in the movements of the stomach, spasm has been already alluded to as a cause of pain. Vomiting, the other derangement coming under this head which most demands attention, may, like pain, originate from causes intrinsic or extrinsic to the stomach, and it may be conveniently classified according to its origin from sources of peripheral irritation either of the stomach or of other viscera, or from disturbed action of the central organs of the nervous system.

As a reflex act it may arise from irritation of the nerves supplying the stomach and fauces, or of other and distant parts which have no direct apparent connexion with these in their sources of nervous supply. The former scarcely need further illustration, since they are familiarly known, and will be repeatedly alluded to hereafter. The

1 Bamberger, Krank. Chylopoietischer Syst. 171.
2 This is, however, a peculiarity of some forms of pain undoubtedly originating in the stomach, and which cannot, therefore, be relieved upon.
3 Hilton, Lectures on Rest and Pain, pp. 79, 80.
latter require to be borne in mind as sources of error in diagnosis regarding the origin of this symptom. Among the disorders of other organs which most commonly produce it are those of the uterus and ovaries, and of the testicle, renal and biliary colic, hepatic abscess, peritonitis, ulcerations, invaginations, hernia, or other obstructions of the intestines, epiploic hernia, and paroxysmal cough.

Vomiting from cerebral causes may arise from cerebral anaemia, and also from nearly all the known disorders or mechanical injuries of the brain, independently of the part affected, as well as from some whose nature is less distinct, as in some cases of commencing paralysis after diphtheria. It is a common symptom at the commencement of apoplectiform attacks in elderly people, and it occurs with great frequency in tubercular meningitis.

Certain toxic agents acting through the nervous centres also produce it, and in the same category must be placed the influence of many disordered conditions of the blood, as in uremia and in the invasion of the acute diseases, and in the cold stage of intermittents.

It is also associated with other and purely functional disorders of the nervous centres, as from shock or fright. It is a frequent accompaniment of the hysterical diathesis, to which more special allusion will be made hereafter. It is easily excited also by affections of the senses, as by severe pain, by objects nauseous or disgusting to the sight, taste, or smell, or even by the idea of these, and by a bright light. The sight of objects in motion also produces the symptom in some people. Swinging movements of the body are also capable, when continued, of giving rise to vomiting, with various degrees of facility in different persons; and both of the last-named causes probably combine to produce the phenomena of sea-sickness, which is in many very closely imitated by the effects of riding in a carriage, and especially by riding backwards.

The diagnosis of vomiting arising from disease of the stomach from that depending either on cerebral or on reflex causes is at

---

1 The irritability of the stomach in affections of the female genital organs, so constantly illustrated by the state of pregnancy, should, in cases of doubtful origin, never be overlooked by the practitioner. In a case related by Gooch, from Denman's Experiences, vomiting followed each attempt to pass a ligature round an inverted uterus, and ceased as soon as the ligature was slackened. Dis. Women and Children, New Syd. Soc. p. 137.

2 Budd, Stomach, 3. Ib. p. 192.

3 The author has known severe vomiting depend on this cause.

4 Chomel, Des Dyspepsies, pp. 133, 134.

6 Abercrombie's Second Form of Apoplectiform Attack.

7 Jenner on Diphtheria, p. 42. In these cases, from the simultaneous affection of the heart, there was reason to believe that the roots of the par vagum were probably affected.

8 Tobacco, digitalis (Clarus, Arzeneimittelhrehe, 596; Andral, Path. Intern., i. 147), opium, cyanide of potassium applied externally (Andral, Clin. Méd., v. 270), lobelia, and the vapour of chloroform. Majendie's experiment, by which vomiting was induced in a dog after a bladder had been substituted for the stomach, by means of injection of tartar emetic into the veins, would appear to show that this agent has a similar effect.

9 Typhoid fever, pneumonia, and scarletina are among the most common of these.

times very important, lest a grave disease in some other organ be overlooked through the attention being directed solely to the symptoms presented by the stomach. The criteria of the latter class are often by no means distinct, and the origin of the symptom can only be elucidated by a careful investigation of the circumstances in which it originates. In some of these cases, however, the vomiting resembles that arising from cerebral causes.

Among the chief differences observable between vomiting arising from the latter cause and that depending on irritation of the stomach, the following deserve attention.

Vomiting arising from disorder of the stomach is usually preceded by nausea, and is attended by more or less epigastric pain and oppression and uneasiness, together with other signs of derangement of the digestive system, such as constipation or diarrhoea, a loaded tongue, and thirst. Moreover, the nausea and vertigo which precede or accompany it are usually relieved by the act of vomiting.

Vomiting from cerebral causes is often unattended with nausea, but vertigo or pain in the head are very common, and both these symptoms are rarely relieved by the vomiting. There is commonly no epigastric pain\(^1\) or uneasiness. The tongue is often clean.

Other cerebral symptoms are also usually superadded, such as pain, diplopia, or indistinctness of vision and alteration of the pupils, confusion of ideas, loss of memory, anaesthesia, or some form of paraesthesia, cramp, convulsions, paralysis, or coma.

The indications obtainable from the matters vomited vary considerably in their diagnostic value. Blood will be more fully considered hereafter. Food may either be returned unaltered, as in some cases of nervous vomiting, where it is ejected almost as soon as it is swallowed; or it may present evidences of fermentative changes, varying with the length of time during which it has been delayed in the stomach, but which more particularly affect the starchy substances. These are in some cases changed into a tenacious glutinous material, resembling some of the products derived from the lactic acid fermentation,\(^2\) while in others they are found to be frothy from the evolution of carbonic acid, and associated with the formation of large quantities of the torula cerevisiae.\(^3\) In other instances alcohol\(^5\) has been found, together with amyllic alcohol and the butyric, lactic, and acetic acids. These changes occur in the most extreme degree when the food is delayed in the stomach by obstructions at the pyloric orifice, under which circumstances the sarcina ventriculi of Goodsir is found in the

---

1 Exceptional cases occasionally occur. Some of these have been quoted by the author in a former work. Diagnosis and Treatment of Dyspepsia, p. 60.
2 Disorder of the stomach is often accompanied with severe cerebral pain, especially under the form of sick-headache, which is sometimes associated with much intolerance of sight. It is, however, usually relieved by vomiting.
4 Ibid.
scum which rises on the surface. This growth assumes the form of oblong plates, divided by dissepi-
ments into four secondary, six-
teen tertiary, and sixty-four ele-
mentary square cells, which measure from \( \frac{1}{17} \) th to \( \frac{1}{10} \) th of an inch along each of their sides; and from the arrangement thus described it received the name of sarcina or woolpack, given to it by its discoverer.1

Though, however, for the reasons just stated, its appearance is most common in cases of pyloric obstruction, it is by no means pathogno-
monic of this condition. It has been found in many other diseases of the stomach, occurring in several cases of direct injury to this viscus,2 and in some instances where digestion was probably affected by impaired innervation, and when no lesion of the organ has been discoverable.3 It occurs also in cases of catarrh of the stomach,4 and probably in other conditions when fermentative action is constant or frequent, though it appears to be doubtful whether it is capable of causing this action.5 Its generation in the stomach appears to be mainly associated with an acid form of fermentation (Budd); but it has been found in other tissues and fluids of the body,6 though the conditions of its formation under these circumstances have not been fully explained.

Independently of food, other matters vomited are sometimes of value in the indications which they afford of disease of the stomach. Thus mucus is almost invariably an evidence of catarrhal conditions; while with respect to other fluids, whether acid or alkaline, the chief conditions under which they are secreted are alluded to under the heads of Pain and Acidity.

Bile commonly appears whenever the straining is long and violent; it is not therefore indicative of any special disease, though its presence in the stomach serves at all times to retard the digestive process.

5 Virchow, Archiv. i. 271. Kühne, Lehrbuch der Phys. Chemie, p. 59, says that he has kept sarcine with vomited matters, and also with solutions of sugar, for days, without the slightest development of gases ensuing.
6 In the lungs, by Virchow, Froriep. N. Notizen, 1846, No. 825; Archiv für Path. Anat. x. 401; also by Zentker, Zeitsch. Rat. Med. N. F. iii. 117. In the urine by Heller, Archiv Chem. Microscop. 1847, 1852. Also in the pelvis of the kidneys and in the bladder by Mr. Hepworth, Microscop. Journ. v. 2, 3; and in the bile by Dr. Lionel Beale (quoted by Dr. Budd, loc. cit.).
Puś, as such, is not formed in the stomach, except in those rarer instances where suppuration takes place in the submucous coat; and its presence in vomited matters is therefore generally indicative of its having been formed in the esophagus, or that it has entered the stomach from some source external to that organ.

Vomiting of foreign products, such as worms or echinococci, are among the rarities of medical literature: in the case of the latter their appearance would be indicative of a communication having been established between the cavity of the stomach and an echinococcus cyst in the liver.

It is believed by some practitioners that cancer cells can be distinguished among the products of vomiting when the disease affects the stomach. I know of no authentic instance where such an observation has been made of an indubitable kind; while the improbability that any portion of a cancer would be separated in a condition in which its cells would still present their distinctive characters, coupled with the fallacies presented by the appearances of swollen epithelial cells from the stomach, or from the buccal, pharyngeal, or esophageal surfaces, should cause such evidence to be received only with the greatest care and caution.

Dr. Quain and Mr. Beardsley have, however, recorded a case where a polypoid growth having all the characters of those ordinarily found in the stomach was ejected entire; but the pedunculated growth of these formations would allow of their separation with much greater ease than in the case of cancers, portions of which are ordinarily only removed by sloughing processes, which destroy the characters by which they can be recognised.

Faecal vomiting can as a rule only occur under conditions either of direct communication of some portion of the intestine (usually the colon) with the stomach, or as the result of obstruction to the passage of the feces through the intestines. Briquet has, however, recorded a case, observed under circumstances when imposition appears to have been impossible, of an hysterical patient who speedily vomited matters introduced into the rectum.

The contents of the stomach are sometimes ejected by the simple contraction of its coats, without the participation of the abdominal and thoracic muscles; and to this process the name of eructation has been applied. Gas is very commonly ejected in this manner, and it is often accompanied by small portions of food. Acid or neutral fluids are also frequently thus brought into the mouth. The vomiting of infants very closely resembles this process, as from the shape of

---

1 See a case of this nature, where pus was vomited from a fistulous communication between the esophagus and pericardium, Dr. Chambers' Indigestions, p. 175. The same author says that he has seen this product in matters vomited in cases of cancer of the esophagus and cardia.

2 Lebert, Traité des Maladies Cancereuses, p. 304, says that these have been observed by M. Schoenlein (Qy. Schönlein), but gives no further particulars.

DISEASES OF THE STOMACH.

795

the stomach in infancy its contractions have a greater tendency to force food through the cardia than is the case in the adult, when it is propelled into the fundus. This effect under any circumstances is commonly due to undue irritation or to excessive distension of the organ, and therefore is very common when food is swallowed without due mastication. In some persons the continuance of the habit has led to a habit of quasi-rumination, the food thus brought up being subjected to a second mastication before it is swallowed.1

C. SECRETION.—Alterations in the secretions of the stomach may be classified under the categories of excess, deficiency, or perversion.

It must, however, be remembered that secretions both of an acid and also of an alkaline character are normal products of the mucous membrane: the former being furnished by the glands situated in the fundus and body of the organ, which are lined by a spheroidal epithelium, and which furnish the true gastric juice; the latter by those of the pyloric region, whose epithelium is columnar, and whose products, having the characters of ordinary mucus, possess little or no digestive properties.

It is important, however, that it should be borne in mind that the presence of an excessive amount of free acid in the stomach is in by no means the majority of cases due to excessive secretion from its coats, but depends with great frequency on unnatural changes in the food; so that it is necessary at all times to distinguish acidity from fermentation from acidity from secretion.

The former is due to all causes tending to delay or prevent the normal changes which the food undergoes in the digestive canal, and hence is a common symptom of indigestion, however produced; and it often appears in its most intense forms when the natural secretions are diminished, or when their amounts do not present their normal relation to one another. Hence acidity from fermentation may arise (1) in all cases when digestion is delayed from imperfect supplies of the gastric juice; or (2) when the food is merely retained in the stomach by obstructions of the pyloric orifice; or (3) when food in a state of fermentation is introduced into the stomach in quantities sufficient to neutralize the antiseptic action of the gastric juice; or (4) when mucus possessing a catalytic action is secreted by the stomach; or (5) when, from disordered conditions of the salivary and buccal secretions, the proper changes are not effected during mastication in the amylaceous portions of the food; or (6) when in otherwise healthy subjects an excess of starchy or amylaceous substances is taken with the food. The results of this action are shown in the formation of acid products, usually derived from the starchy and saccharine elements. The acids so produced, and which are often formed with great rapidity, are chiefly the lactic, butyric, and acetic, which appear in great abundance under such circumstances: and further evidence of the fermentative character of the process is seen in the evolution of gas, which consists

1 For further details on this subject see Copland's Dictionary, art. "Rumination."
principally of carbonic acid and volatile carbo-hydrogen, while sulphuretted compounds appear when articles containing this element in excess have been taken with the food.

Flatulence and acidity are therefore almost constant results of imperfect digestion, though the evidence of the one is sometimes more distinct than that of the other. Flatulence, however, may appear chiefly in the intestines, as the result of imperfect changes which the food has undergone in the mouth and stomach. Similar fermentative changes, evidenced by distension of the bowel and by frothy and pultaceous stools, may also result from defective metamorphosis of the food in the lower portions of the intestinal canal, arising from deficient supply or abnormal condition of the secretions of the intestines, the liver, and the pancreas, as well as from conditions impeding the absorption of the peptones.

With respect to alterations occurring in the secretions—

1. An excessive secretion from the glands of the stomach may affect either of the classes before alluded to, and may furnish fluids either of an acid or an alkaline character. The circumstances under which these different formations occur are not in all cases accurately known to us, but in some cases we are able to distinguish the cause of an arrest of the one and an excess of the other. Thus, under the influence of inflammatory action, or in many cases of excessive physiological stimulation, the acid gastric juice is either completely arrested or greatly diminished in amount, while there is an undue formation of mucous secretions of an alkaline reaction.

The most common causes of excessive secretions are, however, those of nervous origin, though the nature of the influences under which they thus originate are only imperfectly understood; and acid and alkaline secretions appear to be produced by different patients under circumstances apparently similar.

One form of disorder in which alkaline or neutral fluids are furnished in great quantities has received the distinctive name of pyrosis, from the burning sensation at the cardia which often precedes its ejection. It occurs endemically among the poorer classes of Scotland and of certain northern countries, and is, under these circumstances, attributed to the effects of an irritating or of an innutritious and insufficient diet. It is met with, however, occasionally in the wealthier classes, and in nervous females, when there is no evidence of organic disease; and it also is an accompaniment of ulcer and cancer of the stomach.

The fluid thus ejected is clear, often insipid and neutral in reaction, and it is frequently brought up in considerable quantities by an act of regurgitation, sometimes without any effort at retching, though

1 Dogs in which a biliary fistula has been established pass a large amount of offensive flatulents per annum.

DISEASES OF THE STOMACH.

it may occasionally be expelled by vomiting. It has been considered by some authorities to consist merely of saliva which has been swallowed, an opinion which has received some support by the observation of Frerichs, that it sometimes contains a considerable amount of sulpho-cyanide of potassium. It appears, however, to the author, that this admixture may be due either to some saliva swallowed or mingled with the fluid in the act of ejection. Patients also who are subject to the affection are by no means conscious of an amount of salivation at all proportionate to the quantity of fluid brought up from the stomach; and it would therefore appear more probable that the larger proportion originates from an altered secretion of the fluids of the stomach.

Though the reaction of this fluid is very commonly neutral, yet occasionally highly acid fluids are ejected, under circumstances similar to the foregoing, and when, from their character and reaction, it is probable that they have been secreted by the stomach. Some observations made by Dr. Pavy on these fluids tend to show that, while the acid fluids possess digestive properties, the neutral fluids have, even after acidulation, very little of this power.

Acid fluids are also ejected under other circumstances of nervous derangement, chiefly of a reflex character, as in the vomiting of pregnancy, or from diseases of the uterus, or in that which takes place in attacks of renal and biliary colic. M. Chomel has described another class, when, after attacks of cholera, vomiting of acid matters continued with great obstinacy, and in some instances proved fatal. The nature of these cases is, however, obscure. The fluids vomited do not appear to have been chemically examined, and it may be considered doubtful whether the acidity observed was not derived from rapid fermentative action in the food, caused by the unhealthy condition of the stomach, rather than from any direct secretions from the mucous membrane.

2. Perversion of the secretions of the stomach are known to occur in the course of uremia and diabetes. In the former case either urea or carbonate of ammonia are found in the secretions of the stomach. Bernard noticed that under these circumstances the secretion was still acid, and also that, instead of being evoked solely by the stimulus of food, it became more or less continuous,—a fact which may assist to explain much of the disturbance of the functions of the stomach which occurs in the course of this affection. In diabetes sugar is sometimes found in the secretions of the stomach; but we are not acquainted with any special effect which this admixture has upon the act of digestion.

It is not improbable that other alterations may occur in the composition of the gastric juice in certain blood diseases; but of the nature of these we are as yet ignorant. The possibility, also, of changes of a similar nature arising in the course of affections of the liver and pancreas is a subject rather of hypothesis than of direct proof.

3. Arrest or diminution of the secretion of gastric juice takes place under so many and varied conditions, that it is impossible to do more than briefly summarise them in this place, and they will be more fully treated of in relation to the special diseases of the stomach. Thus sudden moral or physical impressions, especially those of a depressing nature, exhausting mental and physical efforts, and many diseases of the nervous centres, have all this effect in common. Inflammatory processes, as already stated, produce the same results to an extent proportioned to the intensity of the process: weakening diseases and physical exhaustion, or privation of food or water, similarly diminish the amount of the secretion. Digestion also may be arrested, probably from reflex causes, through disordered conditions of the lower part of the intestinal canal,¹—as from constipation, the presence of worms in the intestines,² or even from enemata of cold water administered while digestion is proceeding; and the due appreciation of the influence of these and similar aetiological circumstances is of the utmost importance in arriving at a correct understanding of many of the causes of an imperfect performance of the digestive act.

D. Digestion.—Imperfections in the due changes of the nitrogenized elements of the food by the gastric juices in the cavity of the stomach constitute the most important of the disorders in the functions of this organ.

To these defects the terms of indigestion, dyspepsia, or aepsia, have been applied.

In treating, however, of such aberrations among the functional disorders of the stomach, several points require to be distinctly understood. In the first place, indigestion may result from derangements in the action of other parts of the gastro-intestinal canal, which contribute to the metamorphosis of the different constituents of alimentary matter. Disturbances in the digestive act may thus be caused by defects either in the quality or amount of the secretions derived from the buccal and salivary glands, and also from those of the pancreas, the liver, and of the intestines, affecting either the starchy, saccharine, or fatty elements of the food, and also of the protein substances which have escaped the action of the stomach.

Secondly, similar derangements may depend not only on disorders primarily originating in these organs, but may result directly from the food supplied being either of a nature incapable of being affected

¹ Trousseau, Union Médicale, 1857. ² Bean, Dyspepsie Vermineuse.
DISEASES OF THE STOMACH. 799

by their secretions, or from its being presented to them in a form in which their action is with difficulty exerted.

Thirdly, it is also to be borne in mind, that the direct effects of this imperfect elaboration are such as are more or less common to the whole class of indigestions, and consist of certain fermentative or putrefactive changes in the food, to which some allusion has already been made: nor have we any certain and practical criteria by which under ordinary circumstances we can distinguish from the nature of these intrinsic changes in the food the special source of the derangement in which they have originated,¹ since the imperfect performance of any one of the functions of the digestion usually disturbs the actions of those next in physiological sequence, and often, but in a less, though varying, degree, reacts injuriously upon those which precede it in the order in which the food is presented.

Fourthly, when we confine ourselves to indigestion as met with in the stomach, which is perhaps the most important organ in the series, we find that this disturbance may be produced by nearly every disorder to which the stomach is liable; and that its source and origin cannot, as such, be discovered solely through imperfect changes in the food, but must be mainly determined by various concomitant circumstances, which may or may not be readily discoverable.

Hence when viewed as a whole the indigestion of food can only be regarded as a symptom revealed by a series of phenomena, some of which are the primary results of the imperfect changes in the alimentary substances, while others are the more or less remote effects of these. The former, although varying within certain limits, according to the nature of the food, are common to all forms of indigestion, however originating; but though of great importance as indicating the existence of this state, they are yet only secondary in diagnostic value to those symptoms through which the state of the stomach in which they primarily originate can be distinguished, and on the recognition of which any successful attempt at a pathological classification and consequent diagnosis must depend.² The distinction is not indeed always an easy one, since the acids and gases produced by the alterations in the food almost constantly give rise to other secondary disturbances in all the chylopoietic viscera, which in some cases, and especially through the pain which they produce, are liable to be confounded with those originating in morbid states of these

¹ The author alludes to the more ordinary forms: the presence of the excess of fat, of the absence of bile in the feces, would of course respectively point to deficiency of the pancreatic or hepatic secretions, or of imperfect absorption by the lymphatics.

² Much of the difficulty and uncertainty in the treatment of dyspepsia has arisen from its being regarded as an individual disease, referred by one class of observers to atony (Cullen), by another to inflammatory conditions (Broussais), and by a third to disturbed innervation of the stomach (Karras). The confusion has been further increased by many writers, especially of the French school, introducing sub-varieties according to the prominence of individual symptoms, which, however, can never serve as a sound basis of classification. A further account of these opinions will be found in the Introduction to the author's work, "Diagnosis and Treatment of Dyspepsia." The most complete historical account of the views entertained respecting disorders of the stomach is that by Dr. T. J. Todd, art. "Indigestion," Cyc. Pract. Med. iii.
organs. Still, however, the separation of these classes is practically so important, that it is desirable as far as possible to maintain it, though it may be difficult to determine in which category any single symptom is to be placed when regarded apart from the whole group with which it is associated.

In such a mode of arrangement the symptoms arising directly from abnormal changes in the food,—such as acidity, flatulence, eructation, distension of the stomach and intestines with gas, borborygmni, and alterations in the fecal evacuations,—serve as evidences of abnormal fermentative processes, the nature, causes, and effects of which have been already discussed. Those, on the other hand, which may be regarded as more direct signs of disturbance of the stomach (though sometimes only resulting from the former) are weight, uneasiness, sinking, craving, emptiness, or pain of different degrees of intensity, appearing either when the stomach is empty, or at variable periods after the ingestion of food. With them also must be placed affections of the appetite and thirst, either on the side of excess, or deficiency, or perversion; and in the same category must be included symptoms arising in parts which are more remote, but yet forming part of the gastro-intestinal canal, such as the tongue, mouth, salivary glands, and fauces. Or the condition may only be revealed by symptoms appearing in other organs, the connexion of whose disorders with that of the stomach is of a secondary nature, and which may be enumerated according to the parts in which they occur, viz.:—

**Disturbances of the nervous system,** indicated by neuralgic pains of the thoracic and abdominal muscles, weakness and weariness, or painful aching in the limbs; by headache, vertigo, perversions of vision, impaired intellectual activity, loss of memory, depression of spirits, anxiety, fear, morositiy or irritability of temper; or by the various forms of hypochondriasis, melancholia, or hysteria; or, in some instances, by convulsive attacks.

**Alterations in the urinary secretions,** consisting sometimes of excess of watery fluids, or of urea; sometimes of diminution of the total amount, associated with lateritious sediments;—or of variations in its reaction, which sometimes shows an excessive acidity, and at other times is alkaline at the moment of emission, and containing in the latter case an undue amount of phosphates;—or in its contents, which may be abnormal, and exhibit albumen, sugar, cystine, or the salts of oxalic acid.

**Disturbances in the generative organs,** evidenced by perversions of the menstrual function, or by leukorrhoea, in the female; or by impotence, priapism, or spermatorrhoea, in the male.

**Alterations in the skin,** manifested sometimes by febrile heat and suppression of perspiration; in other cases by general coldness and chilliness, especially of the extremities; or by perspiration on very slight exertion;—or by alterations in its colour or texture, which may be earthy or sallow in tint, or dry and coarse;—or by various
eruptions, among the most frequent of which are erythema, eczema, herpes, acne, impetigo, lichen, or urticaria.

*Alterations in the circulation,* evidenced by frequent palpitation, occurring either spontaneously or on very slight exertion; by irregular action and intermission in the rhythm of the heart's contractions; and by weakness or excitability of pulse.

*Alterations in the respiration,* as shown by dyspnœa, occurring spontaneously, with a sense of load at the chest, or on slight exertion; or by cough, usually dry; or by asthmatic paroxysms.

*Alterations in the general nutrition,* as shown by anaemia; by emaciation, affecting all the tissues, but especially seen in certain parts, as in greyness or loss of the hair, caries of the teeth, retraction of the gums, and incurvature of the nails, which are thin and friable; or by excessive liability to inflammation, from slight causes, of the mucous membranes, and particularly of the conjunctivæ and throat. To which we may add, in persons predisposed to such affections, a liability to gout or rheumatism, or to renal or pulmonary affections, so that very common consent pulmonary phthisis has been frequently regarded as a consequence of long-continued derangement of the digestion.¹

These symptoms are very variously grouped, and sometimes occur with great irregularity; and it is important to note that those affecting the stomach may in some cases be far less prominent than others which, though occurring in distant parts, are still valuable evidence of the primary disturbance which exists in the functions of digestion.

And it must further be remarked, that many of them are not referable to the disorders of the stomach alone, but to perversions of the functions of the lower portion of the intestinal canal.

The secondary disturbances in the nervous system belong in an almost equal degree to derangements of the stomach and of the intestines, for as Beaumont has shown that vertigo was a common effect of irritation in the former, so, on the other hand, clinical experience is constantly demonstrating that this symptom is equally produced by flatulence and other derangements of the functions or condition of the latter. Many also of the moral and emotional disorders, and particularly depression of spirits, irritability of temper, and hypochondriasis, though sometimes undoubtedly originating from an independent and primary disorder of the nervous centres, appear often to result directly from the condition of constipation so frequently present; and though the origin of this is threefold, arising from imperfect changes in the food, diminished peristalsis of the muscular coats of the bowels, and from deficiency of secretion from the mucous membrane, the liver, and the pancreas, it is probably in a great measure to the last-named cause, which must materially affect the composition of the blood, that the nervous phenomena of this class are mainly attributable.²

¹ See especially Schmidtmann (Summ. Obs. Med. iii. 203), Wilson Philip, and Dr. Hughes Bennett. This subject will be more fully dwelt upon hereafter.

² This subject has been fully treated of by Dr. Chambers, Lectures chiefly Clinical.

VOL. ii. 3 F
It is therefore of importance for the cure of indigestion that the pathological condition in which it originates should be recognised, and also that the causes of such disorder should be discovered, and if possible removed. It therefore appears desirable briefly to summarise the chief of these, reserving a fuller description of their effects and mode of action for the chapters devoted to special disorders.

As a healthy performance of the functions of the stomach depends on the harmony of the relations between the stomach and the food, our classification of the causes of indigestion may be conveniently divided into (1) those which depend on unsuitability of the food, and (2) those which affect the physiological functions of the organ.

1. Dyspepsia from unsuitability of food\(^1\) may depend on defects in the quality or the amount of the ingesta.

\(a\). Defects of quality may arise through \((a)\) aberrations in the proper proportions of the nutritive elements; among which may be enumerated excess or deficiency of any of the normal ingredients, saccharine, amylaceous, proteinous, or oleaginous, or of some of the naturally indigestible materials which form a part of all human diet, and also excess or defect of sapid substances,\(^2\) which, on the one hand, favour the secretion of the digestive fluids, or may when in undue amount exert an injurious action on the tissues of the stomach.

\((b)\) The food may be presented in an indigestible form through defects of cookery,\(^3\) or through imperfect mastication and salivation,\(^4\) or from its having undergone fermentation or putrefaction, or other changes which prevent or arrest the normal functions of the alimentary canal.\(^5\) Alcohol in excess, or in too concentrated a form, retards the action of pepsine. Ice also, or large draughts of cold water, and diluents in excess, diminish the secretion of the gastric juice by lowering the temperature of the stomach, or impair its efficacy by undue dilution.

In the same category may be placed idiosyncrasies which certain persons exhibit against particular kinds of food\(^6\) ordinarily reputed wholesome.

---

\(^{1}\) The author is compelled, for the sake of brevity, to present this portion of his subject in a very condensed form. For a fuller explanation of this branch of the subject he would refer the reader to Paris on Diet, Brinton on Food, Parkes's Practical Hygiène, or to a summary of these subjects lately published by him, Diagnosis and Treatment of Dyspepsia, pp. 71 et seq.

\(^{2}\) Under this head are included all condiments; which generally are of value in exciting the secretions of the saliva, and hence favouring the digestion of starchy foods. They have less influence on the secretions of the stomach (see Atomic Dyspepsia), but appear to be useful in some cases when digestive power is enfeebled by what may be relatively termed natural causes, as from old age, or the effects of hot climate. It is probable, however, that agreeable impressions made upon the sense of taste favour the secretions of the gastric juice.

\(^{3}\) Especially apparent in the amylaceous substances.

\(^{4}\) The last named of these causes may arise solely from the former, or from disordered conditions of the salivary and buccal secretions, which may be defective or abundant, but too watery or acid.

\(^{5}\) Impure water, especially such as contains an excess of calcareous or magnesian salts, may be included in this category. See Parkes's Pract. Hygiène.

\(^{6}\) Milk, eggs, cooked butter (Chomel, Dyspepsies, p. 8), mutton (Sir J. Watson, Princ. Pract. Physic, ii. 457), honey (Andral).
B. Errors in the amount of food, particularly on the side of excess, are among the most common causes of indigestion.

The secretion of the gastric juice, at least in a healthy state, seems in some yet unexplained manner to be proportioned to the amount of material required for the repair of the waste of the system; and in the majority of cases food introduced in excess of this acts as a foreign body, and undergoes fermentative or putrifying chemical changes; or in the comparatively few instances where these do not ensue, and the food is digested and assimilated, it gives rise to obesity and other evils, on which it would be beyond our province to dwell.\(^1\)

Irregularity, and especially too small intervals between the periods of meals, involving the taking of food before the preceding supply has been digested and removed from the stomach, is another most frequent, and, when indulged, a necessary, source of indigestion. It is well known that the digestive powers of a given amount of the gastric secretion are limited, though the absorption of the peptones already formed, while the pepsine is retained in the stomach\(^2\) by the dialytic action of the mucous membrane, greatly extends the duration of its action. It is nevertheless evident that, if as much food has been taken at one meal as the stomach can digest, the addition of a fresh supply before the former has passed from its cavity will only delay the changes which the whole has under such circumstances to undergo. Some food has been shown by Busch's observations\(^3\) to pass rapidly into the duodenum; but a period of nearly five hours\(^4\) must elapse before the whole of a full meal has passed through the pylorus; and in addition to this it is most important that a period of rest varying from one to two hours should be allowed to the organ. There are few medical men who are not acquainted with patients who allow a much shorter interval than this between each of the three principal meals of the day; and the effects of such a system are as injurious as, and practically are identical with, those of excessive eating; though it is often difficult to convince those who indulge in it of the error in their habits.\(^5\) Many delicate people think that it is necessary to eat often to keep up their strength, but fail to recollect that when meals are taken frequently each should be small, and that when meat is eaten three times daily in tolerable quantities, the addition of milk, eggs, wine, and beef-tea, in the intervals, destroys the beneficial effects of all. It must be borne in mind also, in estimating the effects of a given diet on the health of a patient, that the amount required varies with the expenditure of the system, and that a sedentary life, whether habitual or suddenly entered upon, necessitates a reduction of the food taken, if health is to be maintained. The breach of this rule is often observed, and the ill effects produced

---

5 See a case in point by Sir T. Watson, loc. cit. ii. 450.
on those who, having previously lived an active life, retain their customary habits of eating in periods of enforced or voluntary idleness, has long been well known. Indeed, in all dyspeptic derangements it is important for the practitioner to be on his guard against possible errors in diet, and especially against those which, having become a question of habit, and of relative rather than absolute quantity of the food taken, are the more likely to elude both his own and his patient’s observation.

Deficiency of food, though often mentioned among the causes of dyspepsia, and unfortunately holding among these but too prominent a place in the poorer classes of society, acts probably only in an indirect manner on the digestive powers by weakening those of the whole system. In these cases the food is also too frequently of innutritious quality, and the sloppy tea and bread which forms so large a proportion of the diet of many of our hospital patients is a constant source of the flatulent disturbances from which they suffer, and which, under the circumstances in which they are placed, are often very difficult to relieve. The effects of starvation, and the dangers of indiscriminately giving nourishment in these cases, are familiar to all readers of physiological works, and will be again referred to.

2. Causes of indigestion referable to pathological states of the stomach may be referred to abnormalities either in its secretions, or in its movements, or in the absorption of the peptones.

With disorders in the last named of these functions we are only imperfectly acquainted, but it is probable that under certain circumstances their unfavourable influence is by no means inconsiderable.

Causes affecting the secretion of the gastric juice are those which play the most important part in this category. They have been already in part alluded to, and may be briefly summarised in the following scheme:—

I. CAUSES TENDING TO PRODUCE DEFICIENCY.

A. Organic

1. Inflammatory conditions, which reduce the amount of peptic fluids, but increase the mucus secreted.
2. Congestion.
3. Degeneration and atrophy of the secretory glands.
4. Pyrexia conditions of the system.

B. Inorganic

1. General weakness.
2. Disordered blood states.
3. Disorders of liver and pancreas (f).
4. Agencies operating through the nervous system—moral, intellectual, shock, exhaustion, invasion of acute diseases, narcotic remedies.

II. CAUSES TENDING TO PRODUCE EXCESSIVE OR PERVERTED SECRETIONS.

1. Ulcer and cancer.
2. Inorganic agencies operating through the nervous system, chiefly sympathetic, and depending on irritation of other organs, as the mouth, fauces, intestinal canal, liver and gall-bladder, kidneys, and uterus.
3. Disordered blood states.

1 A case of affection of the lymphatics, in what appears to have been a simple ulcer of the stomach, is recorded by Andral, Clin. Méd. ii. 110.
Diseases of the Stomach.

Derangements in the movements of the stomach may injuriously affect digestion either by their deficiency, irregularity, or excess.

Deficiency of movements may result from weakened muscular power, from dilatation, and from paralytic conditions induced either through impaired innervation, or inflammation of the peritoneal and possibly of the mucous coats.

Irregularity of contraction may result from obstructions of the pyloric orifice, from thickenings, indurations, malformations, or displacements, or adhesions of the stomach to adjacent viscera, or by simple pressure on the organ when distended with food, such as is exercised in certain trades, or by tight stays, or by diseases of the liver.

Excessive contractions induced by undue nervous excitability or by minor degrees of inflammation tend, independently of vomiting, to expel the food too rapidly from the stomach, and in the same category must be placed the effects of destruction by disease of the pyloric ring.

It will be seen from the foregoing that indigestion is in probably a considerable majority of cases the result of pathological conditions of the stomach which vary widely from one another in their essential nature and in their aetiological relations, while no single category can be erected embracing for any practical purposes the different varieties of the disorders so produced in the functions of the stomach. Nor can any convenient classification according to its causes be adopted, since even in those forms which arise from imperfections in the manner in which the food is presented the result is frequently a complex one, and secondary effects of an inflammatory nature are often thus produced in the mucous membrane of the stomach which surpass in importance of intensity and duration the primary disorder of function. A classification therefore on a pathological, and as far as possible on an anatomical, basis, is the only one which can conduces to certainty of diagnosis, or to scientific principles of treatment.

The main lines of division which will be here adopted will be to distinguish the non-inflammatory dyspepsias from those which depend on inflammatory changes; the disorders produced by ulcer and cancer standing again in a distinct and separate category. In the first-named class will be included dyspepsias from simple weakness, whether general or local, and with these will be classed those forms resulting from atrophy, or from simple degeneration of the secretory glands, to all of which, collectively, the term of atonic dyspepsia will be applied.

Disorders in the functions of the stomach distinctly referable to impaired innervation will form a separate category, and the inflammatory varieties will be considered under the heads of the acute and chronic forms.
II.—Atonic Dyspepsia.

Atonic Dyspepsia, which corresponds to the Dyspepsie apyrétique or asthénique of Broussais, may be defined as a disorder of the digestion, almost invariably chronic in its course, unattended by fever, and rarely, when uncomplicated, by abdominal pain; whose existence is indicated by weight, uneasiness, and languor following the ingestion of food, together with a general depression of the vital powers; and whose causes are, in a great measure, identical with those which induce a general impairment of the nutrition and the powers of the whole body.

Ätiology.—Among the predisposing causes of atonic dyspepsia may be mentioned hereditary disposition, the evidence of which, though not resting on absolute numerical data, is so well attested by numerous observers, and, the author may mention, by many instances within his own knowledge, as to be, he believes, incontestable. Age exercises an important influence also in determining this disorder, the diminution of the power of the stomach at advanced periods of life being, in many instances, as apparent as is that of the muscular or nervous system—a fact which it is of great importance to recollect in the hygienic treatment of elderly people. Nor should the relatively limited digestive powers of the opposite extreme, in early infancy, be forgotten, and where, in spite of its great assimilative power, the capacity of the stomach for acting on other than a milk diet is extremely small. Aberrations in diet at this period are, however, more frequently the causes of acuter diseases of the gastro-intestinal canal than of simple failure in the metamorphosis of the food.

Impairment of the functions of the stomach may also be more directly produced by states of the system associated with more or less permanent conditions of depressed vitality, such as are sometimes observed from the effects of hot seasons and relaxing climates, associated with any appreciable condition of disease. Still more commonly they are found to result from other causes acting either through the nutritive fluids, or the nervous system, singly or conjointly. In some cases alterations in the blood may be apparent, as in anæmia

1 Some writers, and especially the late Dr. J. Todd, Cye. Pract. Med. iii. Art. Indigestion, describe an acute form of atonic indigestion, in which there is a sudden and total arrest of the digestion, attended with symptoms of irritation of the stomach. It may, indeed, be induced by sudden impressions made on the nervous system during the act of digestion; but unless under these circumstances the contents of the stomach are at once evacuated by vomiting, they prove a further source of irritation, and give rise to a condition of more or less acute inflammatory action, corresponding closely in character to the "Em-barras Gastrique" of the French, and which will be more properly treated of among the "Inflammatory States of the Stomach."
and chlorosis; but in others, even when nutrition evidently suffers, these are less evident. Similar effects on the digestion may be due to exhausting discharges, haemorrhages, leucorrhoea, profuse suppuration, cancer in other organs than the stomach, indulgence in venereal excesses, loss of sleep, sedentary occupations, especially such as are associated with deficiency of light and air, long-continued and depressing moral emotions, and the ennui of insufficient occupation, mental or physical.1

Simple loss of functional power is also produced by causes immediately affecting the stomach, such as excess of fluids taken at meals, especially when drunk warm, or by the abuse of narcotics, and of tea and coffee, by prolonged fasting,2 by the undue use of condiments, which diminish the readiness with which the stomach is affected by its ordinary stimuli, by habitual constipation, and by undue mental or bodily exertion after meals.3

To these causes must also be added the indigestion which occurs in febrile states of the system, in which, as shown by Beaumont on Alexis St. Martin, "food taken in this condition of the stomach (see Pathology) remains undigested for twenty-four or forty-eight hours or more."4

The Symptoms of this form of disorder are:

(a) In the alimentary canal. A sense of weight or uneasiness in the stomach after food, occasioned by the slowness of the digestive process—symptoms which are often protracted for some hours after eating, and are frequently continued up to the next meal. This may afford temporary relief, but is in its turn followed by the same train of discomfort. The weight or uneasiness is in some cases felt behind the sternum, giving rise to a sense of dyspnœa, and at others to a feeling as if some foreign body were present in the oesophagus. It rarely, if ever, amounts to pain, though the condition in some patients, especially in anæmic, chlorotic, or hysterical women, may be accompanied by the complication of intercurrent neuralgia, and in others by an excessive amount of flatulence, giving rise to various degrees of gastrodynia or colic. Tenderness of the abdomen is a rule entirely absent, and pressure not unfrequently gives relief to such pain as may be present, especially when this arises from flatulent distension.

The digestive powers are about equally impaired both for protein and amylaceous substances, but in many cases the former, when in any excess, aggravate this condition; and oily and fatty matters are very prone to disagree, as also do soups and broths.

1 One digests with the legs almost as much as with the stomach.—Chomel, loc. cit. p. 58.
2 The author has known severe and obstinate dyspepsia of the atonic kind induced by the habit of going without food from an early breakfast to a late dinner, and the cause appears explicable by the observations of Bidder and Schmidt, who found that the secretion of gastric juice was markedly diminished after long fasting. Die Verdauungsaefte, p. 41.
3 This is not unfrequently a cause of more acute attacks, and will be referred to hereafter.
4 Experiments and Observations on the Gastric Juice, Combe's edition, p. 92.
Further disturbances appear in the form of flatulence and of eructation, both of gas and also of portions of undigested food, which are often rancid and offensive (probably from butyric acid fermentation). They usually occur some hours after eating—differing in this respect from the acidity following immediately after the ingestion of food which is observed in some cases of nervous origin. The flatulence affects the stomach and bowels in about equal degrees of frequency, sometimes appearing in one more than in the other; but the fermentative changes originating in the imperfect elaboration of the food in the stomach are usually continued in the lower portion of the canal, the functions of which are generally simultaneously impaired.

Impairment of the appetite, though not invariably observed, is a very common feature of all the more marked forms of this complaint. There is frequently a disrelish for food of all kinds, even when exhaustion is felt for want of it.¹

Thirst is generally almost entirely absent, at least to any abnormal degree. In many cases there is a positive dislike for fluids, which not unfrequently (especially when taken with meals, or when nutriment is presented in a fluid form) are found to aggravate the dyspeptic symptoms.² The saliva is said in some cases to be increased (Todd); but this, as far as the author's observation extends, is not the rule in the state now being described.

The tongue is broad, pale, and flabby; pitted at the edges by the teeth; sometimes thinly furred; at others, under conditions of irritation, acquiring a thicker covering—when, however, the other leading characteristics are still frequently observed. The inner side of the lips and gums are pale, flabby, and sometimes spongy, the tonsils are sometimes large, and the uvula and throat relaxed, giving to the voice a thickness and huskiness which the patient sometimes attempts to relieve by hawking and spitting. The breath is not unfrequently heavy and offensive, but not nearly to so marked a degree as in some of the irritative forms.

Constipation forms another prominent symptom; and though primarily resulting from the participation of the secretions and muscular actions of the intestinal canal in the general condition of atony, it aggravates the state of the stomach in the manner before described, and frequently increases the anorexia. The delay of the fecal matter in the intestines also favours the liberation of gas, which, distending the weakened muscular coat, tends still further to diminish its propulsive powers; hence various circumscribed swellings frequently appear in the abdomen, giving a mingled tympanitic and dull resonance on percussion, and borborygmi are heard when by pressure or the irregular contraction of the bowels the gas is moved from place to

¹ A very marked effect of long fasting is familiar to all under the title of having "over-stayed the appetite."

² "Dyspepsie des Liquides" of Chomel. This fact is easily explicable when we recollect that undue dilution greatly impairs the efficiency of the gastric juice, and that in the condition under consideration this secretion is naturally defective in power.
place. These distensions are particularly liable to occur in the course of the colon, especially at its flexures in the right and left hypochondriac regions, where they not unfrequently cause a sense of fulness, tightness, pain, and dragging, which are often, though improperly, referred to the stomach, liver, or spleen. Pain from this cause is also occasionally felt in other parts, especially in the left side, at the insertion of the diaphragm into the ribs, or in the scapular regions.

The evacuations may be sometimes solid, dry, and hard, and often scybalous, or frothy from fermentative action. They are usually paler than natural, and sometimes offensive; but unless an excess of animal food has been taken, this latter character is not so common as in some forms of inflammatory dyspepsia.

Diarrhoea when irritation supervenes may occasionally alternate with the constipation, which is, however, the most prominent symptom.

The circulation is depressed; the pulse is weak, soft, and easily compressible—slow when the patient is in repose, but easily excited on the slightest exertion. Palpitation is common; it occurs irregularly, and independently of organic disease of the heart, and is easily induced by slight exertion, but it frequently arises spontaneously without previous physical or mental effort. It is in many cases directly traceable to flatulent distension, but occasionally it occurs without any distinct evidence of this state. Intermission of the cardiac action, though not so common as palpitation, is also not unfrequent.1

Dyspnoea is a result not only of the cardiac state last described, but frequently occurs independently of it. The feeling is one of load or oppression in the upper part of the chest, and especially across the middle portion of the sternum, impelling the patient to sigh or draw a deep breath, in order to relieve the sensation, which, however, speedily returns. Cough occasionally is caused by an elongated uvula, but the irritative cough frequently described as caused by diorders of the stomach is not usual in this form of dyspepsia.

Except in cases where indigestion is directly due to a febrile state, the course of this affection is singularly free from pyrexial symptoms; the skin is soft, flabby, clammy, and moist, and the extremities are frequently cold, particularly after meals. The complexion is often pallid, sallow, and muddy.

The nutrition suffers more by an aggravation of the anæmia or atony which may be present, than by any direct emaciation—a symptom which occurs more rapidly in the inflammatory and irritative forms.

The urine, as a rule, is but little affected; it is usually clear and copious, and contains but little urea, unless some direct causes of enfeeblement of the constitution, producing excessive waste, are present. Under the latter circumstances the urea may be greatly

1 It may be noted here that a large number of patients who believe, from the symptoms here described, that they are suffering from disease of the heart, are only subject to this form of dyspeptic derangement.
in excess of the normal amount. If irritation supervenes, other
changes may occur in this fluid, which will be again alluded to when
these conditions are described.

The nervous system indicates in many ways not only its affection
by the general state of the system, but also by the special conditions
of indigestion. Languor and inaptitude for exertion, and a sense of
weariness in the limbs, which are most evident after meals, are often the
earliest, and sometimes during a long period the only, symptoms of the
disturbed functions of digestion. These sometimes pass into an almost
unconquerable drowsiness after food, which, when yielded to, affords
a heavy but unrefreshing sleep. There is frequently an impairment
of the intellectual faculties, which, though more marked during the
period of digestion, also continues at other times, and chiefly affects
the memory and attention, and the temper is apathetic and timid.

The duration of this condition is very indefinite, depending as it
does in a great measure on the persistence of the causes in which it
has its origin. If these be removed, and a healthier state of general
nutrition be restored, the stomach may, in some cases, easily regain its
tone and functions, but in other instances a marked diminution of the
digestive powers may persist long after the original cause of disturb-
ance has been removed.

Sometimes the combination of weakened nutrition and diminished
functional power conduces directly to further changes, excited by the
irritant action of the undigested food on the mucous membrane, and
giving rise to phenomena of a more or less inflammatory character.
These not only greatly aggravate the original symptoms, but tend
materially to prolong the duration of the disorder; the progress of
which is frequently varied by acute exacerbations attributable to this
cause, and which, it is important to remark, may also be brought into
operation by medicinal stimulants administered without sufficient
cautions.

Pathology.—The form of disorder of the digestion now under
consideration rarely depends on conditions by which the stomach
alone is affected. It is with so much greater frequency associated
with general states of the system characterised by the terms Atony
or Asthenia, that its pathology, in the majority of instances, only
forms a part of that of the constitutional states signified by these names,
which, if not in all cases capable of precise logical definition, have
nevertheless a tolerably distinct meaning. At present they are
generally understood to signify a simple impairment of the functional
powers of an organ or tissue unattended by appreciable anatomical
alterations. In relation to these, however, it requires also to be
stated, that as healthy function presupposes and absolutely requires

1 Sir J. Clark lays great stress on this diminution of the intellectual powers. "Climate,"
ed. 1839, p. 257.

2 See a remarkable case of this kind recorded by Andral, of dyspepsia originating in
for its performance a healthy condition of nutrition and innervation, so in most of the cases distinguished by simple diminution of power, unattended by other marked derangements of function, both the nutrition in a molecular sense and also the chemical constitution of the tissue are more or less impaired or perverted. In many instances, however, the nature of these finer alterations is at present unknown; and if in some cases the defect in the vital action is referred to disturbances in the innervation, we are only carried back a step further to an inquiry of the same character, concerning the condition of the nervous structures, and where the same as yet unsolved problem confronts us.

**Morbid Anatomy.**—Though in a certain number of cases of atony or asthenia the inference of mal-nutrition underlying this state is rather a matter of induction than of positive proof, there is yet a large class where it appears to depend directly on appreciable anatomical alterations of the nature of atrophy or degeneration, the vital phenomena exhibited by which are frequently clinically undistinguishable from those of the former order to which we have alluded. In this class may therefore be first mentioned those forms of simple atrophy of the mucous membrane of the stomach, associated with marked thinness and transparency of its walls, which have been mentioned by earlier, and even by some modern, writers, with very little reference to their clinical significance, but which, as has been shown by the researches of Dr. H. Jones, Dr. Habershon, Rokitanski, Dr. Fenwick, and the author, are often combined with fatty degeneration and wasting of its tubular structures. These have been found in many instances to have been replaced by a greater or less amount of fibro-nucleated tissue, and this change has been observed by Drs. Handfield Jones, Habershon, and the author, to be in many cases associated with distinct loss of power in the digestive functions during life; while Dr. Fenwick has proved that in such cases the digestive powers of the mucous membrane after death are also markedly diminished.

3 Pathologische Anatomie.
6 In a former paper of purely pathological investigation into this subject, before quoted, I stated that I had not then had the opportunity of tracing the clinical histories of the patients whose stomachs I had examined. Since that period I have, however, been able to trace in several instances the concurrence of anorexia and loss of digestive power with these conditions of degeneration.
7 In Dr. Fenwick's cases the stomachs so altered showed scarcely any traces of self-digestion, and the mucous membrane, after the addition of hydrochloric acid, when digested with 10 grains of albumen, dissolved only \(\frac{1}{10}\) of a grain, whereas 11 grains of albumen digested similarly with a healthy stomach lost 4 grains.
Both Drs. H. Jones and Fenwick have shown that these conditions may occur independently of inflammatory action. The author's researches have, however, convinced him that such degenerations are produced with great frequency in the stomach, as in other organs, through the destructive effects of this process upon its tissues, and that therefore in many instances simple atony may be regarded as the result of a pre-existent inflammation, though not necessarily indicating its continuance as a cause of the state—a proposition which affords pathological evidence and support to clinical observations on diseases of the stomach, where irritative action has often been known to be followed by long-continued asthenia.

In several of Dr. H. Jones's cases the changes in question were met with at advanced periods of life, and probably belong to the category of senile degenerations. Dr. Fenwick has also pointed out that in the cases in which he observed these alterations in the stomach analogous degenerations had occurred in other tissues, and especially in those of the vascular system.2

Closely allied to these conditions of degeneration are those where the digestive power is weakened and sometimes almost completely abolished by inflammatory or febrile conditions of the system, and of which Beaumont's observations on Alexis St. Martin gave such very distinct evidence.3 Histological investigation also reveals in the stomach changes similar to those discoverable under these circumstances in other glandular organs, as well as in the heart and voluntary muscles. The epithelial cells are granular and disintegrate easily, evincing a tendency to an unduly rapid retrograde metamorphosis, by which their functions are impaired or diminished. The condition is, indeed, one which it is not always easy to distinguish from the earlier or minor degrees of recent inflammatory change; but there can be very little doubt that molecular softening and granular disintegration may occur independently of this process. Tissues thus weakened in their nutrition are, however, liable to undergo, from the slightest causes, acuter destructive processes associated with vascular disturbance, to which the author believes that the name of "Inflammation" may still, in the present state of our knowledge, be applied; and therefore, while some of the forms of the so-called dyspepsia febrilis belong to simple atony from arrested nutrition, another and a very large class, to which allusion will be made hereafter, require to be classed under those having an inflammatory origin.4

1 See especially pp. 96, 107, 113, 126.
2 Dr. Fenwick's observations were chiefly made upon patients dying of cancerous disease of the breast. As catarrhal conditions of the stomach are very common in cancerous disease, even when this organ is not affected by the growth (see Lebert, Traité des Malad. Canc. 115), the degenerations found by this author may possibly have been the result of past inflammatory conditions.
3 See also Bernard's confirmation of this evidence, Arch. Gen. Suppl., 1846, pp. 8 and 294.
4 Beaumont's description is so graphic, and possesses the so infinitely great advantage of being drawn from life, instead of from more dubious post-mortem changes, that it
DISEASES OF THE STOMACH.

DIAGNOSIS.—The difficulty in the diagnosis of all forms of dyspepsia depends on the fact before alluded to, that the symptoms arising from imperfect changes in the food are common to all conditions in which these may originate. The discrimination of the form now under consideration depends mainly on the absence of the evidences of organic affection and of severe nervous derangement, coupled with the etiological circumstances of its origin. It is essentially a chronic affection, and therefore is mainly to be distinguished from chronic catarrhal inflammation. The chief features by which atonic dyspepsia is thus distinguished are.—(1) The minor degree of gastric uneasiness, and the absence of epigastric tenderness; (2) the simple deficiency of appetite, and the absence of thirst; (3) the absence of pyrexia; and (4) the condition of the tongue, which exhibits no signs of irritative action of the gastro-intestinal tract\(^1\) (see Chronic Catarrh, p. 869), but is pale, broad, and flabby. The constitutional symptoms are also less severe, and the course of the affection is more uniform.

The diagnosis from cases of ulcer and cancer is easily made when in these affections pain, vomiting, and hæmatemesis are present. In the earlier stages of cancer the diagnosis may, however, be extremely difficult, and sometimes it is impossible to obtain absolute certainty. The conditions which would attract suspicion of the more serious disease are failure of appetite, loss of strength; anaemia or other signs of cachexia occurring without manifest cause in a person who has passed the age of forty. Pain, when not traceable to intestinal colic, should always excite suspicion of a more serious disorder than simple functional dyspepsia.

The Prognosis of atonic dyspepsia varies with its ætiology. Cases where the disorder is of purely functional origin, and induced by causes acting directly on the stomach, are usually amenable to treatment. When, however, it is only a part of a more general condition, the restoration of the powers of the stomach must depend on the possibility of improving the health of the patient, and of removing the conditions which have induced the disease.

Cases also where there is any suspicion of degenerative changes in the glands, as in obstructive senile dyspepsia, or where symptoms of indigestion persist after long-continued evidences of inflammatory or catarrhal conditions of the mucous membrane, have necessarily appears well that it should be again quoted in extenso, especially as it affords convincing proof that the two distinct conditions of the stomach may exist under these circumstances; the one irritative, the other atonic:—

"In febrile diathesis, or predisposition from whatever cause, . . . the villous coat becomes sometimes red and dry, at other times pale and moist, and loses its smooth and healthy appearance; the secretions become vitiated, greatly diminished, or entirely suppressed; the mucous coat scarcely perceptible, the follicles flat and flaccid, with secretions insufficient to protect the vascular and nervous papillæ from irritation."—Loc. cit. p. 98.

\(^1\) For a further discussion of the value of these indications the author would again refer to a previous work, "Diagnosis and Treatment of Dyspepsia," p. 16 et seq.
much more unfavourable aspects than those where the state is one of mere functional inactivity.

When connected with or arising from anaemia, the result of organic disease in other organs, atonic dyspepsia, though seldom immediately fatal, not unfrequently proves a most serious complication of the original disorder, tending further, with a rapidity proportioned to its severity, to impair the strength and the general nutrition of the patient. When uncomplicated it rarely appears to act directly as a cause of secondary diseases, but it seldom continues long without passing into some of the irritative forms, and the effect of these is not only to maintain, but also to aggravate, the original condition. The injury therefore which it causes to the general nutrition may predispose to the disease of other organs, as the lungs, brain, heart, or kidneys, according to the several liabilities of each of these as a locus minoris resistentiae to other injurious influences which may come into operation; but I confess that I am indisposed to entertain the opinion that simple functional impairment of the powers of the stomach has any tendency directly to induce the more serious organic diseases of this viscus, such as ulcer and cancer.1

The treatment of this form of dyspepsia is comprehended under the title of Tonic, and implies the use of all such agencies as are capable of increasing functional power by restoring the conditions of healthy nutrition; indications which are to be fulfilled by measures adapted—

1. To improve the quality of the blood, and to regulate its transmission, by means of suitable diet, by medicinal agents capable of altering its composition, when this is defective, and by re-establishing the digestive and nervous powers.

2. To enable the system to appropriate and act upon the nutriment conveyed to the tissues, through methods calculated to favour healthy metamorphosis and the elimination of effete products. Our object is thus simultaneously to increase the vigour of the system and also of the stomach; since it must be remembered that, while the due performance of the functions of the latter is essential to the nutrition of the body, yet, on the other hand, a permanent increase in the powers of any single part cannot take place without a healthy condition of the whole system.

The treatment directed to these objects may be conveniently divided into regiminal and dietetic, and medicinal.

(a) Regiminal and dietetic.

As regards diet, the primary necessity is to administer the most easily assimilable food, and at the same time to avoid overloading the stomach, and thus aggravating the existing weakness, or giving rise to inflammatory irritation.

In cases of great impairment of the digestive powers arising from pyrexial conditions, haemorrhages, long privation, or exhausting dis-

---

1 This opinion has been expressed by M. Beau.
DISEASES OF THE STOMACH.

charges, food must be given in very small quantities at short intervals. Milk, and strong beef-tea, and animal jellies, combined with alcoholic stimulants, are the forms that should be selected for this purpose.\(^1\)

For the less severe but more frequent forms that are met with in the dyspepsias of the sedentary, or of those subjected to mental strain or anxiety, the main outlines of diet only can be sketched in this place. Three moderate meals daily are usually sufficient, but a fourth may occasionally be permitted on retiring to rest. A cup of tea may, however, often be taken with advantage before rising in the morning. The food chosen should be varied, but selected for its digestibility.

Fresh-cooked meat should be eaten at least twice daily. Beef and mutton, and game, with the exception of hares and rabbits, are to be preferred. Chicken, calves' feet, sweetbread, and tripe may also be permitted; but pork and veal, and salted or preserved meats, should be excluded. Eggs, when they agree, are to be recommended.

Fish is less desirable, but may be eaten with moderation. Oysters often are found to agree well; but differences in this respect are observed in individual cases.

Vegetables should by no means be excluded; but caution is requisite in their use. When they cause much flatulence, their place may be supplied by rice or macaroni, and by some fruits, especially by grapes, strawberries, and stewed prunes. Potatoes should always be well boiled, and not eaten too young. Other vegetables should also be fresh and carefully boiled. Turnips, parsnips, Jerusalem artichokes, onions, and the cruciferae often disagree; but spinach, vegetable marrow, beetroot, young peas, and French beans may commonly be taken in moderation.

Bread should not be eaten new. Aërated bread often agrees better than the ordinary forms. Biscuits or toast are often, however, preferable. Fresh butter may also be eaten in moderation.

Pastry is to be eschewed; but light farinaceous puddings generally agree well. Fried dishes should be forbidden, and in the same category must be placed the crustacea, nuts, pickles, and cheese.

Much fluid at meals should be avoided. Cocoa made from the nibs, or milk and water, may be taken when tea and coffee disagree. A moderate quantity of wine should however be taken twice daily.\(^2\) The selection may commonly be left to the patient, unless under special circumstances. Sherry, claret, hock, and champagne generally suit the best. Malt liquors are only to be used with caution, as they often cause flatulence.

Sugar\(^3\) may be used in moderation; but other condiments are to be avoided, except in the case of elderly people, or of those habituated

---

1 The methods recently proposed by Dr. Marcet ("On a New Method of preparing Meat for Weak Stomachs") and by Dr. Pavy (loc. cit.), of subjecting animal food to artificial digestion before its administration, may prove to be beneficial in these cases.

2 Bernard, Lec. Phys. Exp. ii. 420, has shown that diluted alcohol is one of the most effective stimulants to the secretion of the gastric juice.

3 Independently of its value as an article of diet, sugar has been shown to be an effective stimulant of the secretion of the gastric juice (Blondlot, p. 223).
to their use, since they have been shown to possess very little power of increasing the amount of gastric juice, and are liable to cause irritation.

The general regimen must also be tonic, including under this head sufficient rest ¹ both at night and also after meals; the avoidance of hot, ill-ventilated apartments, both in the day and at night; and the spending as much time as possible, consistently with the avoidance of undue fatigue, in the open air. Travelling, especially in open carriages, yachting, or sea-voyages, frequently prove highly beneficial in cases marked by much weakness, while for those of less severity horse exercise is as a rule more advantageous than walking. Exercise, especially in the open air, pushed to a degree short of producing exhaustion, has probably a greater influence in increasing the digestive powers of the stomach than any other single measure; hence for those who of necessity lead sedentary lives in large cities the use of gymnastics often proves of great service, by bringing into play a larger proportion of the muscular system than is exerted in mere walking. It must, however, be remembered that exhaustion is to be most carefully avoided, and that after any active exercise a sufficient amount of time should be allowed to elapse to allow the body to cool and the nervous system to repose before food is taken. ²

The influence of the intellectual and moral functions on the digestive powers is so marked that it cannot escape notice in this place; and it should always be recommended to patients harassed by care or anxiety, as well as to those engaged in absorbing intellectual pursuits, to take their meals in cheerful society. In many such cases, however, a complete cure is unattainable, except by a change of thought and scene.

The effects of cold bathing will, as a rule, be beneficial or not according to the powers of reaction of the patient. It is decidedly injurious when this is not speedy and complete and lasting, and even in some of the latter class the exhaustion following the bath more than compensates for the temporary pleasure derived from its use. A healthy state of the skin being, however, a great object, a tepid bath taken daily, together with the use of the hair-glove or flesh-brush, should be strongly recommended. A residence even temporarily in a dry and bracing climate is frequently of the highest value. The air of Brighton often proves of great service when there is no irritability of the mucous membrane; and next in order may be placed Scarborough, Dover, Folkestone, Margate, Eastbourne, Malvern, Tunbridge Wells, and the Surrey Downs; Ilfracombe, on the western coast, also possesses many advantages. A high situation, on a porous soil, is that which in general is best suited to patients of this class.

As a prelude to all discussion of the effects of medicinal treatment

¹ The importance of perfect rest is shown by a case of Andral's (Clin. Méd. ii. 191), when a condition of atony supervening upon irritative dyspepsia was only finally cured by retaining the patient for more than two months in bed.

² If exhaustion is felt after exercise, it is often advantageous to take a small quantity of an alcoholic stimulant a short time before the food.
DISEASES OF THE STOMACH.

for this disorder, it is not unimportant to state that, although often proving of great value as adjuvants of the general hygienic measures which have now been indicated, the employment of drugs independently of these is of comparatively little service. Even under any circumstances, no little caution is necessary in the selection, doses, and mode of administration of medicinal agents, in order to avoid the causation under their influence of irritative conditions, which are peculiarly liable to supervene in tissues whose vitality and power of resisting external impressions is already below the healthy standard.

The objects to be fulfilled by therapeutic measures may be conveniently summarised under the following heads:—

(1) Tonics to permanently increase the powers of the organ and of the system generally.

(2) Stimulants or stomachics to increase the secretory powers of the stomach, and which, by thus accelerating the digestive process, act indirectly as tonics, by favouring the assimilation of nutritive materials.

(3) Adjuvants to supply materials in which the gastric juice may be presumed to be sufficient.

(4) Certain remedies for special symptoms or conditions, which may not only hinder the digestive process, but interfere with the comfort of the patient.

When anaemia is present, the use of iron is strongly indicated; but its action is less marked in cases of functional debility unattended with this state. The carbonate, the potassio-tartrate, the ammonio-citrate, or the ferrum redactum usually suit the best; but when there is much relaxation of the tissues the tincture of the perchloride or the sulphate may be used. The former may be given before meals, the two latter should be taken immediately after food. If these preparations disagree, the lactate or the syrup of the pyrophosphate may be sometimes resorted to with advantage. Parish’s acid syrup of iron and lime often agrees well with children, to whom also the vinum ferri is well suited. When constipation is a marked symptom, and also in females whose menstruation is scanty or infrequent, iron may often be combined with advantage with one or two grains of the watery extract of aloes.

In other instances the natural mineral waters of Tunbridge Wells, of Spa in Belgium, or of Homberg, Kissingen, or Schwalbach, prove of greater efficiency than any pharmaceutical preparations, though it is probable that a part of the benefit in these cases is attributable to the adaptation of the climate of these places to the wants of the system, as well as to the advantages resulting from change of scene and of the mode of living, which those experience who visit these places from distant parts.

It should be mentioned as a caution, that in conditions of gastric irritability iron is usually tolerated with difficulty; and that some preliminary treatment is often necessary before, even in atonic dyspepsia, its administration can be pursued with advantage. It may often

vol. ii.
be advantageously combined with mild aperients, of which the aloetic class are generally the best, and particularly in the case of chlorotic females.

Much caution is requisite in resorting to the vegetable bitters, many of which, though increasing the appetite, appear to have little or no influence in augmenting the digestive powers, and further, have frequently a considerable tendency to cause irritation of the stomach. Their effect also as tonics, in any general sense of the term, appears also to be of a very questionable nature.

Two remedies of this class have, however, a more distinct general, and a more persistent local effect, and therefore appear to deserve a place among the tonics, viz. nux vomica, or its alkaloid strychnia, and quinine. The former of these often proves a most valuable tonic remedy, improving apparently the nervous energy of the stomach, as well as that of the system at large. Thus in many cases, by increasing the muscular contractility of the stomach and intestines, it aids (in addition to the antiseptic effects common to all bitters, but largely possessed by strychnia) in preventing the distension by flatus, which is so common and distressing a symptom in the cases now under consideration.

The most convenient mode of administering it is in the form of the tincture, in doses of from five to ten drops, with infusion of orange-peel and syrup; and it may be advantageously combined with the mineral acids, in cases which appear to require the administration of these remedies. Its use in many of the painful neuroses will be further alluded to when they are treated of.

Quinine is a more doubtful remedy in stomach affections, though at times it undoubtedly does good service. Its tendency to cause headache, and also nausea and irritation of the stomach, require caution where any signs of the latter condition exist. Still, in cases of convalescence from severe diseases, when the tongue is clean, but pale, broad, and flabby, and there is little tendency to constipation or to congestive headache, and also in persons of lymphatic constitution with relaxed conditions of the system, it often proves of value. It may be given in pill or powder, in doses of one or two grains, taken daily before or with meals, or in the form of the Tinct. Cinchonæ Composita, or Battley’s Liquor Cinchome, both of which preparations often appear to agree better than the pure alkaloid. In other cases, where iron is simultaneously indicated, the Ferri et Quinæ Citras may be resorted to.  

1 See on this subject Buchheim’s “Arzeneimittellehre,” p. 42; Shrenk, “De Vi et Effectu quorundam Medicaminum in Digestionem;” Diss. Inaug. Dorpat. 1849; Clarus, “Arzeneimittellehre,” p. 1014. These authors have remarked that the increase of the appetite is only due to local irritation—an effect which, as Griesinger, Arch. Phys. Heilk. vi. 399, has shown, results equally from small doses of many of the more irritant metallic poisons.

2 Quinine more frequently disagrees when given in solution in conjunction with sulphuric acid: a combination rarely indicated, but which, as it appears to me, is too frequently employed.
The other remedies of the class of bitters appear to rank rather among the stimulants and stomachics than with the tonics as above described. They may therefore be conveniently subdivided into four sub-classes, viz. simple bitters, aromatic bitters, aromatics, and stimulants to the gastric secretion of a more general character.

The simple and aromatic bitters have the greatest influence in increasing the appetite, and when this is defective their administration is especially indicated, but with the caution that loss of appetite is not always to be relied on as a diagnostic symptom of atonic dyspepsia, but is common in many inflammatory diseases of the stomach, when the use of these remedies is prejudicial. The effects of many of these are familiar enough to the profession, and also to the public, especially in the use of infusion of quassia before meals; and chiretta appears to have a very similar action.2

Judging from the researches of Corvisart, it would appear that the aromatic bitters, in addition to their powers of increasing appetite, have a greater influence in promoting gastric secretion than those last-named, and among the principal remedies of this nature may be enumerated absinthe, hop, chamomile, cascara, and calumba.

Of these calumba holds the chief place in point of therapeutic value, as a remedy which can be safely employed when others of the class would be too irritating.3 It may be used as an infusion or tincture, and the former may often be advantageously administered in conjunction with other aromatics, or with acids, alkalies, or ferruginous preparations; but when a more active effect of the same character is required, other remedies of this class may be resorted to with benefit.

As regards the more direct stimulants, their administration is indicated before or with food. The effects of a moderate quantity of wine in aiding a weak digestion have been already alluded to; and bitter

---

1 It is important in relation to this subject that the varied effects of different agents on the gastric secretions should be constantly remembered. Blondlot (Traité Analytique), Bernard (Arch. Gen. 1846), Corvisart (Longet's Physiologie, 1861, p. 184), have shown that the most active agents of this nature are alkalies (and in this respect the effects of the alkaline saliva must be remembered), cold water, diluted alcohol, ether, sugar, absinthe, chicory, ipecacuanha, nitrate of bismuth, and diluted solutions of common salt. Stronger stimulants, such as cathartics (Blondlot, loc. cit. p. 213, Beaumont, loc. cit. p. 182), powdered salt (Bardeleben and Frerichs, loc. cit. art. "Verdunung," p. 788), condiments (Beaumont and Buchheim and Engel), and even mechanical irritants, as charcoal (Corvisart), produce a large amount of mucous secretion, either alkaline or feebly acid, but possessing but small digestive powers. To these Corvisart adds black coffee, the effects of which must appear, however, somewhat doubtful to those who are acquainted with the almost total arrest of digestion which sometimes follows its use. Its effect, however, appears to be of an opposite character in different classes of patients, suiting well the lymphatic temperament, but injurious to persons of nervous excitability. See Troussseau et Pidoux, Traité de Thérap. ii. 593.

2 Of gentian it should be observed, that though possessing the advantages of a laxative in addition to those of a bitter, its characters as an irritant are more marked, and that additional caution is therefore requisite in its use.

3 Calumba appears to possess some direct "sedative" properties; thus it is sometimes useful in the vomiting of pregnancy and in sea-sickness, and even in minor degrees of subacute inflammatory action, and has been known to check the vomiting caused by tartar emetic (Pereira).
beer, combining the aromatic and bitter qualities of the hop, often proves of service in milder cases, where flatulence is not one of the symptoms complained of. Where, however, there is a tendency to fermentation of the food, malt liquors are distinctly contra-indicated.

Another remedy of the same class, ipecacuanha, originally prescribed by Daubenton, has of late been brought into more common use, by the advocacy of Dr. Budd. It should be given in pills, in doses of half a grain to one grain before meals, and may often be combined with advantage with three or four grains of rhubarb.

Other combinations of the same kind occasionally prove useful, such as chamomile\(^{1}\) together with rhubarb and ginger. Cayenne pepper is sometimes employed in the same manner, but its use is less advisable. The value of alkalis when taken with meals, in the form of Vichy water, liquor potasse, or the carbonates of potash and soda in combination with wine or malt liquors, is probably in some degree attributable to their physiological effects on the secretions of the gastric juice. They have also been employed for the same object by my friend and colleague, Dr. Harley, in small doses, properly diluted, before meals, with good effects in promoting digestion.\(^{2}\)

As *adjuvants* to the process of digestion, two series of agents deserve especial mention, viz. the mineral acids and pepsine.

The efficacy of the former of these has been long known; nor is their use limited to cases of simple atony, but they sometimes prove serviceable in many cases of irritative dyspepsia when from inflammatory causes the secretion of gastric juice is defective, and to which fuller reference will hereafter be made.

Of these acids the hydrochloric stands undoubtedly the first in point of utility, a fact which is easily comprehensible from its being probably the most active agent in the normal process of digestion. It should be taken, in doses of from fifteen to twenty drops of the dilute acid of the British Pharmacopoeia, suitably diluted with water, immediately before, or during, or directly after a meal. It may be rendered more palatable by the addition of syrupus aurantii; and may often be very advantageously combined with some of the bitter remedies before mentioned, especially with the tincture of nux vomica, the liquor cinchonae, or the infusion of calumba. Employed in this manner it will often, in the less severe cases, be found to relieve the sense of weight and distension ensuing after food, and it frequently prevents the acidity and flatulence arising from the fermentation which results from the imperfect action of the gastric juice; though it may be considered problematical whether in these doses it has any

---

1 Chamomile has the advantage of possessing slightly laxative properties, and is said by Trousseau (Traité de Thérap.) to be very beneficial in the atonic and flatulent forms of gouty dyspepsia.

2 The effect, as Blondlot and Bernard have shown, of the administration of a small amount of diluted alkali on an empty stomach is to cause a secretion of gastric juice, much greater than is sufficient to neutralize the alkali.
intrinsic power of checking this process which Liebig\(^1\) asserts the stronger mineral acids to possess, and to which Pemberton\(^2\) attributed their influence in this direction.

The phosphoric and nitric acids have been recommended for the same purposes by other writers (Todd, Pemberton), but their influence in aiding digestion is much less marked than that of the hydrochloric, while nitric acid not unfrequently produces irritating effects on the stomach, and may give rise to pain or nausea.

Dr. Handfield Jones\(^3\) has for similar purposes found the use of lactic acid, as recommended by Magendie,\(^4\) to be productive of good results: he administers it in doses of fifteen to twenty drops, suitably diluted, at meal times, and, in some cases of irritative dyspepsia, considers it decidedly preferable to the hydrochloric.\(^5\)

Though the efficacy of pepsine has occasionally been called in question by some recent writers, my own experience would induce me to bear a strong testimony in its favour—not only in the form of dyspepsia now under consideration, but also in some conditions when the digestive process is impaired by irritative states of the mucus membrane. It may often be very advantageously taken simultaneously with hydrochloric acid at meal times.

The complications of this state which most call for medicinal relief are Constipation, Flatulence, and Acidity.

In remedying constipation, much care is required to avoid irritation, and only the gentlest and least irritating laxatives are desirable. When possible, even these should be dispensed with, and the action of the bowels, when not occurring spontaneously, should be daily solicited by the use of enemata of cold water.

Friction, or the wet compress worn at night, protected by a piece of mackintosh, or the use of the cold douche to the abdomen, are often useful adjuvants in this respect.

When medicines are used, rhubarb and aloe are to be preferred to all others. Either may be given with food, a method which diminishes to some degree the danger of irritation resulting from their use, and they frequently may, with advantage, be combined with small doses, as a quarter of a grain, of the extract of nux vomica.

Recourse should however be had as little as possible to purgative remedies, for it may become difficult afterwards to shake off the habit of requiring their aid, and the use of strong aperients tends still further to exhaust the muscular and nervous powers of the intestines.

4 Formulaire pour la Préparation et l'Emploi de plusieurs nouveaux Médicaments. 1835.  
5 Hünefeld's experiments under Budge, "De Albuminis Suco Gastrico faecitio Solubilitate," showed that hydrochloric acid gave the greatest digestive powers, lactic acid less, and acetic acid the least (Canstatt, 1859, i. 30). Trouseau's clinical experience of the relative value of the mineral acids indicates a decided superiority on the part of hydrochloric (Clin. Méd. ii. 377). Meissner also has found that in artificial digestion, it is necessary to use ten times more lactic than hydrochloric acid to produce a digestive mixture of the same strength (Hänle and Pfeuffer's Zeitsch. 3d Ser. vol. vii. p. 10).
In many cases of atonic dyspepsia, when there is any marked degree of weakness, there is very little occasion for a daily action from the bowels, though care to prevent marked degrees of constipation occurring should always be exercised.

When acidity and flatulent spasm exist together with the constipation, antacids, and especially the magnesia usta, or magnesia carbonas, in combination with tinct. rhei and aromatics, may be employed with advantage for the same objects. In severer cases, especially in the gouty flatulence of elderly people or of females at the climacteric period, assafcetida, either in combination with aloes or in the form of the compound galbanum pill, is frequently of considerable service. If the flatus exists in the stomach, large draughts of warm water may sometimes prove efficacious in promoting its expulsion by eructation;—while tympanitic distension of the bowels may be relieved by enemata containing turpentine, assafcetida, oleum rutae, or sometimes by infusion of chamomile.

Other remedies for flatulence may at times be employed, though they only act as very temporary palliatives, such as the more cordial aromatics, the spiritus ammonis aromaticus, the aqua anethi, or peppermint water. In some cases the absorbent powers of charcoal are of service, though to possess any efficacy of this kind it is necessary that it should be recently prepared.1

It must be remarked that no single plan of medicinal treatment should be too continuously protracted, and that a change of remedies within the limits of those above indicated is often productive of good effects. Many that seem at first beneficial appear after a time to lose their efficacy, and may be advantageously replaced by others of a different class according to the predominance of individual symptoms, and even the ferruginous preparation, on which so much stress has been laid, should not be persisted in without intermission.2

The period during which bitter remedies prove efficacious is equally limited. Preparations of nux vomica or calumba are tolerated longer than most of the others, but the prolonged administration of the former may entail nervous accidents and dangers of over-excitability of the spinal cord, which may sometimes persist to an unsafe degree after the discontinuance of the drug; and even when its use is beneficial it should seldom be persisted in longer than a month or six weeks. If the favourable effects of bitter remedies do not become apparent after a few days it is better to discontinue them, and under all circumstances to watch very closely for signs of gastric irritation, which, if present, they seldom fail to aggravate.

1 Belloc, who first introduced it, recommended that it should be made from the young shoots of the poplar, and stated that given in doses of from 30 grains to 3 drachms in the twenty-four hours, it acted slightly as a laxative. Dr. Leared has of late praised the efficacy of the charcoal made from vegetable ivory for this purpose.

2 Sydenham (Op. Omnia, Syd. Soc. Ed. p. 347) recommended their employment in hysterical or ataxic cases for a period of thirty days, and it is seldom that they can be taken with advantage for a longer period, though they may be resumed after an interval of ten days or a fortnight.
III. — NEUROSES OF THE STOMACH.

SYN. — Eretatism of Stomach (Barras and Trousseau), Gastralgia (Barras, Valleix), Morbid Sensibility of Stomach? (Whytt, Johnson).

DEFINITION.—An unnatural excitability of the stomach characterised by extreme degrees of perversion of its functions, or by an excessive exaltation of its sensibility; the principal symptoms of which consist of either pain, vomiting, perversions of its secretions, and commonly of the appetite, which are frequently, but not constantly associated with an impairment of the digestive powers; but are unattended by any appreciable anatomical change, and which usually occur under conditions capable of producing reflex irritation, or of inducing asthenic constitutional states associated with extreme nervous excitability.

The immediate mechanism of the production of such conditions appears thus to depend in some cases on nervous disturbance, which may be designed as primary, while in other instances they originate from the disorders of other, and sometimes of distant parts, by which the functions of the stomach are affected in the manner just described as reflex.

ÆTIOLOGY.—The predisposing causes of disturbances of the functions of the stomach resulting from perverted innervation, while embracing many of those general conditions, which have been before enumerated as capable of inducing the atonic state, further includes the special causes which are capable, in addition to weakness, of giving rise to extreme nervous excitability. We thus find that they are predominant in the female sex,¹ and occur with much less frequency among men. They are, however, rare before puberty,² and they are less common at advanced periods of life, than between the ages of fifteen and forty. A special proclivity at two different ages is, however, in the female sex determined by sexual

¹ Georget, art. "Gastralgie," Dict. de Méd. x. 81, says that these nervous disorders are ten times more frequent in the female than in the male sex.
² With the exception of cases of vomiting from cerebral disease, and the rarer instances of simple uncomplicated, reflex disturbance of the stomach arising during dentition, the periods of infancy and childhood are comparatively free from the severer forms of gastric disorder of a nervous character. The immunity thus enjoyed in the earlier ages of life is probably, in part at least, due to the absence of those profounder impressions made by moral emotions, which, as will be presently mentioned, serve in a great number of instances as their determining causes. Some cases are, however, recorded by Dr. Handfield Jones (Functional Nervous Disorders, pp. 412, et seq.), where neurotic abdominal pain was observed in boys before and at the period of puberty (see especially one by Dr. Martin, of Rochester, Brit. Med. Journ. July 16, 1859). In some, however, of these cases the pain appears to have been seated in the abdominal muscles rather than in the stomach.
conditions, the epochs of the appearance and cessation of the menstrual function being in them peculiarly liable to be marked by these disturbances; while in the male sex the only extraneous influences determined through age, are such as result from the increasing anxieties and severer intellectual efforts which are often called for between those of thirty and fifty.

Hereditary disposition is by some writers mentioned among their predisposing causes, and there seems no reason to doubt its occasional possible influence in this direction.

Of the special determining causes, exhaustion plays the most prominent part, and when combined with other depressing influences, and particularly with those of a moral character and operating through the nervous system, such as grief, fear, anxiety, or severe intellectual effort, it is an almost unfailling source of perversion of the functions of the stomach, which can only be referred to disturbed innervation. These, however, may originate under almost any circumstances of impaired vitality or of diminished constitutional power, whether apparently spontaneous, as in the states of anæmia and chlorosis (which though most common in the female sex have been observed to be thus associated in men) or which may be produced by haemorrhage, or by privation of food, by venereal excesses, and particularly by the habit of masturbation.

Diseased states of the nervous centres may also act as causes of these perversions. The chief facts which are known with respect to these relations have been already alluded to, and they do not thus far appear to require further description in this place.

By far the most frequent, however, of all the causes assignable as the starting-point of these disturbances, are the complex states expressed under the terms Hystéria and Hypochondriasis. Their frequency

1 Thus, Whytt (Works, p. 568) mentions a case of a young man who was bled largely for a pain in the side, arising from a fall from a horse. After some days he was attacked by a sense of intense cold in the stomach, and this was followed by intense pain recurring in a paroxysmal form two or three times in the twenty-four hours. The attacks continued for some weeks, but he gradually recovered under the use of "stomachics;" but having on another occasion experienced a similar, though smaller, loss of blood, the attacks of pain returned, but in a less severe degree. See also a case where pain and acid vomiting occurred after attacks of haemorrhage from piles (Budd, p. 198). Haemorrhoids in hysterical women are capable of producing extreme reflex disturbance of the stomach. In a case lately under my observation these ceased after the removal of the immediate exciting cause.

3 Both gastric pain and vomiting may be excited by cerebral haemorrhage, so as even to give rise to suspicions of poisoning. A case of this kind came within the author's own experience (recorded in Bennett's Clin. Med. 1865, p. 405). A similar one is quoted by Henoch from Krukenberg. Unterleibs-Krank. ii. 205.

4 The frequency with which the perversions of the moral and intellectual functions which are included under this title are found associated with all forms of dyspepsia, may very properly give rise to the question, how far in all cases it can be regarded as standing
DISEASES OF THE STOMACH.

in hysteria may be estimated by the statement of Briquet, that of 358 cases of this affection, only 30 had no sign of "gastralgia," or "epigastralgia," 130 had only pain at the epigastric region, while 187 had both pain and derangements of the digestive function; and this author states that the latter are among the first symptoms in females in whom hysteria is slowly developed.

Among other causes operating probably on the general or local nervous centres through changes in the composition of blood, may be mentioned malarial conditions, which may impart to neuroses of the stomach a specifically intermitting character. From the present state of our knowledge of the pathology of gout, it would almost follow that this affection should be placed in the same category, though the dyspeptic disturbances occurring in patients of this class may be referable to widely different causes, among which inflammatory conditions probably play no inconsiderable part.

With them also may be included, but with a certain degree of reservation, the effects of long-continued alcoholic poisoning, which, as Dr. Budd remarks, greatly resemble those produced by exhaustion.

Of the immediate exciting causes, sudden emotions, especially of a depressing kind, are among those most frequently cited as having given rise to these disorders; but a similar effect may be produced by moral affections of the same character acting through a longer period.

The influence exerted by painful emotions not only in arresting digestion, but in producing painful sensations in the epigastric region, is well known, and these effects are greatly heightened in the case of patients whose nervous susceptibility is more than usually prominent.

As special conditions, acting locally, may be mentioned the abuse of stimulants and condiments, and in particular the habit of taking large quantities of tea and coffee.

Finally, in some cases the effects of idiosyncrasy must be considered.

to them in the relation of a cause, or whether in an almost equal number it is not either a direct consequence of the derangements of the digestion, or whether both these and the hypochondriasis are not together the expressions of a more general nervous disorder. There is, however, little doubt that, in whatever manner originating, the peculiar mental state accompanying this condition serves in no small measure to intensify the gastric disturbance already existing, through the exclusive direction of the mind to the sensations experienced in the stomach, the influence of which, as pointed out by Dr. Carpenter, in describing the effects of "expectant attention" on the organic functions, is by no means inconsiderable.

1 Traité de l'Hystérie, 251.

2 Niemeyer, loc. cit. p. 546.

3 This is hardly, however, to be spoken of as a simple state, inasmuch as these cases are usually complicated by catarrh of the stomach, attributable, probably, to the immediate effects of the alcohol on the mucous membrane.

4 See cases by Barras, Briquet, Andral.

5 The latter agent is very commonly admitted to be an exceedingly frequent cause of gastrodynia, and of dyspepsia associated with much nervous disturbance. See Clarus, "Arzeneimittellehre," p. 666; also Wood, "Therapeutics and Pharmacology," i. 628.

I have seen it stated, though I cannot find the original, that girls employed in needle-work, and in the Manchester factories, have not unfrequently a habit of chewing tea, with results evidencing a greatly disturbed condition of innervation both of the general system and of the stomach. The habit does not, however, appear common in London.
Some of these have been already alluded to, and reference may be made to two cases by Andral,\(^1\) in one of which the use of milk always caused violent pain, while in another honey invariably gave rise to vomiting.

The causes capable of acting on the stomach by reflex irritation, conducted from other parts, have also been dwelt upon in previous sections, and it is only necessary therefore briefly to recapitulate them in this place.

They are, as has been seen, very numerous, and include sympathies with parts whose apparent connexion with the stomach is very obscure, and some of which can only act, in all probability, through the general influence which pain exerts both on the appetite and on the digestive functions. Such are diseases of the external ear and of the teeth;\(^2\) painful affections of the kidneys, testicles, and ovaries; disordered conditions of the lower portions of the alimentary canal, among which must be mentioned piles, worms, constipation, hernia, including the omental and epiploic; diseases of the pancreas\(^3\) and of the liver, and especially gall-stones and abscess of the latter organ; and with a frequency far exceeding that of all those just enumerated must be mentioned diseases of the uterus, including tumours, polypi, ulcerations, prolapsus, retro- and anteversions, and yet more commonly disturbances of menstruation, leucorrhœa, and the state of pregnancy. With the exception of the last-named state—which is, however, far more frequently associated with disorders of the stomach in weakly than in strong and healthy patients—there are few of the uterine derangements here enumerated which are not more or less associated with an impairment of the general nutrition. The majority also appear to be more truly connected either as cause or effect with the primary disorder, than to arise through the disordered digestion, which is frequently the last in the series; while, with respect to frequency, though not perhaps to severity, leucorrhœa and disordered menstruation hold the foremost rank among this class of ætiological conditions.

**Symptoms.**—The class of symptoms by which nervous affections of the stomach are especially characterised have been already alluded to as consisting chiefly of pain, vomiting, and certain forms of hypersecretion. These may, however, occur in every possible variety of combination with each other, and with other symptoms of indigestion, as well as in very varying degrees of severity. No special relationship can, as a rule, be traced between any of them and the different ætiological circumstances just described under which they may occur; and causes apparently identical may, in different subjects, give rise to dissimilar symptoms; while, on the other hand, the most diverse per-

3 Claessen, quoted by Bamberger.
versions of function may occasionally be met with in cases whose mode of origin is to all appearance perfectly alike. Certain peculiar features do, however, mark some of the forms assumed by them, in connexion either with particular states of the system or with special causes of nervous irritation; and in the description about to follow, the disorders that occur in the course of hysteria, chlorosis, amenorrhea, hypochondriasis, exhaustion, gout, and certain uterine disturbances, will be more specially considered; those originating from other reflex conditions, or from organic diseases of the cerebral centres, being comparatively so rare and exceptional, that though their mode of causation is occasionally of diagnostic importance, they can hardly be included in a categorical description of the symptoms of the more usual forms.

The modes of invasion of these symptoms of nervous "erethism" may be either gradual or sudden, standing in this respect in an almost direct relationship to similar conditions in point of time or intensity of the exciting cause.

In the class of hysterical cases, loss or deprivation of appetite is sometimes an early symptom, proceeding in many cases either to an absolute anorexia, which may even involve the nutrition of the patient in considerable danger; or to some of the extraordinary perversions known under the names of Pica or Boulimia. Sometimes the last-named symptom becomes predominant, and the patients are affected with a ravenous and almost insatiable desire for food, compelling them to eat at all hours of the day and night, and the origin of which in perverted sensation is evidenced by the feelings of sickness, pain, and faintness which ensue if the gratification of this desire is withheld. "The psychical relations of the sense of hunger are altered; there is no appetite, and taking food affords no enjoyment." Severer symptoms, however, often speedily ensue, and among the most prominent of these are pain, which, however, varies greatly in duration and intensity.

Commencing ordinarily with a sense of constriction or oppression, or sometimes with a feeling of distension or weight, it is followed by sensations of an agonizing character, which are variously described by the patients as consisting of heat, cold, tearing, gnawing, rending, or twisting. In the severer attacks the heart's action is interfered with, becoming fluttering and irregular; the extremities are cold, and there is a tendency to syncope: in some cases convulsions are said to have

1 Briquet, p. 254.
2 Pica, Citta, Malakia Pseudorexia, signifies a perverted appetite, in which desires are experienced for unnatural kinds of food—coal, chalk, pins, or even loathsome substances. Boulimia is applied to an excessive desire for food. Copland's Dict. of Med. art. "Appetite." Landre, Beauvais, Dict. Sciences Méd. iii. art. "Boulimia."
3 This condition, though generally occurring in the female sex, may sometimes be met with in males, as is shown by an extremely marked case recorded by Chomel, Des Dyspepsies, p. 94.
4 Romberg, loc. cit. p. 107. Romberg remarks that this hyperesthesiæa rarely occurs in an isolated or idiopathic form, and that it is found in a variety of morbid states—sometimes appearing as reflex or sympathetic, sometimes associated with other hyperesthesias, and is observed during convalescence from severe diseases, in hysteria, helminthiasis, ergotism, or as the precursor of other diseases, and especially of gout.
ensued from the severity of the pain (Schmidtman). Pain of this
nature, though often aggravated by slight pressure upon the abdo-
mental muscles (épigastralgia of Bricquet) is usually relieved when
it is made more firmly and persistently, and this is especially true
of those forms that are associated with cramp or flatulence, but the
conditions observed in this respect are somewhat uncertain.

The pain is sometimes associated with distension of the abdomen,
at others this is sunk and retracted (Romberg). It is essentially
paroxysmal in its character, returning sometimes at irregular, in
others at regular periods on successive days in cases where the attacks
are not attributable to malarious influences. In other cases, it re-
turns only at the menstrual periods, and there is comparative im-
munity in the intervals.¹

The duration of the attacks is variable. They may last only for a
few minutes, or may continue for hours. They frequently terminate
in gaseous eructation, or with the ejection of a watery fluid, which
may be acid, or alkaline (pyrosis), or of mucous of an alkaline
character, and of variable degrees of tenacity; and they are commonly
followed by a sense of soreness at the epigastrum, and by great
exhaustion.

The relation of the effects of the ingestion of food to the pain is
subject to some variations. There is one distinct class, before alluded
to, where this gives distinct relief;² and these cases form not only the
larger number, but are those in which there is least suspicion of the
accuracy of the diagnosis. This effect is certainly that most commonly
met with in cases where the gastrodynia is associated with depressed
vitality arising from exhaustion, or with nervous irritability dependent
on moral or emotional causes. Another remarkable feature in these
cases is, that insipid food and demulcents often cause much more pain
than substances which are not only less digestible, but are even
irritating in their character; and this peculiarity, which has been
observed by numerous writers,³ is not without value in diagnosis.

In other and rarer instances, which especially occur in aggravated

¹ Barras gives two cases where gastrodynia was associated with suppression of the
menstrual blood in one of these the pain was less violent when the discharge became
more abundant. In this latter case there was also flatulence, and the pain was relieved by
food. (Loc. cit. i. 557.) Niemeyer, loc. cit. p. 545, also gives a case of this character where
the pain only occurred at the menstrual period, but in which the application of leeches
to the cervix uteri instantly caused its return. It must be remembered, however, that
an increase in the severity of the pain at the period of menstruation has been observed
in some cases of gastric ulcer.
² See Budd, loc. cit. pp. 282, 283.
³ "An uncommon delicacy of the nerves of the stomach, which may be either in a
great measure natural or brought on by disease, . . . excessive grief, or other causes,
is to be distinguished from that . . . increased sensibility, which is the consequence of
an inflammation, or of an aphthous state of those parts, since in these last cases every acid
substance gives them pain, whereas in the former many insipid and seemingly innocent
substances produce great uneasiness in the stomach and bowels, while volatile spirits,
strong wines, brandy, and spiceries, are not only inoffensive, but often necessary for
alleviating those disorders which are produced in the first passages by such causes as
would scarcely produce any disturbance in the second state." (Whytt, loc. cit. p. 544.
See also the same author, loc. cit. p. 566; see also Barras, loc. cit. i. 35, 414, 440.)
forms of hysteria, and in some where the pain in the stomach is of reflex origin, and more particularly where it is due to uterine disturbance, the ingestion of food is immediately followed by severe pain, which is only relieved by vomiting, and though in some cases the appetite may be preserved, the fear of the agony caused by the food entering the stomach prevents the patient from eating.\(^1\) In other instances, pain of this character is only felt some hours after food, but here the conditions are more complex, and pyrosis or great distension of the stomach from flatus are often present; in which latter case, though much of the pain felt may be due to the spasmodic contraction of its coats, some is also, in all probability, to be attributed to the cramp-like action of the abdominal muscles.

The state of the digestion sometimes affords a valuable criterion of the nervous origin of these affections; in many cases it is entirely unaffected in the intervals of the attacks,\(^2\) while in others the ordinary symptoms of atonic dyspepsia are present. The tongue is, as a rule, clean, though often pale, broad, and flabby;\(^3\) the bowels are generally confined, but the faeces are not otherwise altered. In cases, however, to be hereafter alluded to, when nervous excitability co-exists with various degrees of inflammatory irritation of the stomach, these signs are lost. One remarkable feature with regard to these attacks is, that where any predisposition to them is present they may be brought on by painful moral emotions.\(^4\)

Vomiting, though often attending the paroxysmal attacks last described, may also occur as an independent condition, unaccompanied by pain. This, though common in cases where it originates in reflex disturbances, or in certain disorders of the central nervous system, may also be observed in states characterised by simple perversion of function, and especially in hysteria. Its isolated appearance in the latter class, independently of other disturbances of sensation, is, however, the exception rather than the rule, though in some instances such pain belongs more to the class which Briquet has termed "epigastralgic," than truly referable to the stomach.\(^5\)

Nausea usually precedes to some degree the expulsive act; but its duration and intensity are shorter and less marked than in the vomiting which attends inflammatory or organic diseases of the stomach.\(^6\)

---

1 Briquet, p. 256. These cases are, however, those in which the accuracy of the diagnosis from ulcer must often be held in doubt, even when made by the most competent observer.

\(^2\) This can only be said to be relatively true in regard to the diagnosis of these affections from those of an inflammatory nature. The same fact is often observed in the progress of cancer, and sometimes of ulcer, when associated with epigastric pain.

\(^3\) The varieties of appearances of the tongue described by Dr. Todd, loc. cit. p. 632, as indicating this state, viz. "a thin white gauze," "a milky appearance," or "a covering of frothy mucus," belong, I believe, to catarrhal conditions.

\(^4\) Whytt, loc. cit. p. 560.

\(^5\) Sec a case related by Briquet, loc. cit. p. 218, of a girl who, after severe moral emotion, was brought to the hospital with violent pain at the epigastrum, together with vomiting, which excited the suspicion of poisoning. The pain was relieved in ten minutes by faradisation.
stomach—approximating in this respect to the conditions observed in the vomiting from cerebral causes.

In some cases intervals of several hours, or even days, may elapse between the recurrences of this symptom, and during them the digestion may be good, or there may be (as in pregnancy) some degree of acidity, apparently from hypersecretion, after each meal; but in others, and apparently in proportion to the severity of the exciting cause, and also in pregnancy and hysteria, the vomiting tends to become continuous. Under such circumstances the food is rejected either as soon as taken, or within a few hours after eating, being often returned completely undigested, and rarely associated with bile or mucus (Briquet). Even when vomiting is severe, the appetite may in some hysterical cases continue, and may even present an apparent increase of intensity, so that the patient’s time may be passed in alternate vomiting and eating; but in other instances, when the disorder has commenced after moral depression, and when pain is also present, there may be a more or less absolute anorexia.

In many cases of hysterical vomiting it has been a matter of repeated observation that the general nutrition and strength remain but little affected; but when the vomiting is severe and constant, emaciation may rapidly ensue from the loss of food thus occasioned. The occasional dangerous effects of this symptom in pregnancy are well known, and have been already alluded to, and others of a similar character are detailed by Andral and Budd, where, although vomiting had continued long, the stomach was found healthy after death. In some of the cases of the latter class, though fever was absent in their earlier periods (thus conforming to the rule generally observed), it appeared, associated with delirium, towards their close, and in some instances assumed a distinctly hectic character.

The effects of varieties of food in promoting or retarding the occurrence of vomiting, are almost as variable as are their relations to the symptom of pain. In the severer forms just alluded to, solids and meat have been known to increase both the pain and the vomiting (Budd); but when hysterical symptoms are well marked, indigestible and apparently unsuitable food may be tolerated when ordinary aliments are rejected as soon as taken.

There is another form of dyspepsia occurring under nervous influences, of which I have seen some examples, but which, as far as I

1 Briquet, loc. cit. p. 255.
2 Andral, loc. cit.
3 Clin. Méd. ii. 175—179.
4 Loc. cit. p. 261. With regard to Andral’s cases, however, the conclusions drawn from the apparently healthy state of the stomach should be received, in the author’s opinion, with some caution, on the grounds stated in the chapter on the post-mortem appearances presented by the stomach.
5 See a case by Barras, loc. cit. i. 496, where the first food retained was a salad made with hard-boiled eggs. A precisely similar one is recorded by Briquet, loc. cit. p. 307; another by Guipon, loc. cit. p. 349, when the acid vomiting of pregnancy was immediately arrested by the use of beer. 6 Vallez, Bull. Thérap. Oct. 1849, has noticed that meat and champagne were retained when milk was rejected, and that a kind of food which was retained in one day was vomited on the next, and vice versa.
DISEASES OF THE STOMACH.

am aware, has been fully described only by M. Trousseau.\(^1\) It occurs both in males and females, under conditions usually preceded by some cause of exhaustion, especially affecting the nervous system, and my friend and colleague Dr. Ringer informs me that he has also observed it in children. It is attended with an excessive appetite (boulimia), and by a sense of want following too speedily after food has been taken. The characteristic symptom is, however, that diarrhoea is present, and the evacuations, which are usually preceded by borborygmi and colicky pains, are induced with great facility by slight causes of an emotional character, and contain considerable quantities of food which have passed undigested through the intestinal canal. Frequently an evacuation occurs immediately on rising in the morning, and is followed by a great sense of exhaustion; and I have observed in some cases that this can be delayed until the usual hour after breakfast, by simply taking a small quantity of food before rising. Trousseau ascribes these symptoms to an undue irritability of the muscular coat of the stomach and intestines, hurrying the food taken too rapidly through the whole canal, without permitting time for its due elaboration, and the influence of appropriate treatment strongly corroborates his opinion.

The affections of the general system frequently associated with the conditions which have now been described are nearly all such as point to their relation to a common cause. Many of them belong to the category of neuralgias, which occur either in distant or in proximate parts, and their appearance often alternates with remissions in the gastric disturbances. These often affect the dorsal, thoracic, abdominal, and intercostal muscles; but they may assume the forms of toothache,\(^2\) hemicrania, lumbago,\(^3\) or sciatica.\(^4\) Instead of pain, other symptoms of nervous excitability may be present, such as attacks of cardiac palpitation,\(^5\) or of strong pulsations of the abdominal aorta,\(^6\) which often occur both during and in the intervals between the attacks of abdominal pain, and are distinguished by their sudden invasion and cessation, and by their rapid exacerbations. Dyspnoea,\(^7\) globus, hiccup, paralytic,\(^8\) syncopal,\(^9\) or convulsive affections, salivation, and

---

1 Clin. Médicale, ed. 1862, pp. 354, 365, 428, 429. This is probably also allied to the affection alluded to by Abercrombie, "Diseases of Stomach and Intestines," 3d edition, p. 71; and by Whytt, loc. cit. p. 530, as quick digestion.
2 Common in pregnancy.
4 Abercrombie, loc. cit. p. 86. Barras (f. 440) gives a case where a patient who had been subject to periodical headache became attacked with intermittent gastroduinia accompanied by the vomiting of mucus, but not of food, and which ceased on the supervision of scatica. Two or three such attacks, with a similar order of sequence, were repeated at considerable intervals.
5 This, however, is a symptom common to all forms of dyspepsia.
7 Whytt, loc. cit. p. 560.
8 A very interesting case of this nature, by Dr. Perceval, is to be found in the Med.-Chir. Trans. iv. p. 17.
9 Guipon, loc. cit. p. 118.
a copious discharge of pale urine\(^1\) have all been observed, with greater or less frequency as concomitants of these affections of the stomach, and indicate very clearly the condition of perverted innervation from which its Disorders arise, and which can be traced to the states of chlorosis, hysteria, melancholia,\(^2\) or hypochondriasis, in which they take their origin.

The sleep also is affected in the majority of cases, and particularly in hysterical patients, who not only experience a difficulty in going to sleep, but are liable to awake during the night, with a great sense of exhaustion and hunger. Insomnolence is also commonly observed in patients of both sexes in whom disorder of the stomach has been caused by anxiety or over-fatigue, though in them the feeling of hunger on waking is usually wanting. In other instances, however, of the latter class the sleep may be heavy, but it is often unrefreshing and disturbed by dreams.

Many of the disturbances of the functions of other organs of the body have been already spoken of in connexion with the description of special symptoms, and it is unnecessary again to repeat the remarks made on the subject of the appetite, the digestion, or the constipation and flatulence which, with some exceptions, mark these cases, nor on the irregular and scanty menstruation, or the leucorrhoea attendant on anaemia or chlorosis, whose influence has been already largely insisted upon. It has been observed that in many cases where hypochondriasis is most marked, oxaluria has been present; but as this symptom is common to a great number of diseases, and probably depends more or less directly either on an excess of animal food (Niemeyer)\(^3\) or on imperfect assimilation, its occurrence is rather to be associated with dyspeptic disturbances of another class, where the hypochondriasis, instead of being primary, is secondary to the disorder of the digestion, than with the more purely nervous disturbances now under considera-

One important class, to which Whytt first called attention, is that where severe disorder of the stomach occurs in connexion with the gouty diathesis, and ceases with the appearance of the disease in one of the joints.\(^4\) The attacks, however, as Whytt further remarked, are less liable to affect robust and strong individuals in whom the gouty affection is regularly developed, than in those of "weak fibres and very sensible nerves," who have "rarely any disorder like true gout," but who are liable to "craving or faintness, nausea or vomiting, flatulent swellings, borborygmi, low spirits, cramps, convulsive and violent pains in the stomach and bowels, and an increased secretion of saliva." In other cases severe spasmodic affections of the stomach occur in the course of gouty attacks, and are characterised by violent abdominal pain, intense distension from flatus, and severe sinking, followed in

---

\(^1\) For a case of this kind occurring in a male patient, see Whytt, loc. cit. p. 557.

\(^2\) See Marshall Hall, On the Mimoses.

\(^3\) Loc. cit. i. 554.

\(^4\) Works, pp. 556, 559.
some instances, when wine has been drunk, by acid vomiting, which has given relief.\(^1\) The nature of these disorders is, however a matter of some doubt; and though evidence regarding them is still wanting, there is considerable probability that many of them are not simple neuroses, but are rather to be classed under the category of acute indigestions, complicated by a predominance of nervous excitability together with prostration.

**Prognosis.**—The course of these affections is, as may be inferred from their history, very variable. Their duration depends in a large measure on the persistence of the exciting cause, ceasing with its cure, as is often observed in cases originating in anemia or chlorosis, or in those arising from reflected irritation, especially when the cause is seated in the uterus.\(^2\) The rapidity of their disappearance on the supervision of some other nervous phenomena affecting other parts, or of an attack of gout in cases when this diathesis is present, has already been a subject of remark.\(^3\) Barras has observed that in some cases they disappear on the supervision of acute diseases, as fevers,\(^4\) pneumonia, abscess, or variola, but are liable to reappear during or after convalescence.

The majority may continue for years with but little danger to life, and this is true not only of the minor degrees of hypochondriacal uneasiness, but even of some of the severer cases of hysterical pain and vomiting. The hysterical forms, like all the other phases of this malady, are liable to diminish in severity and even to disappear with advancing life.

Briquet\(^5\) remarks that the vomiting of hysteria, though sometimes very obstinate, is the least dangerous of these affections. That it may, however, be attended with fatal consequences, and especially when constantly ensuing after everything eaten, and when associated with severe pain, is evident not only from his, but also from observations recorded by Andral, and Barras, and Budd. The danger resulting to the general nutrition from the more absolute forms of anorexia has been already remarked upon.

The uncontroUorable vomiting of pregnancy may also at times assume a very dangerous character.\(^6\) Thus, of fifty-eight cases collected by Cartaya,\(^7\) thirty were fatal, twenty-eight were cured after abortion or

---

\(^1\) Of course this must not be confounded with those simulated forms of anorexia where the patient eats by stealth.
\(^2\) Schmidt's Jahrbücher, 1855, iv. 60.
\(^3\) See a case by Sir C. Scudamore, quoted by Dr. Garrod, "Gout," p. 503.
\(^4\) An interesting case of this kind is quoted by Henoch, from the third edition of Romberg's work. Henoch says that in some cases of cardialgia the pain has been known to occur only at the menstrual periods, to cease with pregnancy, and to return after delivery.
\(^5\) Loc. cit. i. 539.
\(^6\) τά σπασμάτεα καὶ τετανώδεια πυρετός ἐπιγενόμενοι λύει. (Hippoc. Prænotiones, Works, Kühn's Ed. i. 289.)
\(^7\) "Progrediunt etate cardialgia crebro sponte evanescit; multas novi mulieres que tempore juventutis et ætate florente frequentissime hoc male macerabantur, ad senium pervenas ab eo omnino immunes viventes." (Schmidtmann, loc. cit. iii. 207.)
the death of the foetus—fourteen of the latter having had premature delivery induced with success, while one recovered after the application of leeches to the os uterri, and two through the use of champagne.

The Pathology of the functional disturbances of the stomach of which the description has here been given, is involved in the obscurity which attends that of a large class of nervous affections, and of which, indeed, it may be said, that our knowledge consists rather of isolated facts than of comprehensive inductions. Many of the leading phenomena attesting the influence of the nervous system in the production of the symptoms here alluded to, have been already considered, and the author has but little to add to what has been before stated, except to pass briefly in review some of the better known conditions of nervous disturbance which are applicable (in many cases, however, only inductively) to these affections.

It is well known that excessive excitability of the nervous system stands in an almost inverse relationship both to the due co-ordination and to the efficiency of the functions under its control, and that conditions of weakness or mal-nutrition of the nervous centres are evidenced by perversions in the harmony of their action characterised by an apparent excess of activity in one direction, but attended by deficiency in another.

Both the sensory nerves, and also those supplying both the voluntary and involuntary muscles (including among the latter the contractile coats of the blood-vessels), are subject to similar perversions of action. Thus it has often been noticed that when any part is the seat of severe pain, its power of distinguishing sensations is proportionately impaired, and local hyperaemia very frequently ensues. Hyperæsthesia is also occasionally combined with muscular paralysis or with convulsive movements, as may be sometimes observed in neuralgias of the fifth nerve.

The experiments of Lister and others have shown that the actions of the visceral and vasomotor nerves are exalted by impressions of moderate intensity made on the nervous centres, but are paralysed when these are carried to extreme degrees of stimulation. It is further highly probable that these impressions can be equally produced by peripheral stimulation of the sensory nerves as by direct excitation of the central roots of the motor fibres; and, therefore, the reflex effect resulting from the former will depend not only on the sensibility of the peripheral branches, but also on the degree of excitability of the nervous centres. Hence when this excitability is excessive, the effects of a moderate peripheral stimulus will resemble those produced artificially by excessive direct stimulation in the

1 Thus (to cite familiar instances) a muscle in violent convulsion is unable to execute voluntary movement—a weak eye is conscious to a morbid degree of the impression of light, while its power of distinguishing objects is diminished—mental excitement, attended with rapid thought and vivid imagination, is generally deficient either in perspicacity of ideas or in the power of sustained attention or of logical precision.
healthy state, and will give rise to paralysis or convulsion according to the proportion borne between the amount of stimulus and of the excitability present. Dr. Handfield Jones\textsuperscript{1} has also added some reasons for believing that vasomotor paralysis, determining excessive secretion, may co-exist with undue irritability of other nervous branches, since excessive secretion from the eye and nose are known to be frequently attended with hyperesthesia of the sensory nerve of these parts. If this view be correct, it is comparatively easy on the data above given to frame an hypothesis, with relation to these affections of the stomach, explanatory of the phenomena of hyperesthesia associated with secretions either excessive in amount or perverted in quality, and also with spasmodic movements indicated by vomiting, and occurring in conditions signalized by morbid excitability of the nervous centres. The cases also in which reflected nervous action is observed to proceed in unusual, and probably in abnormal directions, appear to be explicable by the same data, and are further illustrated by some striking examples of such occurrences in parts more directly accessible to observation.\textsuperscript{2}

The effects of anæmia as a cause of local pain, to which some allusion has been made by recent writers, and especially by Dr. Anstie, may possibly serve in some cases to explain the sensation of pain felt when the stomach is empty, and also its relief by food, which causes an increased afflux of blood to the part; and it is not without its parallel in the neuralgias of other parts, which are cured by a blister placed on the course of the nerve, or directly on the seat of pain.\textsuperscript{3}

Of any special anatomical conditions discoverable in these cases we are as yet in ignorance; in fact, the absence of these constitutes their distinguishing feature, as contrasted with those cases where such lesions are found to explain the phenomena observed during life.

The question regarding the possibility of organic disease resulting as a consequence from long-continued disturbances of function, excited through the nervous system, is of very considerable importance, but distinct clinical evidence of any anatomical lesion of the stomach having originated independently from this cause is very defective; and the general question is of too wide an extent to permit of its appropriate discussion in this place.

**Diagnosis.**—The diagnosis of the several forms of nervous disturbance from those arising from the organic diseases, (the symptoms of which they more especially simulate,) is often a matter of extreme difficulty.

(a) The chief criteria upon which reliance must be placed, are the recognition of a constitutional state predisposing to nervous excitability,
and particularly the presence of conditions of great exhaustion or the hysterical diathesis.

(b) The presence of causes of sympathetic irritation and the aggravation or alleviation of the symptoms of the stomach affection in a direct ratio with an increase or diminution of the severity of these.

(c) The disproportion observed between the severity of the gastric symptoms and the general state of the patient, and particularly the absence of emaciation when severe vomiting forms a prominent feature. The evidence from cachexia is of less value, since anaemia is frequently associated with nervous disturbance; and chlorotic females, whose menstruation is disordered, are frequently the subjects of ulceration of the stomach.

(d) In the case of pain, its frequent complete remissions are almost diagnostic of the absence of inflammation, though by no means excluding the possibility of its cause being due to either ulcer or cancer. Pain from inflammatory affections, unless due to corrosive poisons, seldom, however, presents the intensity of suffering produced by neuralgias of the stomach. The seat of the pain, and especially of tenderness, requires careful investigation; and when this is exclusively superficial, it would strongly favour the opinion of the nervous character of the disorder, even when under these circumstances it is allied with vomiting.

(c) Pain occurring when the stomach is empty, and relieved by food, is almost distinctive of its nervous origin. Exceptional cases of this nature have indeed been observed in ulcer and cancer, but they are of great rarity. The influence of the nature of the food upon the pain, and also upon vomiting, is another criterion, which is not without value. It has, however, been occasionally noticed in exceptional cases of ulcer, that stimulants have given relief.

(f) The co-existence of other neuralgia, and the alternation of pain with these, are also a strong ground for suspicion that the affection of the stomach belongs to the same class. Intercostal neuralgia is, however, of minor value as a means of distinction, as it may be observed in some cases of ulceration. Dorsal pain is common in both classes, and affords but few positive features of distinction between them. Spinal tenderness, though commonly present in cases of neuralgia, is occasionally absent, while on the other hand it may exist in cases of ulceration. The presence of other neuroses is also a valuable aid, though it must be remembered that in some females excessive sensibility may co-exist with an inflammatory condition of mucous mem-

1 I have known, in some cases where, from the presence of haematemesis and of severe pain occurring immediately after food, there was the strongest suspicion of the existence of ulceration, there was yet great superficial tenderness. Careful examination, however, revealed the existence of tenderness on deeper pressure in limited portions of the epigastric region.

2 See Briquet's cases, before quoted.

3 A craving for food is sometimes experienced in cases of chronic catarrh, and also of ulcer; but when yielded to, it usually aggravates the uneasiness. There are, however, exceptional cases of an hysterical character, before alluded to, where, though a strong desire for food exists, it is speedily followed by vomiting.
brane, and that in such cases the recognition of the latter is of great importance in relation to treatment.

(g) Vomiting from nervous disturbance often resembles that arising from cerebral causes in the facility with which the act takes place, and particularly in the absence of relief to the pain or nausea which attends the evacuation of matter irritating a stomach which is the subject of organic disease. The co-existence of pyrosis with pain affords but little conclusive evidence as to its origin, since this symptom may arise from causes both of organic and of purely functional nature, the character of which must be determined by the attendant symptoms.

(h) The absence of pyrexia usually distinguishes these affections from those of inflammatory origin, though it is of no value in their diagnosis from ulcer and cancer, in which disorders a febrile state is very seldom observed except from the presence of some other inflammatory capable of exciting it.

(i) The state of the tongue usually serves as an additional guide in the diagnosis from inflammatory affections. It is usually unaffected when the disturbance is of nervous origin; its characters in the catarrhal states have been already described.

On the other hand, the tongue is of little value in the distinction of the neuroses of the stomach from ulcer and cancer, where the appearances which it may present are very uncertain, and depend more on the presence or absence of the complication of catarrhal states than on any other cause.

(j) The diagnosis of severe attacks of spasm in gouty cases from those of inflammatory origin is one of considerable obscurity, as the intense depression often masks to some degree the inflammatory symptoms. The chief symptoms which should create suspicions are febrile disturbance, a loaded tongue, tenderness on pressure at the epigastric region, and burning or heat at the stomach, as distinguished from the cramp-like pain which usually marks the attacks of a more spasmodic form.

The Treatment of the various forms of nervous disturbance of the stomach may be briefly summarised as consisting in modifications of the tonic and stimulant plan already recommended for atonic dyspepsia; and their cure under this system affords further and valuable evidence of their true nature.

The discovery and cure of any source of peripheric irritation from which the symptoms may originate is of the very first importance. It does not, however, seem necessary to do more than to remind the reader of the frequency with which in the female sex these diseases have their starting-point in uterine disorders. It will, however, conduce somewhat to perspicacity if the remedies which may be more particularly directed to the condition of the stomach are mentioned in relation to the symptoms for which they have been found most efficacious.
In the relief of neuralgic pain iron holds a prominent place. In the majority of instances the neutral preparations, and especially the carbonate, are both the most serviceable and also the safest. The dose should not exceed five grains, since larger ones often provoke colic and intestinal disturbance (Trousseau). Some writers, however, as Abercrombie, Dr. Handfield Jones, and Henoch, recommend the sulphate in doses of one to two grains. Henoch advises that it should be used in combination with morphia, and Abercrombie with aloses and pulv. aromat. taken twice daily, and the latter formula will at times be found serviceable when constipation is present.

Nux vomica is very useful in these cases, as also in some forms of pyrosis.

Bismuth and the nitrate and oxide of silver are also valuable. Hydrocyanic acid has appeared to the author of inferior efficacy in relieving either pain or vomiting of nervous origin.

The utility of opium in painful affections of the stomach can scarcely be overrated, though the usual caution is necessary with respect to its habitual use. A single dose will often permanently relieve pain of many days' standing, and its value has been strongly insisted upon by most writers on these disorders.

It is of special use in gastrodynia arising from anxiety and exhaustion, but its value is not inconsiderable in many hysterical cases; and it has been remarked that, when it agrees, its effects in producing constipation are scarcely perceptible.

In pyrosis, bismuth combined with opium seldom fails to relieve; though, in order to complete a cure, a more direct astringent is sometimes necessary, and for this purpose the compound kino powder is the best remedy that can be employed. Pain from flatulence is in these cases best treated by ether or by aromatic spirit of ammonia, and the former agent is sometimes useful in checking hysterical vomiting. Trousseau speaks highly of the use of valerian and asafoetida in the wearing uneasiness which he terms "anxiété épigastrique."

In the general irritability of the nervous system, associated with dyspeptic symptoms and oxaluria, which occur among the effects of anxiety or exhaustion, the sulphate of zinc, first recommended by Dr. Golding Bird, and the oxide subsequently used by Dr. Marcet in cases where the same symptoms have followed the use of alcohol, and even in some where the latter cause has not existed, often prove of considerable service. They both seem to act as "tonics" in this condition, and the oxide has the additional advantage, if given at bedtime in doses of from two to three grains, of procuring sleep.

When the pain is very severe, relief has sometimes been experienced from the application of plasters of belladonna or of opium to the epigastrium, or from counter-irritation in this region by means of croton

1 See especially Andral, Clin. Méd. ii. 223, and Dr. Martin's case, before alluded to.

DISEASES OF THE STOMACH.

839

oil or blisters, and the latter may be followed by the endermic application of morphia.\(^1\)

In obstinate cases it may be well to try Briquet's recommendation of faradisation.

Vomiting is sometimes a very difficult symptom to overcome, and the possibility of its fatal termination has been already alluded to. When very severe it is important to give the stomach rest by the employment, during a certain period, of nutritive enemata, a plan which should never be omitted when vomiting, from whatever cause, is severe and obstinate. The value of rest is further illustrated by a case quoted by Sir T. Watson and other writers from William Hunter,\(^2\) where a boy, reduced to an extreme degree of emaciation by constant vomiting, attended by severe pain, was fed by spoonfuls only of milk frequently repeated, with the effect of completely arresting the vomiting, and enabling the stomach to bear more substantial food, the result being that the patient was completely cured; and numerous cases since recorded have confirmed the advantages of this method.

Opium is often of considerable value, and I have known a few doses of three or four drops of laudanum speedily check vomiting resulting from disease of the uterus, which had persisted for some weeks previously. It may be given an hour before meals, and in severe cases its administration by enemata may often be resorted to with advantage.

Iced effervescent drinks, combining the effects of cold with the sedative\(^3\) effects of the carbonic acid, also prove useful; and benefit is sometimes experienced from the use of champagne, and also from effervescent draughts containing hydrocyanic acid.

Bismuth, as has been remarked by other writers, is of comparatively little service when vomiting is purely sympathetic, and particularly when it arises from disorder of the uterus; but when any inflammatory state is present and complicates the nervous disturbance, it may often be employed with advantage combined with hydrocyanic acid.

The oxalate of cerium (first introduced into practice by Sir J. Simpson,\(^4\) of Edinburgh) has been found very efficacious in some cases of vomiting in pregnancy. It should be given in pills in doses of one or two grains.

In many of the milder cases of acid vomiting or troublesome heart-burn of pregnancy, hydrochloric acid combined with tincture of nux vomica, given before meals, often proves of service. I have seen less benefit result from the use of the acid alone; and part of the efficac-

---

1 It is probable that in many of the cases where the efficacy of such remedies has been reconized, the pain so relieved has more truly been seated in the abdominal muscles, where, as before remarked, its presence may complicate the gastric pain. In some of these cases the hypodermic injection of one-sixth of a grain of morphia over the seat of tenderness has afforded relief, and I have known this plan to be most efficacious in the severe pain associated with a cancer of the stomach which had formed adhesions to the anterior abdominal wall.

3 Pereira, Mat. Med. i. 125. Sir J. Simpson's Obstetric Works, ii. 769.

4 Sir J. Simpson's Obstetric Works, i. 313.
ciousness of the remedy is in my opinion due to the influence of the 
mux vomica.

Pepsine is also occasionally of value in these affections, though the 
mode of its operation is not very intelligible; but the administration 
of one or two doses is sometimes sufficient to enable the food to be 
retained, and the habit of rejecting it, being once broken, seems in 
some cases to be the essential feature of the cure.1

Among other remedies that have been found efficacious in hysterical 
vomiting, are the douche, shower-bath, or cold affusion to the body 
and abdomen.2

In the vomiting of pregnancy, Bretonneau reports that he has found 
great service from frictions of belladonna over the hypogastric region;3 
and the applications of the extract to the cervix uteri has been made 
with the same intention by Cayeaux4 with good effect.

Acupuncture has also in some cases been efficacious,5 and in others 
faradisation6 has been found of value.

The internal administration of tincture of iodine has been known to 
check the vomiting of pregnancy,7 but it does not appear to have been 
tried in this country, and I have no experience of its efficacy.

Finally, it must be recollected that troublesome vomiting apparently 
of the same kind may sometimes be caused by constipation, and that 
the use of aperients may be absolutely necessary to overcome it. In 
these cases the mixture of carbonate and sulphate of magnesia in 
doses of a scruple of the former to two drachms of the latter in some 
aromatic infusion should be administered repeatedly every four or 
six hours, or castor oil may be taken on several successive mornings 
until the bowels have acted freely.

The foregoing list, though affording a great variety of choice, indi-
cates also that there are probably concealed differences in the nature 
of the affections for which they are found useful, which are not as 
yet fully elucidated. The more ordinary kinds of neuralgic pain, when 
independent of causes of reflex origin, are as a rule easily controlled 
by iron, nux vomica, opium, ether, nitrate or oxide of silver, hydrocy-
anic acid, or bismuth; but it is in the cases of severe hysterical pain 
and vomiting, or where these symptoms originate from causes of irri-
tation in distant organs, that the greatest difficulty is experienced, and 
in these there is a considerable degree of uncertainty in the effects of 
treatment.

In the nervous disorder of the digestion which has been described 
as associated with diarrhoea, opium before meals, or administered in 
a clyster at bed-time, often affords relief; but I have known cases in

1 This point has been ably insisted upon by Dr. Chambers.
2 Andral, Clin. Méd. ii. 196. Barras, i. 480, quotes a case from L. Frank, where a 
lady, who had vomited her food for eight years, retained it when taken in a bath.
3 Trouseau and Fidoux, Traité de Thérap. ii. 76.
4 Ibid. i. 190.
6 Clarus, p. 840.
which the health was only finally re-established after the use of nux vomica and hydrochloric acid. Patients suffering in this manner should avoid hot fluids at meals, and abstain from tea in the evening. In fact, in most of the nervous affections which have been here described, the use of tea and coffee, and especially of the latter, is injurious, and often serves to excite pain even after it has been allayed by treatment.

The majority of cases of spasmodic pain supervening in the course of gouty attacks are to be treated with large draughts of warm water, and with ether, musk, or camphor. The sense of distension and load at the stomach, and the relief often experienced from vomiting, are not, however, to be taken as indications for the administration of stimulant emetics; for in such cases inflammation of the stomach, if not already present in some degree, is very liable to be excited by any undue irritation of the mucous membrane. It is desirable in all cases to promote by hot pediluvia or by mustard cataplasms the return of the disorder to the feet, and cases are recorded where this has been followed by immediate relief to the stomach symptoms.

IV.—Gastritis.—Acute Gastric Catarrh.

SYNONYMS.—Catarrhe de l'Estomac (Pinel); Gastritis Erythematica; Erysipelas Stomachi; Ventriculi Inflammatio (Boerhaave); Febris Stomachi Inflammatoria (Hoffmann); Febris Mucosa (Typhoid?); Inflammatory Dyspepsia (Todd); Gastrite, Embarras Gastroique—French. Magenenzündung, Magen-Catarrh—German.

DEFINITION.—An acute disorder of the stomach, characterised by depression and prostration, with or without pyrexia, by anorexia, nausea, vomiting, and in severe cases by pain after food, and depending on an inflammatory condition of the mucous membrane.

The terminology and real nature of this affection have been involved in much obscurity from the variety of the affections confounded under this title, including the specific fevers on the one hand, and on the other post-mortem softening, ulcer, and cancer of the stomach.

1 See Dr. Copland's Med. Dict. vol. ii. p. 39; also Dr. Garrod, before quoted.
There is no question but that acute typical gastritis, unless when caused by acrid poisons, is a comparatively rare affection, and equally so is the disease corresponding to Cullen's G. Phlegmonodea, when suppurative action takes place in the submucous tissue. Its milder forms, corresponding to the catarrhal affections of other mucous membranes, are, however, exceedingly common, and constitute the cause of the majority of the acute attacks of indigestion which occur either spontaneously or in the course of other diseases. The distinction, however, between the acute and chronic stages of inflammatory affections of the stomach is not always capable of being drawn with great accuracy, since, as remarked by Chomel, many persons liable to the disease may often suffer from a succession of subacute attacks, which being excited by slight causes, may imperceptibly pass into one another, and thus acquire the character of a continuous disorder.

Ætiology.—This disease is common at all ages, and in both sexes. It is said to have been observed in the foetus,\(^1\) in infancy\(^2\) also, and at the periods of dentition, it is easily excited by food unsuited to the digestive powers of the stomach, or improperly prepared by suitable mastication; and in advanced life the latter cause, together with the enfeebled nutrition of the organ, render it liable to be affected by similar influences.\(^3\)

Weakened states of the general system or of the stomach, which diminish the secretion of the gastric juice, are also frequent causes of inflammatory irritation, owing to the food introduced not undergoing its normal changes, and thus acting as a source of inflammatory irritation. Hence, among its predisposing causes must be enumerated many of those giving rise to general atony, and especially the presence of chronic exhausting diseases, or the period of convalescence from acute disorders.

A similar influence has been attributed to the effects of inanition or starvation, owing to observations of Hunter\(^4\) and Blundell,\(^5\) where the stomach in such conditions has been found softened after death.

\(^1\) Andral, Path. Interne, i. 17. Rayer, Dict. de Méd. x. 134.

\(^2\) It is important that the junior practitioner should remember, what is seldom mentioned in systematic treatises, that certain causes may affect the milk given to infants, through which it often proves a source of severe gastro-enteric catarrh. Menstruation occurring during lactation is one of these; and in infants brought up by hand on cow's milk, vomiting and purging are frequently excited when the animals are fed on turnips or mangold.

\(^3\) These remarks apply to the acuter forms alone. The only two authors, Dr. H. Jones (Dis. of Stomach, p.74) and Willigk (Prag, Vierteljahrsschr. i. p.28), who have made observations on this head, have included both recent and chronic catarrh in their statistics; and in these taken collectively, the tendency to increased frequency of occurrence with advancing age is very striking. Willigk's observations, however, only begin with ages from thirty upwards; and of twenty-three cases, by Dr. H. Jones, "eleven were past fifty years, and fifteen past forty years of life." I believe, from my own observations, that the increased frequency of gastric catarrh in the later periods of life will be found rather to affect the chronic than the acuter forms.

\(^4\) Phil. Trans. 1772, "Observations on certain Parts of the Animal Economy."

\(^5\) Quoted by Dr. Hodgkin, "Morbid Anatomy of the Mucous and Serous Membranes," ii. 309.
Andral also met with ulcerations, and other writers have mentioned that nausea and vomiting have been observed under these circumstances. Such a result is, however, by no means constant; and though it is possible that inflammation may in some cases be caused by the participation of the stomach in the malnutrition which occurs in all the tissues under such circumstances, as well as by the arrest of its normal physiological functions, yet it is more probable that in most cases it is due to the effect of food imperfectly digested after periods of prolonged inanition.

As exciting causes must be mentioned irritants of all kinds, including those whose action is purely mechanical, but especially the mineral and vegetable acid poisons, and particularly arsenic, and even tartar emetic and mustard when administered as emetics.

In the same category must be placed substances of an unsuitable character taken as food, such as decomposing meat or vegetables, or shell-fish in some special conditions—which latter seem to have a peculiar efficacy in this direction. The same effect may, however, be due to alimentary substances which are not directly injurious, when taken in excess of the digestive powers of the gastric juice, though their influence in this respect must to some degree depend upon their relative digestibility. Similar consequences may ensue from causes operating through the nervous system suddenly arresting the process of digestion, and thus reducing the food which has been taken to the position of a foreign body, and consequently an irritant to the stomach.

Drinking largely of cold water when the body has been heated is also mentioned as a cause of catarrh of the stomach. Sudden changes of temperature have had a similar influence attributed to them; and climatic conditions appear sometimes to act in the same direction, for catarhal affections of the stomach are most common in changeable weather, with cold and high winds, as in the spring and later

1 Path. Interne, i. 15. Essai d'Hématologie Pathologique, p. 82.
2 See especially a letter from Mr. Malcomson to Lord Hardinge, on the effects of a diet of bread and water on prisoners in causing total loss of appetite, constipation, or diarrhea with slimy discharges, together with fever, a swollen red tongue, and great prostration. Quoted by Budd, loc. cit. p. 96, who gives other cases.
3 See Chossat, "Rech. Exp. sur l'Inanition." Barras, loc. cit., 522; also Taylor's "Medical Jurisprudence."
4 Chossat found that pigeons in a state of starvation could not digest the food given them, and that under these circumstances they suffered from diarrhea; and other illustrations of the same fact occur in the histories of persons who have suffered from starvation. Barras (ib. 188) says that after the season of Lent, many persons suffer from indigestion. Two facts, observed by Bidder and Schmidt, deserve to be borne in mind in relation to this question, viz. that after a moderate period of fasting the secretion of the gastric juice is increased, but that after longer abstinence it is diminished.
5 The use of arsenical paper-hangings has also caused the same condition, an instance of which has come under my knowledge, where a previously healthy child was seized with violent vomiting, in which blood was brought up, while sleeping in a room so papered. Dr. King Chambers has narrated a similar case—"Indigestions," p. 217.
6 Andr al, Clin. Méd. i. 246.
7 Guipon (Tracté de la Dyspepsie, Obs. 21, p. 329) has recorded a case of a workman who, after exposure to the heat of a furnace, was seized with acute vomiting and pain at the stomach, and this accident was repeated several times.
autumn,\(^1\) and also during the severe heats of summer and early autumn.

There appears to be a certain amount of evidence to show that epidemic influences have some share in producing this disorder. Thus Sydenham describes in the years 1669-70-71-72, as coincident with dysentery, and following an epidemic of "cholera," a fever setting in with gripes, headache, a moist tongue with a thick fur and aphthae, cured in six days by purging and low diet.\(^2\) Barras\(^3\) remarked, that during the cholera epidemic of 1832, affections of the stomach were very common. P. Frank\(^4\) ascribed them to a constitutio annua, and Schmidtmann\(^5\) to a constitutio gastrica, independent of any special kind of weather. Chomel has remarked the coincidence with cholera of the cases of vomiting which he terms "dyspepsie acide grave." During the height of the epidemic in August 1866, I was much struck with the frequency of subacute inflammatory affections, corresponding in their symptoms to the state known by the French as "embarras gastrique,"\(^6\) and Barthez and Rilliet\(^7\) consider the probability of this affection and of other forms of gastro-intestinal catarrh taking place under epidemic influences, as very strong. It has also been stated that there is a special proclivity to gastro-intestinal catarrh during some epidemics of typhoid fever.\(^8\)

There are several other diseases with which inflammatory conditions of the stomach so frequently concur, that they may almost be considered as part of the general disorder. Many belong to the acute febrile affections, and although the impairment of the functions of the stomach in them is not always due to changes of an inflammatory character—nor is it easy to explain why these should be prominent in some cases and absent in others—yet the influence of some is so well marked, that they deserve to be mentioned as almost constant exciting causes of gastric disorder. Among these

---

1 Broussais (Hist. des Phleg. ii. 456, ed. 1822) says that inflammatory affections of the gastro-intestinal mucous membrane were very common in the Venetian Friuli, but many of his cases can hardly be considered as examples of simple gastritis, and would now be considered as pneumonia, typhoid fever, or acute tuberculosis. Brighton has universally the reputation of making many "bilious" during early periods of their residence there; and Dr. J. Todd (Cyc. Pract. Med. art. "Indigestion") says that these disorders are common in Turkey, Greece, Italy, Spain, Nice, Genoa, and Marseilles; and that they often follow the bise in Switzerland, the mistral in Provence, and the tramontana in Italy. Willigk (Phys Prager Viertel-Jahreschrift, ii. p. 28) gives for 327 cases of acute and chronic catarrh combined, observed in five years, the following relative frequency for the seasons:—Spring, 6.2 per cent.; summer, 3.4; autumn, 2.9; winter, 2.5.

2 Syd. Soc. Trans. i. 177, 181.

3 Loc. cit. ii. 161, 162.

4 De Curandis Hominum Morbis, i. 73—75.

5 Summa Obs. Med. iii. 300. There is no doubt that some of the epidemics spoken of by older writers, as by Elsaesser, Sarcoom, Roederer and Wagler ("De Morbo Mucose"), P. Frank and Réil, included cases of typhoid fever, "or of typhus complicated with Dysentery" (Murchison). See J. Frank, Prax. Med. Univ. Precept. 1811, vol. i. pars i. p. 244; also an analysis of this subject by Dr. Murchison, "Treatment on Continued Fevers," p. 393.

6 See also the report in the Medical Times and Gazette, July 1866, of the frequency of "embarras gastrique" during the outbreak of cholera at Amiens.

7 Traité des Malad. des Enfants, i. 717, 732, 738, &c.

may be mentioned cholera¹ and scarlatina,² erysipelas³ and measles⁴ and I have observed the same conditions in diphtheria,⁵ variola,⁶ puerperal fever,⁷ phlebitis, pneumonia⁸ and pyaemia, and, with a less frequency, in typhoid fever. It is also a common complication of pulmonary tuberculosis, this condition having been met with in 28 per cent. of a series of cases of acute and chronic catarrh tabulated.⁹

Inflammation of the stomach has also been observed to follow the retrocession of gout and of acute rheumatism.¹⁰

It may also be considered a question deserving further elucidation, whether some of the cases of vomiting in pregnancy, hitherto set down to reflex irritation, may not depend on alterations of a similar kind.¹¹

The liability of the stomach to suffer from other causes inducing constitutional irritation and febrile action is illustrated by Abernethy's observations,¹² who was well acquainted with this effect of general disturbance of the system.

The question of the possibility of nervous disturbance chiefly arising from moral emotions, acting as exciting causes of the disease, has been already alluded to. There are, however, as has been before remarked, but few authentic or uncomplicated instances of this nature recorded. That they may act as indirect causes by arresting digestion, is very

¹ Several observations on the effects of cholera in causing acute gastritis are also to be found in Andral, Clin. Méd. ii.
² Brinton, Diseases of Stomach, p. 57.
⁴ Barthez and Billiet (Malad. des Enfants, iii. 271).
⁵ Dr. Jenner has also seen diphtheria of the fauces associated with false membranes in the stomach ("Diphtheria," 1801, p. 4). This does not appear to be common, and, from Dr. Jenner's observations, it is probable that its occurrence is somewhat influenced by epidemic character. (See also Squire, art. "Diphtheria," vol. i. p. 401.)
⁶ See also Andral, Prec. Path. Anat. ii. 226.
⁷ In a series of observations where my attention was specially directed to this point, I observed catarrhal affections of the stomach in only four out of nine cases of this disease.
⁸ Originally observed by Dr. Stokes, Cyc. Pract. Med. iii. art. "Gastritis."
⁹ See chapter on Chronic Catarrh.
¹⁰ The former has not been proved by post mortem evidence. Of the latter a fatal case is recorded by Andral, Clin. Méd. ii. p. 11. I have lately observed a case where the retrocession of the pains from the joints was followed by vomiting and diarrhoea, and a similar one is recorded by Chomel, Des Dyspepsies, p. 137.
¹¹ The majority of cases where examinations after death from this cause have been recorded, speak of the stomach as showing little or no signs of disease. Virchow, however (Ges. Abhand. 778), has shown that in pregnancy the liver sometimes shows the same alterations as have been commonly noticed in the kidney, and which, under the title "Cloudy Swelling," are recognised as indicative of an inflammatory condition. This state will be described in the account to be given of the pathological changes found in catarrhal inflammation of the stomach, as frequently forming the most characteristic appearance present. In the Dict. Sciences Méd. vol. xvii. p. 382, art. "Gastrite," is recorded, by Guersant, a case of a woman dying from vomiting in pregnancy, in whom the stomach was found "très-blanche, un peu plus épaissie que dans l'état naturel, et recouverte d'une mucosité abondante."
¹² Rayer (Dict. de Méd. x. 136) says that he has observed that inflammations of the joints, the kidneys, bladder, and serous membranes had an important influence in determining gastro-enteric inflammation, which was acute or chronic according to the severity and duration of its cause.
probable; but further proof appears to be required before their direct influence can be regarded as fully established.  

The Symptoms of recent or acute catarrhal affections vary considerably in intensity according to the degree of severity of the attack. They may be generally comprehended under the following category:—Uneasiness, distress or pain at the epigastrium—the latter symptom being however occasionally wanting, or not present to any marked degree, even in some of the severer forms of the disease; anorexia more or less complete, vomiting, thirst, general malaise or prostration, headache, febrile reaction of variable intensity, thirst, constipation in some cases, diarrhea in others. Beaumont’s observations have shown that in slighter cases of this nature local uneasiness may be completely absent, and the disorder of the stomach may only be revealed by general malaise accompanied with slight headache. There are also differences observable in the character of the attacks, and the disorder may be described as existing in certain typical forms, between which, however, every shade of variety or resemblance may in different cases be found to exist. The principal of these are:—

(a) Acute indigestion and the "embarras gastrique" of the French authors.

(b) Febrile forms in which the fever is secondary to the disorder of the stomach.

c) Acute catarrh in infants.

d) Severe inflammation resulting from irritant poisons.

e) Catarrhal affections of the stomach, complicating the exanthemata and other acute diseases.

(f) Acute catarrh of the stomach arising from alcoholic excess.

(g) Gouty inflammatory affections of the stomach.

(a) Acute indigestion may assume various degrees of severity according to its cause or the previous health of the patient. In some cases it may present only the phenomena of a trifling "bilious" attack; in others it may last many days or weeks.

Its origin will ordinarily be found in some of the causes temporarily disturbing the digestion; a moral emotion, or severe exercise after a meal, indigestible food taken in excessive quantity, or food against which an idiosyncrasy exists on the part of the patient, are, however, among its most frequent causes. The first symptoms generally are a sense of fatigue, together with malaise, aching in the back or limbs, and depression of spirits; these are soon followed by epigas-

---

1 With the exception of the case previously quoted from Andral, the recorded observations of this nature are chiefly in older writers. (Hoffmann, De Inflamm. Ventris Frequentiss. Op. vol. vi. 223-227; Blasius, Obs. Med. Anat. Rariores; Barry, Acta Reg. Soc. Med. Hannov. vol. iii., all cited in Copland’s Dictionary.)

2 Many of these authors consider "embarras gastrique" as a distinct disorder, having nothing in common with the inflammatory processes. I cannot but regard this question as set at rest by Beaumont’s observations, and think that the difference between these and severer affections is only one of degree—an opinion which is confirmed not only by their aetiology, but also by the effects of treatment.
DISEASES OF THE STOMACH.

847

tric uneasiness and distension, and sometimes by severe cramp-like pain in the stomach. During these attacks there is often a sense of faintness, the extremities are cold, and the pulse is weak, fluttering, and depressed, and the patient is often bathed in cold perspiration. Headache soon supervenes, generally frontal in position, sometimes of considerable severity, and not unfrequently associated with intolerance of light and sound. Nausea with increased flow of saliva follows, and the offending meal is rejected, accompanied by a great quantity of acid fluid, and with its expulsion the symptoms may cease. In other cases, instead of being vomited, the irritating matters pass into the intestines. Griping and colicky pains then ensue; in some cases a spontaneous diarrhoea is set up, which carries off the pecant material, but in others constipation, associated with flatulence and spasmodic contractions of the intestines, continue until the bowel is evacuated by a purgative. In the latter cases, pain, sometimes acute, is felt at the epigastrium; or there may be only an excessive sense of uneasiness and of weight or load at the precordial region. There are complete anorexia and loathing of food, and nausea continues, often attended with ineffectual attempts to vomit. The tongue becomes loaded with a thick creamy fur; and though the amount of this varies in different cases, being sometimes thin enough to allow the enlarged papille to appear through, it always retains its soft, moist, milky appearance; the breath is offensive, and thirst is generally a marked symptom. In other and severer cases the circulatory and nervous systems may participate in the general disorder; palpitation, dyspnœa, faintness, vertigo, or a confusion of ideas may supervene; and when in the case of elderly people an excessive amount of flatus is generated, cerebral congestion may occur to an extent sufficient to simulate an apoplectiform attack; while in children, and sometimes also in females, the implication of the nervous system may induce convulsive affections of the epileptiform character.

The headache which appears in the course of the slighter attacks of this nature, often assumes a form with somewhat characteristic features, and which is familiarly known as the "sick-headache." It is most common when acute exacerbations are superadded to the ordinary forms of atonic dyspepsia; and hence it is most liable to affect those who are out of health, and whose digestions are weakened by sedentary employment, and who have a tendency to costiveness. It occurs, however, also in persons of apparently vigorous health, sometimes without apparent cause, but most usually after some indiscretion in diet, or after some of the causes liable to arrest the digestive process.\(^1\)

The most usual time of its appearance is some hours after food has

---

\(^1\) Fothergill, who first described this headache (Med. Obs. and Enq. vol. vi.), attributed to "butter, fat meats, spices," and "meat-pies," a special faculty in its production. Wood (Practice of Med. i. 564) says that it is frequently caused by excesses in the use of tea and coffee, but especially of the latter.
been taken, and very commonly the patient wakes with the pain at an early hour in the morning, especially when the last meal has been a late and indigestible supper. It may, however, supervene at any hour of the day. The attack is usually preceded for a longer or shorter period by some indistinctness of vision, sometimes affecting half the field of vision of one or both eyes; at other times diplopia occurs, or sight is disturbed by muscae or by dazzling spots of light. Vertigo and noises in the ears may also appear among the prodromata. These are usually soon followed by pain in the head, at first slight, but rapidly increasing, until it becomes of great severity, which most commonly affects one or both temples, the frontal or in rarer cases the occipital region. There is often acute throbbing pain in the eyeballs, which are tender to pressure, though when the pain in the head supervenes the indistinctness of vision usually disappears. If the pain lasts long the scalp sometimes becomes tender, and it not unfrequently remains so for some time after the attack. During the paroxysm the surface of the head, and particularly the forehead, is often cold, and in some cases the pain itself may be partially relieved by hot fomentations; at a later period the skin of the head generally becomes hot.

Other symptoms accompany the attack. The physical and moral depression is, in severe cases, extreme; light and sound are equally intolerable; sighing, yawning, or shuddering are often present, together with an extreme sense of general chilliness, amounting at times to rigor. Nausea is very common, and vomiting of acid food sometimes occurs—this appears sometimes, but by no means constantly, to relieve the patient. In other cases there is a great sense of uneasiness in the lower bowels, leading to ineffectual attempts at evacuation, and the only effectual mitigation in such cases is that produced by a purgative. The attack may last only for an hour or two, or may persist for twenty-four or forty-eight hours. When it is severe, complete relief is rarely obtained until after sleep has been procured, though this is unattainable during the height of the paroxysm. After sleep the patient awakes either free from pain, but feeling weak and nervous, or sometimes with a dull aching in the head, which gradually disappears. A loss of appetite, and diminished digestive power, which sometimes entails a liability to a speedy recurrence of the attack, often remains during some days.

The nature and immediate causes of these attacks has been a subject of much discussion. Dr. Anstie has recently adduced some good reasons for regarding the pain, when seated in the anterior part of the head, as a neuralgic affection of the fifth nerve, and it is not impossible that this may be its real explanation, since other neuralgic of this nerve have been observed to follow disturbances of the stomach. It would appear that these headaches may be immediately produced by undigested food, either remaining in the stomach or which has already

"On certain Painful Affections of the Fifth Nerve," Lancet, 1866, ii. 32.
passed into the intestines; and this opinion is corroborated by the methods through which relief is usually obtained. Whether any special conditions of the food or of the secretions are concerned in its production must remain, as heretofore, in the absence of positive data, a matter of speculation.

Anorexia, pain, and thirst, with a loaded tongue and great general depression, may sometimes continue for days, owing to undigested food being retained in the stomach, and may disappear after this has been evacuated by an emetic, but in other cases the irritation remains long after its cause has been removed. The persistence of the symptoms above indicated, with certain others superadded, then form the "status gastrius," "saburnal condition," or "embarras gastrique" of the French and German, which may in most cases be traceable to some of the causes above indicated, but in others it occurs apparently spontaneously, or it may result from fatigue, over-anxiety, or probably from some of the epidemic influences before alluded to. There is then tenderness, load, and uneasiness at the epigastrium, together with great disgust for food, which, when taken, increases the distress, or causes nausea, and sometimes vomiting of mucus, or bile, or food acid from fermentation, together with acid watery fluids. Thirst is a marked symptom, and there is sometimes a craving for acid drinks; the tongue is more or less thickly covered with a moist white or brown fur; there is a bitter, nauseous, and sometimes metallic taste in the mouth, and an increased flow of saliva has been occasionally noticed. Fetid and acrid eructations and heartburn are often complained of, and the breath is heavy and offensive. The bowels are, as a rule, confined. In some cases diarrhea may have been present at the outset, with colic and griping, but on ceasing it is followed by constipation; in rarer instances, in which catarrh of the intestinal canal is also present, it persists throughout, and is then attended with griping, and with pale watery stools, which often irritate the anus and rectum when passed. There is great physical and intellectual oppression, together with a sense of fatigue and weakness, which may be the sole symptoms felt by the patient, or for which relief is sought; or these may be accompanied by a dull, confused headache, becoming sharper at intervals and not relieved by sleep. Sleep is unrefreshing, and is disturbed by dreams or nightmare. There are often rigors and slight horripilation of the skin, especially towards evening, with a certain amount of febrile reaction, ending sometimes in acid perspiration during sleep: an icteric tint of the conjunctivæ is very common. The pulse, except during febrile accessions, is generally depressed and weak, and slower than natural, though easily accelerated on slight exertion. If fever supervenes, it becomes quick and full, but easily compressible. Urticaria and herpes sometimes complicate these attacks: the former is often caused by shell-fish, or by substances against which the patient has a special idiosyncrasy;¹ the latter, when appearing in connexion with acute

¹ Mushrooms, cucumbers, almonds, oatmeal, pork pie, and mackerel (Budd, loc. cit. VOL. II.)
attacks of indigestion, mostly affects the alæ nasi, the lips, and chin, and more frequently results from the use of malt liquors in persons with whom these habitually disagree, than from any other single cause with which I am acquainted.

The urine is usually scanty, acid, high-coloured, and loaded with lithates on standing; it may in some forms of acute indigestion occasionally present traces of albumen.

The duration of such an attack is uncertain: when appropriately treated, it usually terminates in a few days, though a certain irritability and weakness of digestion may continue for some time after; but when neglected, or when food is indulged in as usual, or if alcoholic stimulants are taken in excess to relieve the flatulence or feelings of prostration accompanying the attack, it may be prolonged almost indefinitely in a subacute form.

(b) There are, however, severe forms of the disorder, marked by considerable febrile reaction, which are very difficult to distinguish from febricula, or sometimes from early stages of typhoid, but in which the febrile reaction appears to be in reality attributable to the stomach. One class of these cases is marked by epigastric pain of some severity, which is generally central, but which sometimes radiates into the hypochondria and extends to the back. The sensation is sometimes one of heat or burning, at others of load or constriction; but as a rule it does not present the same degrees of intensity as are observed in nervous gastrodynia or in the pain from ulcer and cancer. In other instances, however, pain is not complained of. Vomiting also occasionally occurs, and may be almost constant after everything taken, and be brought on even by the smallest amount of liquid—the matters rejected being mucus, sometimes tinged with blood; or bile in considerable quantities; and retching may continue even after the stomach has been emptied. The tongue in these cases may present the loaded saburreal state before described, but it tends in a day or two to become red, raw-looking, and sometimes fissured; the papillae are large and red, and the lips dry and cracked. Sordes sometimes appear on the teeth.

Thirst is usually considerable, and the appetite is completely lost.

Constipation generally persists, and sometimes with considerable obstinacy; but diarrhea may occur, though this is comparatively unfrequent.

Rigors, to a mild degree, usually continue throughout the whole course of this affection. The skin is often hot to the hand, but except in cases of children the elevation of the temperature is rarely consider able, and seldom above 100° Fahr. There is generally a considerable exacerbation of fever in the evening, and the diurnal remissions

266). Cubebs also has been known to cause it (Wood, Pharmacologia, i. 331). In some of these cases the invasion of the nettle-rash is not always accompanied with the signs of gastric disorder here mentioned. Herpes zoster, though preceded often by severe constitutional disturbance, is not so common a phenomenon of these attacks.
may be almost complete. The pulse is frequent, but weak and compressible.

Prostration with restlessness, and pains, though only of moderate severity, in the back and limbs, also continue throughout the attack; and the headache, which is ordinarily frontal, is frequently severe. Sleep is usually disturbed; and in children delirium may supervene, or a semi-comatose condition may be observed, and strabismus occasionally occurs. I have never observed either slughishness, or marked contraction, or inequality of the pupils. The urine is scanty and high-coloured, and deposits lithates.

Cough is spoken of as a common complication. I have not observed this unless when from a common exciting cause, such as cold, a bronchitis has been set up simultaneously with the gastric catarrh. Cough, associated with pyrexia, should always be regarded as a symptom requiring a careful and suspicious investigation of the lungs, for the condition which has now been described is often the accompaniment of early stages of phthisis.

The duration of this complaint, in its acute form and under proper treatment, is seldom longer than a week or ten days; but if treated at the outset with tonics and alcoholic stimulants, it is liable to become almost indefinitely protracted, and to pass into some of the more obstinate forms of chronic catarrhal inflammation.

(c) In young children, especially in infants under six months, or at the period of weaning, improper or excessive food sometimes causes a general catarrh of the whole gastro-intestinal canal. This may find its chief expression in diarrhoea, which frequently precedes the vomiting; but in many cases the latter is often an important, and even a dangerous symptom. There may be but little fever, and even when the skin over the abdomen is hotter than natural, the extremities and lips may be cold and bluish; and though the abdomen is sometimes tender, this is not constantly observed. Pain is, however, frequently evinced by cries, especially before the evacuations. These are liquid, watery, offensive, acid, and often grass-green in colour; they generally contain masses of coagulated casein, and are often attended with straining or tenesmus; but when the attack is severe and the child much prostrated, they may be passed apparently unconsciously. The vomited matters consist of the coagulated milk, returned in an intensely acid condition, and accompanied with much acid watery fluid. Thirst is frequently excessive, but fluids taken are often rejected almost as soon as swallowed. The patient rapidly loses flesh, and great prostration sets in early, so that the infant may have difficulty in sucking, though it drinks with avidity. The pulse becomes weak and fluttering, the fontanelles are depressed, the countenance is pale, the eyes are sunken, and the features have a peculiar pinched, sharpened appearance. Somnolence, passing into coma or convulsions, may at times complicate the other symptoms, but the latter phenomena are not frequent. The course of this form is acute, and, if not early checked, it tends towards a fatal issue.
I have occasionally observed affections of this nature, though of somewhat less severity, and occurring at the period of the first dentition, alternate in a remarkable manner with eczematous affections of the skin.\(^1\)

It may be remarked that the symptoms of the choleriform diarrhoea of children correspond to a great degree, as far as regards the stomach, with those observed in true cholera in the adult. In the majority of the cases of this disease which have come under my observation, the stomach participated markedly in the catarrhal condition of the intestines,\(^2\) and the thickly-furred tongue in many corresponded most closely with that of the "saburral" conditions which have been before described.

It appears, however, unnecessary to enter into fuller details of the symptoms of this affection, though it is not unimportant to bear in mind its pathological relationship to the class of diseases which we are now considering; and to remember that the diseased conditions excited by cholera may persist in the stomach long after the other leading features of the disorder have subsided. This has been observed by numerous writers, especially by Andral, Budd, and Chomel; and their experience can, I have very little doubt from my own observations, be confirmed by any who have had opportunities of following the history of patients who have been subjects of the latter disease. Chomel's\(^3\) "dyspepsie acide grave," with its acid vomitings, is the counterpart of that observed in children; but I have great doubts whether such acidity is the result of hypersecretion, and not rather the consequence of rapid catalytic changes in the food taking place under the influence of the unhealthy secretions of the stomach, especially as in some cases recorded by other observers it was found to be greatly increased by farinaceous food.\(^4\)

\((d)\) The symptoms of the typical acute form of gastritis are merely exaggerations of the milder varieties just described, the gradations observed consisting principally in differences in the degrees of severity; but the more marked characters of the disease are rarely met with, except when the more violent irritants have been swallowed.

There is usually acute epigastric pain, though some remarkable exceptions have been observed in this respect by Dr. Habershon, even in cases where corrosive poisons have been taken.\(^5\) Its characters are burning and lancinating; it often extends into the back, and, when the affection is severe, it is not relieved by vomiting, and is increased

---

\(^1\) In one case, in a strong and otherwise healthy child, the eruption of each tooth was either attended with an attack of acute eczema, or by an attack of vomiting with diarrhoea; and during one of the latter, the gastro-intestinal symptoms suddenly ceased on the supervision of the eczematous rash. It appears difficult to explain these phenomena, except on the theory of some \textit{materies morbi} in the blood finding an excretory outlet by the skin or mucous membranes.

DISEASES OF THE STOMACH.

by pressure. It is often accompanied by spasm and rigidity of the abdominal muscles, and is aggravated by each descent of the diaphragm, so that the respiration frequently becomes wholly thoracic.

Vomiting is a constant symptom: it is frequent, and is brought on by the smallest quantity even of cold fluids. There is also violent retching, which continues when the stomach is empty. The matters brought up are mucus, often tinged with blood, or blood blackened by the fluids of the stomach, together with bile and watery fluids. Diarrhoea is present in some cases, together with colic, tenesmus, and bloody stools, especially after arsenic, antimony, or corrosive sublimate have been taken;—absent, or not so commonly met with, after the mineral acids, and caustic alkalies. There is complete anorexia, but great thirst. Prostration is marked, but often combined with agitation and restlessness. The face is pale and sunken, the voice weak or extinguished. The skin is cold, and often covered with clammy perspiration, and the pulse is frequent and small.

Hiccup is sometimes a very painful symptom, and may continue after the vomiting has ceased.

The duration of these symptoms is variable. Death may ensue with great rapidity by complete collapse; or the patient may linger for days and die from exhaustion; or long-continued irritability may persist for weeks, and subsequent dangers may ensue from haemorrhage, or from the contraction of cicatrices resulting from ulcerations in the pyloric region.

(e) The symptoms of inflammatory disorder of the stomach complicating other acute diseases are often considerably modified, or even masked, by the course of the disorders in which they occur. Anorexia and thirst are common to those in which we have no evidence to show that the affection of the stomach is of an inflammatory nature. I am inclined, however, to believe that in the majority of cases where, in addition to these, we find a loaded tongue and nausea after food, and even a slight degree of epigastric tenderness, this condition of the stomach is the cause of these symptoms much more frequently than is generally supposed to be the case, and I have had repeated opportunities of verifying this opinion by post-mortem examinations. In some, however—and this is particularly true of variola and scarlatina, and not unfrequently also of pneumonia—other and more distinct symptoms appear, in the form of vomiting. Spontaneous pain is not, however, usually present. Though these evidences of gastric inflammation are often more distinct in the disorders last mentioned than in some other of the acute diseases, yet, with regard to the whole class, the liability to this complication should be always recollected in considering the measures of treatment to be adopted.

(f) In the inflammation of the stomach that follows from drink the symptoms are often very obscure. Vomiting, except in the morning, is comparatively rare, and signs of tenderness can with difficulty be elicited on pressure. The loaded tongue, the absolute anorexia, and

1 It may be in some cases affected by the action of the irritant upon the epiglottis.
the thirst, serve however as signs of an inflammatory condition of the stomach, of which confirmation is afforded, in some cases of fatal delirium tremens, by post-mortem evidence, and in others, whose termination is more favourable, by the successful results of treatment directed towards this complication.

(g) Gouty attacks of inflammation of the stomach usually occur under two forms. The outbreak of the disorder is frequently complicated with all the symptoms before described as those constituting an acute attack of indigestion, which are sometimes relieved, but at others persist when one or more joints have become the seat of the characteristic inflammation. The more severe and dangerous forms, however, are those attended by a sudden disappearance of the inflammation of the joints and by a simultaneous accession of epigastric pain and tenderness, together with vomiting, and accompanied by severe prostration, and these symptoms may proceed to a dangerous extent unless relieved by a return of the disease to its previous seat. Nor does the predominance of nervous symptoms in some cases at all preclude the possibility of even these being due to the suddenness and severity of the affection of the stomach, though the extreme degrees of flatulence and spasm which accompany them are in themselves almost sufficient to account for these phenomena.1

The Pathology of the symptoms here described involves the consideration of the nature of the condition in which they originate, and of the anatomical alterations by which they are accompanied, and upon which they in all probability depend. The evidence that these changes are of an inflammatory kind is in part directly demonstrable, and in part is the result of induction. In the milder forms we have seldom, if ever, an opportunity of experimentally verifying this opinion by post-mortem examination; but the observations of Beaumont, although too often forgotten in actual practice, seem to set this question conclusively at rest.

Having been conducted on a living subject, they possess the advantage of being records not only of changes affecting the glandular tissues, but also of conditions of perverted vascularity, which in the stomach, as in external parts, are only apparent while the circulation is still maintained, and which speedily become indistinct after life has ceased.

The appearances observed by Beaumont cannot be better described than in his own words:—"There are sometimes found, in the internal coat of the stomach, eruptions or deep red pimples, not numerous, but distributed here and there upon the villous membrane, rising above the surface of the mucous coat. These are at first sharp-pointed and red, but frequently become filled with white purulent matter. At other times, irregular circumscribed red patches, varying in size and extent from half an inch to an inch and a half in circumference, are found on the internal coat. These appear to be the effect of con-

1 See Garrod, On Gout, p. 505.
gestion of the minute blood-vessels of the stomach. There are also seen at times small aphthous crusts in connexion with these red patches. Abrasion of the lining membrane, like the rolling up of the mucous coat into small shreds or strings, leaving the papille bare for an indefinite space, is not an uncommon appearance. These diseased appearances, when very slight, do not always affect essentially the gastric apparatus; when considerable, and particularly when there are corresponding symptoms of disease, as dryness of the mouth, thirst, accelerated pulse, &c. \textit{no gastric juice can be extracted}.\footnote{1} "Complained of headache, lassitude, dull pains in left side and across the breast, tongue tinged into a thin yellowish coat and inclined to dryness. Eyes heavy and countenance sallow. The villous membrane of the protruded portions of the stomach very much resembled the appearance of the tongue, with small aphthous patches, in many places quite irritable and tender."\footnote{2}

"The gastric fluids extracted were mixed with a large proportion of thick ropy mucus, and considerable muco-purulent matter slightly tinged with blood, resembling the discharge from the bowels in some cases of chronic dysentery." . . . "Flavour peculiarly fetid and disagreeable, alkalescent, and insipid."

In other places he mentions the phenomenon of minor degrees of haemorrhage as not uncommon,—"grumous blood exuding from several small points of the membrane."

It is remarkable that in many instances when these appearances were well marked, the symptoms experienced by the patient were but slight; and hence, \textit{à fortiori}, we may conclude that when the latter are more severe, the anatomical changes are more considerable, though direct evidence of this is often unattainable.

The appearances\footnote{3} thus described are, however, much less distinctly seen in post-mortem investigations; and the difficulty also of appreciating such evidences as are derived from the apparent vascularity of the organ, is often very considerable.

As regards the phenomena of the latter class, two propositions, the converse of one another, may be laid down as true with certain limitations to be immediately explained. Firstly, that considerable vascularity is not necessarily evidence of inflammatory action; and secondly, that an almost entire absence of this appearance by no means excludes the pre-existence of this process.

Evidence in favour of the first statement has been abundantly accumulated since the time of Morgagni,\footnote{4} and more fully by Dr. Yellowly in 1813,\footnote{5} who was shortly followed by Billard,\footnote{6} by Trousseau

\footnote{1} Loc. cit. p. 99. \footnote{2} Loc. cit. p. 171. \footnote{3} Pustular appearances of the glands have, however, been described by Bayer as occurring in the stomach (Dict. de Méd. x. 120), and also by Wahl (Virchow's Archiv, xxi. 579). In the latter case mucedines were found in the glands. The appearance is, however, rare, and must not be confounded with enlargement of the solitary glands hereafter to be noticed. \footnote{4} De Canz. et Sed. Epist. xxix. \footnote{5} Med.-Chir. Trans. iv.: "Observations on the Vascular Appearance in the Human Stomach which is frequently mistaken for Inflammation of that Organ." De la Membrane Muqueuse Gastro-Intestinale. 1525.
and Rigot,¹ and by Andral.² These authors have shown that partial hyperæmias and also general straining of the stomach may be determined by the position of the body, by the fluidity of the blood, and also by obstructions to its return from the abdominal organs existing in the vena portæ, the heart, or the lungs. Andral adds, that when death takes place during the act of digestion, hyperæmia of the stomach is generally found; but numerous exceptions will be found to this rule, when the examination has been made some hours after death.

Hyperæmia, of inflammatory origin, is almost invariably purely capilliform and punctiform. The latter appearance is due to small extravasations in the mucous membrane, and may arise from mechanical congestion as well as from inflammatory hyperæmia; and frequently the punctiform redness persists when the general injection, which may be reasonably presumed to have been present, has disappeared. Venous congestion and general inbibition can never, taken alone, be considered as signs of pre-existing inflammatory action. Nor is it always easy to distinguish, apart from other phenomena, the redness of congestion due to impeded return, from that which arises from inflammatory hyperæmia.

It appears, however, equally important to insist on the fact that although during life inflammation of the stomach is probably invariably associated with hyperæmia, yet that post-mortem pallor of its mucous membrane is no sign of the absence of previous inflammatory action; but that in here, as in other mucous surfaces,³ even when inflammation has existed, the blood after death leaves the small superficial vessels.

It is only when stasis has existed to an extreme degree, or when punctiform extravasation has taken place from the capillaries, that the signs of inflammatory hyperæmia persist long after death; and even when present they seldom, except in cases of extensive inflammation from irritant poisons,⁴ occupy more than patches of the surface.

Other changes, however, exist, which furnish safer criteria for the diagnosis of inflammation than can be derived from the absence or presence of vascularity taken alone. In the slightest forms they

¹ Arch. Gén. xii.
³ E.g. in the conjunctiva and in the skin after erysipelas. Andral, Clin. Med. ii. 177. Congestion of the stomach to an amount sufficient to cause hematemesis may leave no traces after death. The bronchi are almost the only exceptions to this rule; but then it should be remembered that extensive bronchitis is almost always attended with congestion of the lungs, which prevents the blood escaping by the pulmonary veins, into which those of the bronchi open. The fading of colour is probably due to the contractile tissue accompanying the capillaries, but in the stomach it is also owing to post-mortem inbibition, and to the effects of the gastric juice. For further confirmation of this opinion the author ventures to refer to a previous work, "Diagnosis and Treatment of Dyspepsia," 2d Ed. pp. 174, 175.
⁴ From many of these, as in the cases of arsenic, tartar emetic, and cyanide of potassium taken in large doses, hyperæmia is almost constantly present; but from others, as from phosphorus (Virchow, "Der Zustand der Magen bei Phosphor Vergiftung," Archiv, xxxi. p. 399), it may be absent, and yet other signs of inflammatory action, presently to be noticed, may exist to a marked degree.
DISEASES OF THE STOMACH.

are, it must be confessed, somewhat difficult to distinguish, differing, as they do, only by a question of degree from those which occur in the physiological process of digestion, in which not only the vascularity, but also the colour and consistence of the membrane are affected.

These changes consist in an increased opacity, together with swelling and with varying degrees of diminution of consistence of the mucous tissue. The two first of these are distinctly described by Beaumont; and the increased opacity gives to the mucous membrane (apart from the colour produced by hypersemia) a dead white appearance, corresponding to the "cloudy swelling" of Virchow which is observed in the kidneys in acute Bright's disease.¹

Microscopic examination of the mucous membrane in this condition shows that the secreting cells, and also the nuclei, are swollen, irregularly distending the tubules, and are filled with granular matter soluble in liquor potassae and dilute acids, which gives them, by reflected light, and as seen with a low power, the appearance of white lines, while by transmitted light they appear unnaturally dark and opaque. The cells also often contain fat globules in variable quantity, but in severe cases they often break down without undergoing fatty degeneration, and the tubes become more or less filled with granular débris and detritus.

---

¹ A case of this kind is recorded by Guersant, art. "Gastrite," Dict. Sciences Méd. xvii. 576, where a young lady died after long-continued vomiting, together with fever and abdominal pain. The mucous membrane was covered with a tenacious mucus, the glands were prominent, and the membrane thickened and moist. The membrane was whiter than in the natural state, and of the colour of lard. The vessels on the external surface were gorged with blood. The other organs were healthy. Guersant,
It is to this distension of the glands, by an abnormal accumulation of protein matters in their interior, that the swelling of the mucous membrane and the pustular appearance observed by Beaumont are chiefly due. The normal secretion of gastric juice is arrested by this state, but at the same time there is secreted a considerable amount of tenacious alkaline mucus, containing large quantities of the morphological elements of the interior of the glands, which are generally separate, but sometimes adhere in masses, and then resemble the casts of the tubes excreted in similar conditions from the kidney.¹

The softening of the mucous membrane which accompanies these changes is totally distinct from the post-mortem softenings, which are distinguished by the transparency of the tissue. It rarely exists to any marked degree, except in extreme cases, but there is always a certain diminution of resistance to the finger-nail or to the scalpel, which materially assists, when conjoined with opacity and thickening, in distinguishing this condition. 'Louis' test of the extent to which it can be torn from the submucous tissue is a less available one, and applies rather to states of post-mortem solution than to this condition.

Coincidently with these changes there is a considerable increase in size if not in number of the solitary and lenticular glands, which then appear as small white specks, varying in size from that of a poppy to a millet-seed, thickly scattered over the surface. They are most abundant in the pyloric portion of the stomach and also in the duodenum. A considerable thickening of the interstitial tissue simultaneously occurs, owing to its becoming infiltrated with cell-structures similar to the "lymphatic" elements existing throughout the intestine.² They are imbedded in an alveolar network, but are not separated by any distinct line of demarcation from the tubular structures around, which are sometimes widely separated, and more or less obscured by this growth; and these changes greatly increase both the paucity and the thickening of the mucous membrane.

![Fig. 3.—Intestinal growth of lymphatic elements between gland-tubes.](image)

not recognising the inflammatory characters of this affection of the stomach, speaks of the disease as one *incertae sedis*. Carswell, Illust. Elem. Forms of Disease, recognised the occasional pallor of inflammatory softening of the stomach.

¹ Described by Dr. Cayley, Beales, Archives, i. 198; also by Dr. Fenwick, loc. cit. in scarlatina. I have seen them in the catarhal affection of the stomach in diphtheria, and also in catarhal affections of the intestines. They are less frequent either in the stomach or intestines in cholera.

² His. Untersuchungen über den Bau der Peyerschen Driisen und der Darm Schleimhaut; Frey, Untersuchungen über die Lymphgefäße des Darm-kanals. (Leipzig, 1863.)
In some cases these structures ulcerate, and it is to this cause that the majority of the so-called follicular ulcers appear to be due. These form little cup-shaped depressions scattered more or less thickly over the surface of the mucous membrane, rarely exceeding at the surface a diameter of two or three lines, and seldom extending deeper than the submucous tissue. Their base is found to rest on a tissue infiltrated with lymphatic cells and with the granular débris of these, which may be generally also noticed for some distance in the surrounding tissue.

Other ulcerations, which are more of the nature of erosions, are not uncommon. They are more superficial, but may attain the diameter of a fourpenny piece. Their edges are often sharply defined, but there is very little thickening around them; I have never seen them extending for any depth into the tissue, and they rarely involve the whole depth of the secreting glands. They appear to arise from a superficial epithelial erosion, sometimes extending rather deeper into the tissue, and resulting probably from the process described by Beaumont as "stripping and rolling up of the membrane." Early stages of this condition are sometimes found, when in circumscribed patches, giving evidence of acuter inflammatory action; the mucous membrane is found to be superficially reduced to a pulpy débris, the separation of which would probably have led to a similar result.¹

In cases of a severe type, or when the affection of the stomach complicates septic or gangrenous inflammations in other parts, sloughs² may form on the mucous membrane, which may have a diameter of from a half to a quarter of an inch, but I have rarely seen them proceed to any depth.

² I am referring to instances entirely independent of corrosive poisons. I have seen them in gangrenous pneumonia, and similar cases are recorded by Recklinghausen (Virch. Arch. xxx.) and by Klebs (lb. xxxii.).
Smaller solutions of continuity may also arise from extravasations of blood, ending in superficial hemorrhagic erosions. These are, however, much more frequently the result of mechanical congestion than of acute inflammation.

Exsudative inflammations on the surface of the stomach seem also to be rare; I have once or twice seen them in phthisis, and Dr. Jenner has observed them in diphtheria, and Rayer says that they have been noticed in cases of "croup." Pain and vomiting have been observed in some of these cases, but no special symptoms seem to be attached to this condition enabling a diagnosis to be made.

Another and still rarer affection is that corresponding to the gastritis phlegmonodea of Cullen, which does not as yet appear to have been recognised during life, and which can hardly be included among the class of diseases which have now been described.

The leading symptoms seem to have been acute pain in the pre-cordial region, together with vomiting, violent fever, and delirium, ending speedily in death.

In cases recorded by Wallmann and Bamberger, the affection of the stomach appears to have been idiopathic, and to have been the only lesion present; but in two others which occurred in the practice of Oppolzer, it commenced with puerperal fever.

In these instances the chief anatomical character has been suppuration in the submucous tissues of variable extent, sometimes undermining the whole membrane, or perforating it in various places. Bamberger says that the abscesses thus formed may perforate other organs to which the stomach has formed adhesions, but the rarity of these affections renders them objects of pathological, rather than of clinical interest.

Special descriptions of the appearances produced by the different kinds of poisons belong rather to the questions of medical jurisprudence than to the clinical pathology of the stomach. They will not, therefore, be described in this place.

Diagnosis.—The acuter inflammatory disorders of the stomach are usually recognised without difficulty. Some of the severer forms may occasionally be simulated by the neuroses, but the chief points of distinction have been already alluded to.

The slighter forms, especially when occurring in the course of other chronic diseases, and particularly in phthisis, are more liable to be overlooked, the increased prostration and loss of appetite being too frequently referred to the effects of the general disorder. In such cases, symptoms of indigestion of food are not always prominent, and the most valuable indication of the nature of the disease is to be

1 Diet. de Méd. x. 124.
DISEASES OF THE STOMACH.

derived from the appearance of the tongue, which instead of being pale, broad, and flabby, as in the atonic state, becomes under these circumstances covered with a milky fur of more or less thickness, through which red papillae appear. Thirst and constipation are often superadded.

The diagnosis of the febrile forms from typhoid is also often difficult; and sometimes doubt must continue to exist until after the appearance of the characteristic eruption of the latter. Points which may serve to assist in the diagnosis of the earlier stages are the swelling of the spleen in typhoid, together with tenderness or gurgling in the iliac fossa. The skin also is more frequently hot in typhoid, whereas in gastric catarrh perspirations are common. The temperature also is less elevated in the latter than in the former disease. Herpetic eruptions on the lips or elsewhere, which are common in gastric derangement, are very rare in typhoid. (Niemeyer, loc. cit.)

TREATMENT.—The primary indication in the treatment of recent inflammatory affections of the stomach, is to secure for the organ as complete a rest as it is possible to obtain; and in the milder forms, a tolerably complete abstinence from food for four-and-twenty hours will frequently do much towards effecting a cure. In severer cases, and where the disorder is more protracted, or when the patient is too weak to bear abstinence, as in the case of infants, much may be effected by nutrient enemata in sparing the stomach, and allowing it the necessary repose. Such food as is taken should, when the disorder is of any severity, be restricted to milk and lime-water, or milk and soda-water, administered in small quantities every two or three hours. In cases where milk disagrees, as it does with some patients, veal or chicken broth, or beef-tea, in small quantities, may be substituted for it.

In the case of infants suckling, the quality of the milk should be carefully examined, and, if the nurse is menstruating, a change is absolutely necessary. If obtained from the cow, the diet of the animal should be restricted to hay or fresh grass. In severe cases it is desirable that the child should be withdrawn from the breast for some hours, and a small quantity of rice-water, or of milk greatly diluted, should be given at intervals. In the case of infants brought up by hand, the milk is to be largely diluted, and the addition of lime-water or of carbonate of soda is very desirable. When cow’s milk absolutely disagrees, a change to ass’s milk is sometimes sufficient to effect a cure; but this is, not always the case, and medicinal treatment is often further necessary. A small quantity of farinaceous food, as arrow-root, sago, or gruel, may often be given with advantage with the milk; it appears to act beneficially by preventing the coagulation of the casein into lumps in the stomach.

In cases of less severity, in older children or adults, the lighter farinaceous puddings may be allowed. Solid animal food is decidedly to be prohibited as long as any nausea or pain at the epigastrium
is caused by food entering the stomach; and when the needful rest of body is enjoined, this enforced abstinence may often be protracted during some days with decidedly beneficial effects. The return to a more nourishing diet is always to be effected gradually, and with caution. As the symptoms subside, the patient may be allowed a small quantity of fish, or minced chicken, eaten with bread, but without (at first) any vegetables, and he may gradually proceed to game, or tender mutton, taken once in the day; but it must be remembered that any indiscretion or excess in diet is very likely to bring on a relapse.

Alcoholic fluids are decidedly to be avoided except where great prostration is present. When a stimulant appears to be urgently required, brandy is usually the best form in which it can be given; and in the case of children, and even in infants, it may sometimes be advantageously administered, properly diluted, or combined with beef-tea or milk, by the rectum. Champagne also is occasionally found to be advantageous in checking vomiting; but it is less efficacious when this symptom is due to inflammatory action than when it arises from sympathetic irritation, or from the erethism of exhaustion.

Rest of body is equally essential, and in severer cases, and particularly when diarrhœa is present, the patient should be kept in bed until the more urgent symptoms have subsided.

General bleeding is decidedly inadmissible, as the disease ordinarily tends to produce considerable prostration, and any large loss of blood is likely to entail serious consequences, and to retard the recovery of the patient. When pain is continuous, and appears to be unassociated with the presence of undigested food, but to be increased by the introduction of even small quantities of food into the stomach, leeches are often of service. They should not, however, be used in the case of children unless under very exceptional circumstances, and in weakly persons the number should be restricted to two or three. If there is evidence of much congestion of the liver, or if hemorrhoids have been present, they may be applied to the anus; but usually they are best applied to the epigastric region.

Hot fomentations are of value; they should be applied continuously by means of flannel, spongio-pultice, or linseed-meal poultices. Counter-irritation by mustard-poultices, or by friction with croton oil, or, in severe cases, with tartar emetic, may be occasionally resorted to with advantage. The warm bath is also frequently of decided service.

Emetics may be administered when the presence of undigested food in the stomach is indicated by cramp-like pain, nausea, ineffectual attempts to vomit, and faintness, but care is necessary in the use of these remedies; and the stronger agents of this class, and especially tartar emetic, or even mustard, are to be avoided (see ante), as they have been known to cause great aggravation of the symptoms. The best emetic is a scruple of ipecacuanha, and the emetic action may be aided by large draughts of lukewarm water, or of infusion of chamo-
mile; but if vomiting do not occur readily, it is undesirable to repeat
the dose, a proceeding which may be followed by very injurious
results. It must be remembered that the cramp-like pain originating
in the stomach may continue in the intestines when the undigested
food has passed into them; and further, as Bamberger has remarked,
the effects and sensations attributed to the irritant may continue in
the stomach in the same manner that the impression of the presence
of a foreign body in the conjunctiva may persist long after its
removal. 1

For the condition known as "embarras gastrique," M. Martin Solon 2
has employed ipecacuanha in doses of from six to seven grains, given
three times in twenty-four hours. In most of his cases the medicine
thus given produced bilious stools and vomiting; in several instances
a single administration conducted in this manner accomplished the
cure; and in others, when a repetition of the medicine was necessary,
this was generally effected within three days. In a few cases the dis-
order was aggravated by this treatment, showing that it is only
available within certain degrees of severity of the affection; but the
presence of fever by no means contra-indicated its use.

In the milder forms of the affection, even when of some standing, 3
the utility of purgatives is considerable, and has been recognised since
the days of Hippocrates. 4 Their immediately beneficial effects were
also plainly seen in several of Beaumont's observations, 5 when the
redness and aphthous appearance of the stomach, accompanied by a
loaded tongue, frontal headache, and sallowness of skin, were relieved
by full doses of calomel and aloes.

The best remedies in these cases appear to be mercurials in purga-
tive doses. In the case of an adult and vigorous patient, calomel may
be advantageously given in doses of from three to eight grains, and
followed after some hours by a draught composed of: magn. sulph.
three drachms, magn. carb. two scruples, tinct. jalape half a drachm,
in aq. menth. pip.; or by castor oil, or the haust. senne co., or the
decoct. aloës comp. When such active effects are undesirable, the
blue pill, with compound colocynth pill and ipecacuanha, often proves
very serviceable, and it may be followed by a seidlitz draught, or by
any other moderately purgative mixture.

In the case of the acute indigestion of children beyond the period
of infancy, when there is fever and griping, or even when the latter is

1 That undigested food may, however, remain long in the stomach, and be the source
of severe pain and discomfort, is shown by two cases related by Sir T. Watson, in one of
which a mass of cascin, and in another an accumulation of smurf, were vomited, after
causing during several days severe gastric pain and disorder. (Lectures, ii. 440.)
2 Gaz. Méd. de Paris, 1836, No. xvi. I have not resorted to this plan, as I believe,
from my own experience, that an active purgation produces equally good effects with less
discomfort to the patient.
4 "Anorexia, heartburn, vertigo, and a bitter taste in the mouth of a person free
from fever, indicate the want of purging upwards and downwards." (Arb. Vi. lib. i.
sec. iv. Syd. Soc. Trans.)
5 See loc. cit. pp. 118, 182, 266.
absent, a dose of calomel and scammony, or of hyd. cum cretâ with rhubarb, followed by castor oil, sometimes proves beneficial; but children in this complaint bear purging less than adults, and frequently a dose of castor oil will, if followed for a day or two by suitable care in diet, perform all the service that can be obtained from this class of remedies.

In severer cases where there is much irritability of stomach, together with frequent vomiting and pain, purgatives by the mouth should be avoided, and they are generally inadmissible when diarrhea is present, unless there is reason to suspect that undigested food is still retained in the intestines; and the action of the bowels may be procured, if this appears necessary, by aperient emenata.

In rarer instances, when much constipation has preceded or attended the attack, and when vomiting is severe and troublesome, calomel in half-grain doses frequently repeated has been found useful in checking the latter symptom; and a similar indication has been fulfilled by the use of the mixt. magn. sulph. cum magn. carb., repeated at intervals until the bowels have acted freely. Purgatives are also the most efficient immediate remedies for the relief of the sick headache, though the state of the digestion in which they originate often requires careful attention. Mercurial or saline purgatives are the most efficient in their action, but the activity of the doses should be proportioned to the strength of the patient. Dr. Wood recommends in severe cases the combination of sulphate of magnesia with morphia.

With these exceptions, it is always undesirable to continue the repeated exhibition of purgatives, the effect of which is likely to prove as injurious as a single dose is beneficial, and is liable not only to aggravate the stomach disorder, but to cause an extension of the complaint to the mucous membrane of the duodenum and intestines, if these have not already suffered. Some caution is also necessary in the earlier stages of the febrile forms of the disorder, lest a case of typhoid should be mistaken for one of simple gastric disorder, and serious consequences be entailed on the patient by the administration of a class of remedies which, in the former complaint, must always be regarded as sources of extreme danger.

After the administration of emetics and purgatives, and in the severer cases when these are inadmissible, our main reliance must be placed on sedatives and antacids.

One of the most valuable of the former of these is cold; though it is rarely, if ever, advisable to employ it externally, but sucking small pieces of ice often affords great relief to the uneasiness of the stomach and to the vomiting. Thirst may also be quenched in this manner, but the desire of the patient to drink largely is to be restricted, as distension of the stomach is liable to maintain the tendency to vomiting.

When the vomiting is severe, opium may be administered in full doses with advantage. It is, however, more useful in the severer than in the milder forms of the disorder; and in the latter, which are more
appropriately treated by purgatives, salines, and antacids, it is seldom beneficial, and sometimes even proves the reverse.

Hydrocyanic acid is of inferior advantage in checking vomiting in this disorder, but it may be given with occasional benefit in effervescing draughts, containing an excess of alkali.

Bismuth, either in the form of the trisnitrate or subcarbonate, has a peculiarly favourable effect in all the milder forms of inflammatory action; and I have found it more beneficial than any other remedy in the gastro-intestinal catarrh of children. The bismuth should be given in doses of from three to five grains to children, and from ten to twenty grains to an adult; it may be combined with magnesia or hydrocyanic acid, or, when pain or diarrhea are present, with morphia or tinct. opii.

Carbonic acid is also a valuable agent in relieving pain and vomiting. The mode of its administration has been already alluded to.

In milder cases Vichy or Seltzer or soda water form a very valuable mode of administering antacids and salines; of the former, which is particularly useful in the latter stages of subacute inflammatory attacks, a pint, or a pint and a half, may be taken daily between the meals. The beneficial action of the alkalies is in these cases due in part to their effect in neutralizing the acidity resulting from fermentative changes caused in the food by the unhealthy secretions of the stomach, but I think it probable that some share in their efficacy is also attributable to their direct action on the mucous membrane. Bamberger speaks highly of the value of muriate of ammonia in cases where the disorder threatens to become chronic.

As a general summary of the treatment it may be stated that in the milder forms of the disease one or two doses of a brisk mercurial cathartic, followed by antacids, magnesia, bismuth, Vichy or Seltzer water, and a careful restriction in diet during the attack, will usually bring the disorder to a termination in three or four days. In the severer cases, when pain is felt after food, and vomiting is troublesome, purgatives and emetics are contra-indicated; and repose as absolute as can be obtained for the patient and for the organ, together with opium, ice internally, or small quantities of effervescent drinks, and leeching, fomentations, or counter-irritation to the epigastrium, are the indications principally to be relied on for obtaining a cure.

A weakened state of the digestion, entailing a liability to fresh attacks, often continues after the acuter symptoms have subsided; it is attended with a feeling of languor and of inability for active exertion, and not unfrequently with flatulence or occasional heartburn, or with some other of the symptoms of atonic dyspepsia. This state requires great care in treatment, and the use of the so-called bitter tonics demands especial caution, as their untimely use will often perpetuate a chronic form of subacute inflammatory action.

The general rules laid down for the treatment of atonic dyspepsia are those most applicable in these cases; and attention to diet is to be pursued with additional caution, which is to be especially
extended to vegetables and fruit. Exercise should be moderate, and should not be pushed beyond a degree sufficient to cause a slight and healthy feeling of fatigue. Chills should be carefully avoided; for patients in this condition are as liable to "take cold" in the stomach as others, in whom the respiratory system is weakened, are to attacks of bronchitis. Alcoholic stimulants are only to be used in great moderation—dry sherry (the Manzanilla or Amontillado being the best), or weak brandy and water, or claret and water, are the most suitable forms for their administration; malt liquors, and also the use of coffee, are to be decidedly forbidden. If all signs of irritation have disappeared, while those of atony continue, and if the deficiency in the appetite indicates the use of bitters, calumba and nux vomica are those most applicable; these may generally be advantageously combined with the mineral acids, and should be given immediately before food is taken.

Pepsine, also, often proves very serviceable at this stage.

If anemia be present, the milder ferruginous preparations are to be employed in the manner indicated under the head of Atonic Dyspepsia.

Care and patience are at all times necessary in cases of this description. The tendency is to a cure, if it be not interfered with by undue haste on the part of the patient to regain strength, by taking food in excess of the digestive powers of the stomach, or by the use of stimulants beyond a degree which the weakened tissues are able to support without their normal action being perverted to inflammatory irritation.

Purgatives, which the sluggish condition of the bowels may sometimes appear to render necessary, are also to be used with great care. Aloes is usually the best form that can be selected; but the use of enemata is to be preferred. In children, small doses of rhubarb and soda, or of the domestic Gregory's powder, are often decidedly advantageous; or friction with aloes may be employed on the surface of the abdomen.

In infants, small quantities of magnesia will often answer all indications in this respect; but in them the tendency to diarrhoea is more marked than in adults, and purgatives are seldom necessary.

In older children and in adults, the action of the bowels is often facilitated, and irritability of the gastro-intestinal membrane greatly relieved, by wearing over the abdomen, either during the day or night, a compress wrung out of warm or cold water, and protected by a piece of mackintosh. It should be changed three or four times in the twenty-four hours.

Change of air and scene, as spoken of under the head of Atonic Dyspepsia, is sometimes necessary in weakly patients to complete a cure.
V.—**CHRONIC GASTRITIS.**—CHRONIC CATARRH OF THE STOMACH.

**SYNONYMS.**—Chronic Inflammatory Dyspepsia, Morbid Sensibility of the Stomach (Johnson); Gastrite Chronique, Fr.; Chronisches Magen Catarrh, Germ.

**DEFINITION.**—A disorder of digestion, the symptoms of which consist in the imperfect assimilation of food, associated with physical and moral depression, with irregular appetite, thirst, and slight degrees of pyrexia, and with impairment of the general nutrition, attended in some cases by gastric pain, by the vomiting of mucus, and by various alterations in the urine, and which depend on chronic inflammatory conditions of the stomach, revealed by congestion, pigmentation, and thickening of the mucous membrane, and by atrophy and degeneration of its secretory glands.

This disease embraces a large number of the cases of obstinate chronic dyspepsia, and includes, in the author's opinion, many of the disorders which have been described as irritative dyspepsia, and even some which have been ranked among the nervous disorders, and especially those forms which have been regarded as resulting from "morbid sensibility"—a condition which in mucous tissues is much more commonly the result of minor degrees of inflammatory action than of mere derangements of innervation. Confusion has also been introduced into the nosology of this disorder by the inclusion under this title of cases of ulcer and cancer,\(^1\) and especially of the former.

**THE ÄETIOLOGY** of this affection is somewhat complex, since the disorder may either exist *ab origine* in a subacute form, perpetuated by the persistence of its exciting causes, or may remain as an effect of an acute attack, which has weakened the nutrition of the mucous membrane, and has thus induced a liability to minor degrees of inflammatory action from slight causes. It is therefore difficult logically to define in all cases the limits between the predisposing and the exciting causes, since many of each class act apparently in both directions.

The disease appears to be to a certain degree hereditary, but no special aetiological influences can be attributed either to sex or age, as it is common at all periods of life.

The impaired condition of the digestive powers which has been described under the head of Atonic Dyspepsia induces liability to inflammatory disorders of the stomach, and hence the causes of this state may all act as indirect predisposing causes of the irritative forms, both of the acute and of the chronic kind.

Among the other constitutional diseases which appear to involve a

---

\(^1\) Cf. Andral, Clin. Méd.
special liability to this affection—though often acting apparently in
diverse manners—may be mentioned scrofula, phthisis, gout, albu-
minuria, and diseases tending to disturb the portal or abdominal
circulation, such as emphysema, heart disease, and, à fortiori, cirrhosis
of the liver, or other conditions affecting the circulation through this
organ. The following table exhibits the principal diseases with
which I have found either acute or chronic catarrh in 100 stomachs
examined:

One remarkable fact which appears from this table, especially in
the contrast between cases of recent and chronic catarrh, is the
greater proportionate frequency with which the former is associated
with acute, and the latter with chronic, inflammatory affections of
other organs; and it would seem as if the same exciting cause not
unfrequently sufficed to produce similar changes in the ultimate
structures of many organs simultaneously.
The tendency of diseases obstructing the venous circulation to induce chronic catarrhal conditions of the stomach is also well illustrated in this table; but the remarkable frequency with which they are associated with phthisis is especially apparent, having been present in 28 per cent. of the whole number, or in sixteen out of thirty-one, or nearly one-half, of the tubercular cases examined.¹

Of the more direct exciting causes, among the most frequent must be placed either an habitual excess in eating, or a constant use of food that disagrees; especially by persons whose general health and digestive power are below the healthy standard: by this means a series of minor attacks of indigestion of an irritative type are excited, which at times alternate with acuter forms of "embarras gastrique," from which such patients are continually liable to suffer.²

It cannot be too strongly insisted on, that the tendency of undigested food is always to give rise to gastro-intestinal irritation, whether the cause of the indigestion reside in the stomach, or in the quality or excessive amount of the food or drink, or in some of the other accidental conditions mentioned among the general causes of dyspepsia,—of these deficient insalivation or imperfect mastication, or the habits of mental or physical work after meals, are among the most frequent.

The habitual use of spirits, particularly when undiluted, or to any amount that can be considered excessive, is also an almost unerring cause, when long continued, of chronic inflammatory changes in the stomach; and it is seldom in cases of this nature that some of the post-mortem changes hereafter to be mentioned cannot be discerned.³

Chronic or subacute catarrh of the stomach is also a very frequent accompaniment of cancer and ulcer of this organ, as well as of pyloric obstruction. The question of the mode of its causation in the two former of these diseases is one of no little difficulty, but it is probably to its agency that many of the derangements of digestion observed in their course are attributable.

Medicinal causes deserve also some consideration, and especially

¹ The author's more recent observations, though not capable (from peculiar circumstances) of being framed statistically, have fully confirmed his opinion of the atiological influence in this direction of these classes of disease; and he has been increasingly struck with the frequency of the co-existence of the anatomical conditions to be described, as found in chronic catarrh, with cirrhosis of the liver and with granular conditions of the kidney, to which they bear the strongest resemblance. Dr. H. Jones's observations also give some support to this view, for, in twenty-three cases of catarrh of the stomach, he found tubercles in four and disease of the lungs in eleven more, while in eight there was disease of the kidneys, and in three disease of the heart.

² Broussais (Lec. Phleg. Gastriques, p. 180) says that the causes which in adult age perpetuate a chronic irritation would, in the earlier periods of life, have produced an acute attack.

³ The average ratio, in persons who have indulged in these excesses, of deaths from the digestive organs (including disease of the liver) to deaths from all causes, according to Neilson's researches, amounts to 12:47. ("Vital Statistics," quoted by Parkes on Hygiène, p. 299.) I believe that the amount of injury to the stomach is much underrated, since changes in this organ often escape observation, and are rarely directly the cause of death.
the abuse of stimulants and tonics or purgatives in many of the forms of atonic dyspepsia; nor can other remedies be absolved from the onus of having occasionally produced these effects, which have been attributed to the prolonged use of arsenic and bichloride of mercury, and occasionally of cubebs and copaiva.

There are some cases of syphilis recorded, accompanied by symptoms closely resembling those characterising this group of diseases, and which have been cured by the administration of mercury. The evidence of their nature is incomplete, but, pending their complete elucidation, I am inclined to believe that, judging of the effects of this poison on other tissues, such disorders are most suitably classified among the inflammatory affections of the stomach.

Lastly may be mentioned, mechanical irritants of all kinds.1

The Symptoms of this disorder are primarily those of indigestion of an aggravated kind, but they are often varied, and very irregular in their course; nor are they always united in one case, some being at times more prominent than others. It is of this class especially that the remark made with regard to the general symptoms of indigestion will be found to be true, that the condition may often be revealed by the general state of the system, or by impairment in the functions of some other organ, rather than by symptoms appreciable by the patient himself, as truly proceeding from the deranged stomach.

In many cases there are at times intervals of almost complete immunity from apparent dyspepsia, but these are seldom complete, and are speedily followed, often with no apparent cause, by returns of the old symptoms, and with exacerbations of an acuter kind, after the slightest indiscretion in diet; and this irregularity is of no small value in distinguishing the nature of the complaint, having its parallel in most of the chronic inflammatory affections of other mucous membranes.

Those referable to the stomach are a sense of weight, oppression,2 distress, or undefined uneasiness at the epigastrium, ensuing after meals, and often associated with distension from flatulence, which sometimes may be very considerable; a sense of tightness and constriction at the sternum, or a feeling of fulness in the pharynx and esophagus; and in other cases an uneasy, ill-defined sensation of discomfort is felt in the dorsal region between the scapulae, though rarely also in this situation amounting to the acuter pain met with in ulcer and cancer. The sensations complained of generally commence within half an hour to an hour after taking food, and continue more or less during the whole period of digestion. Other discomforts follow at a later period, such as intestinal flatulence, and

1 See a case, of pins swallowed by an hysterical woman. (John Marshall, Med.-Chir. Trans. xxxv.)
2 Barre of the French writers, described "as if a bar were pressed across the epigastrium, or base of the chest."
borborygmi, together with an increased sense of distension and oppression, especially felt in the right hypochondriac region. Sometimes these uneasy sensations, when accompanied by acidity, are relieved by taking more food; but this alleviation is frequently only temporary, and is followed by an increase of the original discomfort.

The ingestion of food is rarely, if ever, a cause of immediate pain; and this is not, indeed, a prominent or (with any severity) a frequent symptom, though it may occasionally arise if much mucus is secreted, or when flatulence is present.

Tenderness on pressure is not usually a marked symptom, though some degree of it often exists. Heartburn and acidity are often very annoying, but they are by no means constant.

Nausea, to a certain degree, is not unfrequent, but it is seldom distinctly felt; and vomiting is rare, except in certain special forms, associated with either albuminuria, congestion, the dyspepsia from drink, and occasionally with phthisis.

The appetite presents considerable variations. It is capricious, and generally it is diminished, though not, as a rule, to a marked degree. Eating is, however, soon followed by a sense of satiety; and the feeling of discomfort and fulness at the stomach which often ensues, even during a meal, serves at once to check the desire for food, though if this be neglected, and a full meal taken, the symptoms are usually increased in severity. In other instances there is the same sense of sinking, and of craving for food, which is observed in some of the neuroses, and which must in these cases be considered as a perverted sensation arising from the condition of gastric irritation; though it should be borne in mind that nervous erethism may at times complicate this complaint, and introduce much complexity among the symptoms observed.

Thirst is a very prominent and distinctive symptom, and it is hardly ever absent in cases of inflammatory irritation of the stomach, whether this be acute or chronic. It exists during meals, but is most marked in the intervals, when the patients have an extreme craving for fluid; and this is particularly felt in the evening, if the chief meal has been a late dinner. The feeling is not only one of thirst, but a sense of languor, oppression, exhaustion, or internal heat is often combined with it, which is relieved by drinking, and especially by cold fluids; but in some cases even these give distress, and warm drinks, especially tea, are eagerly taken, though often in the latter case only to be followed by increased discomfort, acidity, and flatulence.

The breath is often heavy and offensive. There is very frequently a bad taste in the mouth, which is ordinarily most marked on first rising in the morning. The gums are spongy, red, swollen, often retracted from the teeth, and inclined to bleed, and the saliva and buccal mucus are occasionally acid. An excessive flow of saliva is not uncommon, and is particularly observable at night, when it may escape from the mouth during sleep, wetting the pillow. The lips tend to become dry and cracked, and the fauces are liable to erythematous
inflammation, with slight superficial ulcerations. The pharynx also
may be the seat of a granular inflammation, associated with excessive
secretion of a tenacious mucus, which is a source of great anno-
ynce and discomfort to the patient.

The conditions of the tongue present some variations: but as these
are valuable aids to diagnosis, they deserve to be especially dwelt upon.

(a) If associated with distinct atony, the tongue may be broad,
somewhat pale, and flabby, but the papillæ generally are enlarged
—this being most apparent in the fungiform papillæ on the tip and
edges, which are also redder than natural, and there is a thin white
fur over the surface. Sometimes, however, this fur may be present
when the papillæ, though enlarged, are pale.

(b) In the more distinctly irritative forms, and especially in children
who have any signs of scrofula, and in phthisical adults, the whole
organ is redder than natural, and may be of a bright florid colour,
and even raw-looking; it is often pointed at the tip, which, together
with the sides, presents an extreme degree of injection, and the papillæ
stand out as vivid red points. There may be at the same time a
coating of variable thickness along the dorsum. This form is fre-
cently associated with aphthæ, especially at the tip, and sometimes
on the inside of the lips; or with painful spots on the tongue, which
are found on close examination to be papillæ slightly abraded.

(c) In older persons, and particularly in those in whom the dys-
pepsia is the result of excessive or hurried eating, the tongue, while
presenting some degree of enlargement and redness of the papillæ at
the tip and edges, is often uniformly covered throughout the greater
part of its extent with a thicker fur, sometimes whitish, and occa-
sionally of a browner tint, which more resembles the coating attending
the acuter attacks, and which patients recognise as a symptom of
"biliousness."

(d) Lastly, it must be mentioned, that in cases which I cannot but
regard, as far as my experience extends, as being exceptional, though
more common where the catarrh of the stomach is secondary to local
causes of congestion from venous obstruction, the tongue may present
very little deviation from the natural condition, though occasionally
even in these transitory formations of a white fur on the dorsum may
be observed on repeated examinations.

Some of the intestinal symptoms have been already alluded to. In
addition it must, however, be noted, that constipation is often obsti-
nate; it is frequently associated with much uneasiness in the rectum,
and it greatly increases the general feelings of oppression, malaise, and
langor. The stools may be dry and scybalous, and are not unfre-
quently coated with a considerable amount of tenacious mucus, which
may form casts of portions of the intestinal canal. Occasionally they
are passed with tenesmus and straining; sometimes they present
thin flattened bands; and they are usually accompanied or preceded
by the escape of flatus. They are generally pale, both in this state
and in another occasionally met with, when the constipation is less
DISEASES OF THE STOMACH.

marked, and when one or two large, pultaceous, often offensive, and sometimes frothy, motions, containing considerable quantities of undigested food, are passed in the day—when there are often gripping pains in the abdomen, and a liability to severer attacks of colic. In other cases the two conditions alternate, or slight causes may give rise to transitory attacks of diarrhea, which may afford temporary relief, but are commonly followed by an aggravation of the intestinal flatulence and of the general discomfort, and are often attended with increased signs of irritation on the tongue and with the production of aphthae, as before described.

Piles are a not uncommon complication of this state, even when evident disease of the liver is absent.

The cutaneous surface shows various indications of the perverted general nutrition of the body. It is often dry and harsh, sallow, earthy, and wrinkled; and at times, after slight indiscretions of diet or without assignable cause, patients are liable to suffer from eczematous or impetiginous eruptions, which may be followed by a perceptible alleviation of the symptoms. Children are more liable to suffer from these, and occasionally from herpetic eruptions, than adults; but gouty patients, and those who drink excessively of malt liquors, are occasionally subject to them. A vinous tint on the malar bones and nose is also by some writers attributed to the disturbance of the stomach.

The hair tends to become dry, harsh, and prematurely grey; sometimes it is lost in considerable quantities when acuter exacerbations supervene. The nails are often furrowed, and have a tendency to split. In children who suffer much from irritative dyspepsia during the second dentition, the teeth are often irregular, with thin enamel, and are crenated at the edge, while the anterior and, to a less degree, the posterior surface are marked by vertical depressions or sulci. In adults the teeth suffer from premature caries, often erroneously attributed to the use of mineral acids given for the cure of the complaint, but more commonly due to impaired general nutrition, and especially to the spongy condition of the gums and to their retraction above the enamel.

1 A case of this kind lately came under my notice, of a young lady whose father is liable to gout, and who had for years been liable to an aggravated form of irritative dyspepsia, but whose symptoms almost entirely disappeared for many months since the eruption of an eczematous rash on her face. Trouseau (Clin. Méd. ii. 1862, p. 280) has noticed that in dyspeptic patients who resort to sea-bathing a febrile condition, followed by urticaria, frequently results, and that the eruption on the skin is followed by a great relief to the symptoms of the stomach. Allusion has been already made to the occasional concurrence of this disorder with some of the forms of acute indigestion, and a somewhat similar instance is also mentioned by Schmidtmann (loc. cit. iii. 225): "Novi malieven in qua herpes faciei cum cardialgia alternabat; extante in facie herpes a cardialgia vacabat; eo disparente, extemplo duris torquetabatur ventriculi doloribus."

2 Rayer, Dict. de Méd. x. 156; Chomel, ib. x. 92.

3 This condition of teeth is very common among children to whom "grey powder" has been administered at the time of the second dentition; but I have frequently observed it, independently of this cause, where there has been much dyspeptic disturbance at this period. In a third class of cases it is hereditary, appearing when the digestion is good; but it is not unfrequently associated with scrofula.
Emaciation is almost constantly observed when this disorder has persisted for any length of time, though it is not early in its appearance, unless the patient has been previously out of health, or the disease is severe; but a gradual loss of flesh and strength is an almost constant symptom, and one that should, in the absence of other signs of disease, cause a special attention to be directed to the state of the digestive organs.

Coldness of the extremities is a very common symptom, and it is not unfrequently attended with flushing of the face and oppression of the head. Patients of this class are almost always chilly. They are liable to slight rigors and to suffer much from changes of temperature, which are often followed by an aggravation of their sufferings.

Febrile reaction of a slight type, preceded by rigor and malaise, is very common. It often appears to be directly associated with the taking of food, or of alcoholic stimulants, but in other cases it seems to have a special tendency to exacerbation in the evening; sometimes returning with such regularity as to have given rise to the suspicion of a malarial cause, and to have led to the ineffectual use of quinine.\(^1\) The skin becomes hot and dry, especially in the feet and hands; but in other cases these may be cold, while a great sense of heat is complained of in the trunk and head. It occasionally occurs at night, and then is often followed by copious perspirations during sleep.\(^2\)

There may be at times an icteric tint of the conjunctivæ, but this is not observed with any considerable frequency. Slight attacks of ocular conjunctivitis, sometimes attended with phlyctenæ, are by no means uncommon.

Slight catarrhal affections of the air-passages are also not unfrequent. Those of the fauces and pharynx have been already alluded to; but the same condition may invade the larynx, giving rise in some cases to injection, with relaxation of the vocal cords, and thus causing dry cough, or hoarseness, and huskiness of the voice; or the affection may extend deeper, and be the source of a muco-purulent secretion, which is often aggravated during the febrile accessions which occur after meals, and especially after wine has been taken, and may give rise to cough coming on at these periods.

Dyspnœa, and a desire to sigh, are very frequently complained of. They are sympathetic symptoms common to all forms of indigestion, but are very marked in the variety now under consideration.

A very interesting and important question connected with this subject is the connexion of these disorders to the causation of phthisis.

By some authors\(^3\) disturbance of the digestion has been considered to be an immediate cause of the development of pulmonary

---

1 Chomel, Des Dyspepsies, p. 79.
2 It may be well here to recall the aphorism of Hippocrates in relation to the causation of many of these forms, which has been already alluded to: "A copious sweat after sleep, occurring without any manifest cause, indicates that the body is using too much food." (Aph. 41, sec. iv.)
3 Wilson Philip, Mr. Hutchinson (Med. Times and Gazette, 1855). The dyspepsia
DISEASES OF THE STOMACH.

875

tubercle; while by others the relation of the two conditions has been considered as accidental; or it has been held that the irritative dyspepsia so often observed in phthisis is secondary to the tuberculizing process in the lung.

It would appear, however, to the author that in cases where long-continued irritative dyspepsia has preceded disease of the lung, that the latter has required for its production some other exciting or predisposing causes than the simple impairment of nutrition produced by the mal-assimilation of the food. In the majority of instances where they co-exist both the gastric and pulmonary disturbances have either both appeared to be due to an unhealthy constitutional condition, and have been developed and advanced almost pari passu, each accession of pulmonary disorder with pyrexial disturbance being associated with a fresh attack of gastric catarrh, which has tended to become chronic; or the derangement in the stomach has been secondary to that in the lung, caused either by pyrexial conditions, by impairment of the general health, or possibly by reflex irritation.

The urine, in most of the chronic inflammatory affections of the stomach, is more constantly affected, in various ways, than in the other forms of disturbance of digestion before noted. The most common of the changes presented are the deposits of urates, earthy phosphates, and oxalates. None of them are peculiar to this form, and urine of high specific gravity, and characterised by the deposit of urates, is almost invariable in the acuter stages of inflammatory dyspepsia.

Earthy phosphates with urine sometimes of a high, and sometimes of a low, specific gravity, and often alkaline and cloudy on emission, are also common. The specific gravity depends, in some measure, on the amount of fluid taken with the meal preceding the period at which the urine is passed; and thus it is commonly low in the morning after breakfast, and generally higher in the evening, when the exertions of the day and the food taken have probably increased the amount of urea. By some authors this condition of cloudy alkaline urine, which often becomes iridescent on standing, has been referred to duodenal indigestion,1 the idea having probably arisen from the concurrence of the deposit in the urine with the period at which the food passes into the intestines, and with the aggravation of the symptoms of malaise and flatulence which often occur at that time. The author is inclined to believe that the alkalescence of the urine in these cases may be in part due to the defective secretion of the liver and pancreas; of the former of these we have frequent evidence in the pale, clayey stools, and also some presumptive proof in the great increase of flatulence which occurs in the intestines. The fact that these deposits often alternate with urates, and sometimes with oxalates, lends a further support to this view; since the latter seem

preceding phthisis has been attributed by Dr. Hughes Bennett and Mr. Hutchinson to a dislike to and mal-assimilation of fatty substances.

to be invariably associated with faulty assimilation or metamorphosis of protein and saccharine matters, and may probably depend on the abnormal condition in which these enter the blood after the imperfect intestinal digestion caused by the deficiency in supply of those secretions.

The deposit of urates is often associated with the febrile heat complained of after meals, but the same symptom has been noted in connexion with both oxalic and phosphatic deposits.

The nervous system participates markedly in the general disturbance.

Languor, lassitude, pains in the trunk and limbs—the latter sometimes dull and aching, sometimes, when in the scapular region, severe and lancinating, at others directly affecting the muscles, and simulating conditions of chronic rheumatism; a feeling of inability for exertion, especially marked after meals, and often felt on rising in the morning; irritability or excitation of temper, intellectual depression, loss of judgment and of the reasoning powers, and of memory, characterise this state. Hypochondriasis occurs also more commonly in connexion with this condition than with almost any other form of dyspepsia. Fear, timidity, anxiety, despondency to such a degree that, "in a merchant surrounded by affluence, apprehensions of impending beggary often embitter the moments that are free from the excitement of business; in the mechanic, unfounded ideas of immediate loss of employment, and visions of the interior of a workhouse, are generally present."

Headache and a feeling of tension are frequently present; but the sick-headache is not so common in advanced forms of the disease, unless under the supervention of acute attacks of indigestion, as in the simple atonic or acute forms, the feeling being generally rather one of fulness, or of dull pressure, in the occipital or frontal regions. Vertigo is occasionally met with, especially when irritation has supervened on the atonic form; but with this exception it is, comparatively speaking, rare in this variety.

The expression is anxious and careworn, and in conjunction with the emaciation and sallow tint of skin so commonly present, gives to the individual a look of premature age.

Extreme degrees of sleeplessness are very common; or when, after hours of restlessness, sleep is at length attained, it is disturbed by dreams and nightmare, and is often associated with nocturnal emissions.

The heart's action is often irregular, and easily excited to painful

2 Golding Bird, loc. cit. pp. 244, 291. Phosphatic urine and oxaluria may, indeed, occasionally occur when the condition is one of simple atony or neurosis, but it is probable that when they are persistent, or of any severity, some conditions of organic irritation, tending still further to impair the digestive power, are almost invariably present.
3 Ibid. p. 308. This mental state, so graphically described by Dr. Bird as occurring in connexion with phosphatic urine, may be found in conditions of irritative dyspepsia, when these changes in the urine are not at the time present.
4 Chomel.
palpitation on slight exertion, conjoined with which there may be at times some irregularity of action. The pulse is accelerated during the febrile movement following digestion, when it is full and compressible; at other times it becomes weak and slow, in proportion as the patient loses strength by the continuance of the dyspepsia.

In the foregoing sketch a description has been given of the leading symptoms which correspond to cases where the anatomical characters hereafter to be described are found; but the whole of this group does not invariably appear simultaneously. The course of the disorder is also modified by the various aetiological conditions under which it occurs bringing certain symptoms into greater prominence than others, and also by its occasional complication with some of the neuroses, to which reference has previously been made, and which are among the chief sources of obscurity in the diagnosis of the severe forms of both affections.

The most typical examples of the disease, as affecting both the digestive organs and the nervous system, are those where irritative dyspepsia has supervened in a debilitated constitution, and has been preceded by the symptoms of atonic dyspepsia. They are yet more marked if in such a constitution there is any taint of hereditary gout, which may not have been revealed by a distinct attack, but where the emaciation, weakness, and hypochondriasis are familiar to all who have had opportunities for observing these complaints.

In the scrofulous forms in children, the attention of the parents may be directed only to the pallor, weakness, and gradually progressing emaciation of the patient, and the evil is constantly aggravated through ill-advised attempts to improve the nutrition by forcing increased nourishment on a stomach already incapable of digesting the normal amount. Phthisical dyspepsia, on the other hand, is often painfully complicated by the diarrhoea proceeding from ulcers in the intestines, but which possibly in some degree aids in preventing the oppression and hypochondriasis which so frequently attend the constipation presented by some of the other varieties.

There yet remains a group of cases where vomiting constitutes a more prominent symptom than in those which have hitherto been passed in review, and where there occurs a profuse secretion of mucus, and which stand in the same relation to the forms in which this is not so apparent as a bronchorrhoea, or leucorrhea, or nasal catarrh occupy to the drier forms of inflammation of the mucous membrane from which those fluxes may proceed. The cases where gastorrhoea is a prominent symptom are ordinarily those of congestion of the stomach from pulmonary, cardiac, or hepatic disease, and of dyspepsia in habitual drunkards, in which the last-named cause of congestion often, I believe, plays a prominent part; and to these must be added many cases of albuminuria.¹

¹ Bernard's experiment has shown that after extirpation of the kidneys a continuous secretion takes place from the stomach without any necessary alteration of its mucous membrane; but in cases of longer duration of Bright's disease pathological observations
Sometimes the vomiting of albuminuria occurs on first rising in the morning, when it is occasionally relieved by food: under these circumstances it is possible that it is of cerebral origin, and is caused by the disturbance of the nervous centres through the poisoning of the blood; but in a large class it takes place within half an hour to an hour after food has been taken. Pain, though sometimes present, and occasionally severe, is, however, but rarely complained of; and though much acidity is sometimes present, the reaction of the vomited matters may be at other times alkaline: but the cause of this difference has not, as far as I am aware, been made the subject of special observation.

In the dyspepsia of drunkards the vomiting of mucus is often one of the most prominent symptoms. It usually occurs in the morning, and is easily excited by slight stimuli. During the rest of the day there may be comparatively little disorder in the stomach, though acidity and flatulence are sometimes present, and the appetite is often greatly impaired. In other cases a painful sense of sinking is experienced at the epigastrium, together with a craving for the accustomed stimulant, which too often replaces all desire for food. The disturbances arising from this indulgence affecting the nervous system, the ascites and sallow skin, the icteric tint of the conjunctive and the signs of cirrhosis, belong more properly to other sections of clinical medicine and pathology.

In some cases, however, a symptom common to it and to other forms of congestion, occurs, viz. hæmatemesis, which may occasionally be profuse, and return with such frequency as to threaten life, and to reduce the patient to an extreme degree of anæmia. The severer forms are most frequently associated with cirrhosis of the liver, causing obstruction of the portal vein; but minor degrees of the affection often appear in conjunction with disease of the kidney. It is very probable, judging from the results of post-mortem observation, that haemorrhage not unfrequently takes place without being disclosed by the blood vomited, the matters brought up being chiefly alkaline mucus (sometimes considerable in amount, and which may here and there only have a coffee-ground tint), bile, or altered food. Sarcinae are occasionally found in the vomited matters of the whole of this group of cases.

Pain in these cases is a symptom which is variable in the frequency of its occurrence; it is often complained of after each meal, but is seldom, if ever, of marked severity. Flatulence is almost constant. Acidity is common, but is not comparatively so frequent. The

have convinced me that the stomach seldom fails to exhibit signs of subacute inflammatory action (see also Rayer, Mal. des Reins, ii. 347). These anatomical changes are probably due to the continuance of the unnatural secretions.

1 Christison, Granular Degeneration of the Kidneys, p. 96.
2 See Handfield Jones, "Stomach," p. 91, where grumous blood was found in the stomach after death, none having been vomited during life. I have met with several such cases.
3 For the more special description of the nature of the matters ejected the reader is referred to the chapter on Vomiting as a symptom.
progress of the disorder, in other respects, depends much on the complications with which it is connected.

Pathology.—The changes which accompany the more marked forms of this disorder are tolerably characteristic. Many of them are apparent to the naked eye; others are only disclosed by microscopic examination. The most distinctive of these are alterations in the vascularity of the mucous membrane, changes in its colour, increase in its thickness and resistance, occasional increase of the lymphatic elements in the intertubular tissue, and various forms of degeneration of the glandular and other structures.

The degree of post-mortem vascularity, however, presents the same difficulties as a criterion as were mentioned in the description of the appearances observed in the acuter form; and even congestion from obstruction, sufficient to give rise to hæmorrhage, may leave no distinct traces in the mucous membrane after death. Often, however, the long continuance of distension of the vessels produces an amount of dilatation, which, when combined, as the affection frequently is, with exacerbations of an acuter kind, gives greater post-mortem evidence of hyperæmia than is found in the cases when inflammatory action has been of shorter duration.

Where much congestion has been present, the hæmorrhagic erosions previously alluded to are also very common,¹ and they depend on an extravasation of blood in the substance of the mucous membrane, which results from capillary rupture. They seldom exceed two or three lines in diameter, and they are generally superficial; but they may be sometimes seen extending through the whole depth of the mucous membrane. In some places the tissue may be seen still infiltrated in patches, where the blood has been effused, without detachment of the softened surface; but in others there are seen little pits or depressions with a blackened base, and with sides still infiltrated with blood, which, on microscopic examination, is found to occupy the tubules, staining their epithelial contents. They may possibly in some cases be the source of pain, but when small they appear to have little other pathological significance.² Vascularity may be found in any part of the mucous membrane; but changes of colour and thickenings of the tissue are more common in the pyloric portion, as also are many changes in the glandular tissue hereafter to be described.

The most characteristic change in colour is an ash-grey pigmentation, which, when closely examined, is found to depend on minute

¹ Willigk, Prager Viertel Jahreschrift, vol. li., gives their frequency as 1-8 per cent. of all the bodies examined. I know of no statistics mentioning their relative frequency to causes likely to produce these extravasations.

² Larger extravasations appear, however, sometimes to serve as the origin of the chronic ulcer of the stomach.

³ Andral described a milky-white colour of the membrane as characteristic of chronic inflammation. There is generally a certain degree of opacity induced in this condition; but unless an acute affection should have supervened before death, I do not think that it is common in this disease, except in spots resulting from fatty degeneration of the glands,
black specks scattered closely over the surface of the membrane. It is generally most marked in the pyloric half of the stomach, though traces of it may occasionally be met with near the cardia. When examined with the microscope, these spots are found to depend on pigment derived by imbibition from the haematin of the blood, and deposited in a minutely granular form in the cells of the connective tissue between the tubes, and sometimes in the epithelial contents of the latter. It is most commonly met with when mechanical causes of congestion have co-existed with catarrhal changes, and requires probably, as an antecedent condition for its production, the rupture of capillaries in the superficial layers of the membrane; and it is very commonly associated with similar changes in other parts of the intestinal tract. But though its presence is a valuable indication of the nature of the causes in which it has had its origin, its absence by no means excludes the diagnosis of past inflammatory action, of which other and independent evidence can be found in the consistence of the membrane and changes in the glands, and which, though often associated with pigmentation, can also frequently be discovered when this is absent.

Thickening and induration of tissue is an almost uniform result of chronic inflammatory action in the mucous membrane of the stomach. This may at times acquire an extreme degree of firmness and resistance, tearing with great difficulty, and being capable of being stripped from the submucous tissue in large pieces. There may be sometimes a slight degree of softening of the surface, when recent inflammation has supervened on the chronic form, but it does not usually extend sufficiently deeply to affect the general characters of induration which are so characteristic of this state. These changes depend on an increase of the interstitial tissue between the glands, which is often associated with atrophy of the latter; but it may also exist when this secondary change has not ensued.

Enlargement of the solitary glands, together with an increase of the lymphatic interstitial growths between them, is common, though not constant, in this form.

The mammillation considered by Louis as a constant sign of inflammatory action, and coincident usually with the other appearances now described, has given rise to considerable diversity of opinion among pathologists regarding its origin. It is almost invariably found in the neighbourhood of the pylorus rather than in that of the cardia, where only very slight traces of it can be discovered. The appearance described by Louis, of irregular prominences more or less rounded, of two or three lines in diameter, separated by sulci, and resembling presentsly to be noticed. In some of his cases the appearances described are those of the cicatrices of ulcers. (See Clin. Méd. ii. 153, 154.)

1 This was noticed by Broussais (Lec. Phleg. Gastriques, 1823, p. 105), who gave it the term "coriaceous." I have myself found the membrane almost as tough and resisting as leather in more than one case.

3 See Hodgkin, Morbid Anatomy of Mucous Membrane, ii. 280.
the granulations upon wounds, when found in a healthy stomach most commonly results from the contraction of the muscular layer shown by Brücke\(^1\) to exist around the bases of the secreting glands.\(^2\) A very similar appearance may, however, be produced by hypertrophy and distension of the gland tubes with the products of secretion, forming, together with the thickened interstitial tissue,\(^4\) small granulations,\(^5\) which are often rendered increasingly apparent by the atrophy of adjacent structures, and which thus present a counterpart in the stomach to the conditions observed in the granular kidney and in cirrhosis of the liver.

Coincidently with the above, other changes take place in the secretory structures which must necessarily tend greatly to impair their functional activity. They may be briefly summed up as consisting in fatty degeneration of the glandular epithelium, associated with thickening of the membrana limitans, and finally tending to changes in shape or to atrophy of the glands.

Fatty degeneration of the glands generally occurs in the stomach, as in other glandular organs, in scattered groups, of one or two lines in diameter, giving the appearance of small dead white spots imbedded in the mucous membrane. When microscopically examined, the epithelium of the tubes is found either fatty degenerated or the cells have entirely disappeared, and the contents of the tubules consist of nothing but free fat granules. The tubes are often irregularly narrowed and puckered, and thickening of the membrana limitans may not unfrequently be observed around their bases;\(^6\) and these changes lead finally to the obstruction of the

\(^1\) Bericht der Wiener Akad. 1851.

\(^2\) If sections are made of membranes in this state, after hardening in chromic acid, it will be seen that the depressions consist of a group of from ten to twenty glands dragged down, as it were, below the surface of the others, but perfectly healthy in every other respect, and with no sign of atrophy of the glands, or of alteration of the surface.

\(^3\) Andral, Clin. Méd. ii. 76.

\(^4\) It is, I think, possible that the mere thickening of the interstitial tissue, especially when this is induced by a rapid increase of lymphatic growth, may in some instances alone suffice to induce this appearance.

\(^5\) Polypoid growths of various sizes may form, especially in the pyloric region, which are due to the same cause (Rokitansky, Path. Anat. 1861. iii. 154, 155). They are not necessarily associated, however, with inflammation, though they are often very marked around cancers of the stomach. See also Andral, Prec. Path. Anat. ii. 50, 53, Clin. Méd. ii. 60. A complete monograph on this subject has been published by Ebstein, Reichert, and Du Bois Reymond's Archiv, 1864.

\(^6\) This, which is an inflammatory change, met with also occasionally in the acuter forms, requires to be distinguished from a fallacious appearance of the same kind which sometimes follows the addition of liq. potasses or liq. soda to a section of a healthy mucous membrane. The pathological change may be recognised without reagents, or in glycerine, which does not produce this effect.
tubes at some part of their length, and to the formation of cysts from the distension of the portion below the obstruction with the products of secretion.¹

Spots of fatty degeneration are also found, affecting both the gland-tubes and interstitial tissue, which sometimes extend through the whole thickness of the membrane, and are in some cases attended with a similar degeneration both of the capillaries and of the smaller arteries leading to the spot affected. These changes sometimes lead to a breaking down of the tissue, which resembles that seen in the superficial fatty degeneration of the lining membrane of the aorta, to which Prof. Virchow has applied the name of "fatty usur."²

Cases of chronic gastro-intestinal catarrh are sometimes found associated with the lardaceous, waxy, or amyloid degeneration; which, however, usually only occurs in these viscera when other tissues of the body, the liver, spleen, kidneys, and mesenteric glands, are largely affected with the same disorder. The extent to which the

¹ Further details on the structure and mode of origin of these cysts will be found in another work by the author, "Diagnosis and Treatment of Dyspepsia," and also in a paper by him, Med.-Chir. Trans. vol. xli.; also in Dr. H. Jones' work, p. 115.

² Cellular Pathology, Chance's Translation, p. 340.
DISEASES OF THE STOMACH.

degeneration proceeds differs in individual instances, as also do the signs of the accompanying catarrhal action. During life diarrhoea is often present, especially when leucocytæmia or albuminuria have co-existed;¹ in other instances I have observed this change associated with absolute anorexia, and in one case with great irritability of the stomach and vomiting. I have also found the disorder associated with much hyperæmia of the stomach, together with thickening and induration of the mucous membrane, and with fatty degeneration of the epithelium in parts where the specific lardaceous changes were but little apparent. These present the well-known reaction of a brownish-red colour with iodine, extending to variable depths of thickness in the mucous membrane, which is also usually simultaneously found in the villi of the intestines. In the stomach, in some instances, all traces of the epithelial cells are destroyed, and the contents of the tubes are converted into the refracting, homogeneous, irregular masses, into which the histological elements of the tissue are always changed in cases of this disease.

The exact relationship borne by this degeneration to the catarrhal conditions has not as yet been fully elucidated; it is probable that the two disorders may proceed pari passu; and such a combination is most prejudicial to the digestive process, as is seen from the rapid and marked emaciation which is so common an attendant on the lardaceous disease.

The Diagnosis of chronic catarrh of the stomach presents many difficulties, and in some cases the recognition of its aetiological relationships is necessary for its successful treatment. Among these may be especially mentioned the forms when vomiting occurs from alcoholic excesses, from albuminuria, and from congestion through cirrhosis of the liver, to which, however, no further allusion appear necessary than the descriptions already given.

The chief points of distinction from atonic dyspepsia have been already alluded to.

The distinction between chronic catarrh and disturbance of the functions of the stomach from nervous derangement may be difficult in some cases of hypochondriasis, and also occasionally when vomiting forms a prominent symptom of the former class.

With respect to hypochondriacal affections, the diagnosis is often obscure, particularly as both forms are not unfrequently simultaneously present. Pain and severe uneasiness are more constantly complained of in hypochondriasis. Pyrexia, thirst, acidity, flatulence, or other disturbances of digestion, especially when associated with impairment of nutrition, are more distinctive of catarrh. The tongue also affords, in some cases, a reliable clue to the nature of the disease. The character of vomiting in catarrh is less easily mistaken for that of nervous origin. In the former it is rare and only occasional,

and mucus is an almost constant product. In neurotic conditions the vomiting is never constant. It occurs soon after food. It is rarely associated with cachexia, or with the signs of disordered digestion just indicated. The existence of an hysterical diathesis, or of some of the other distinguishing features of the neuroses, is usually also a sufficient guide to an accurate diagnosis.

The diagnosis from ulcer and cancer may be doubtful in those cases when vomiting is frequent, and especially when hæmatemesis occurs. Hæmatemesis in chronic catarrh is, however, almost invariably associated with congestion, and the diagnosis of its origin must depend mainly on the absence of severe pain, aggravated by food, and on the discovery of causes of obstruction to the venous circulation in the liver, heart, or lungs. On the other hand, when chronic inflammatory action is complicated by neuralgic pain, we have other criteria in the absence of hemorrhage or of the signs of a tumour.

Tendereness on pressure also is entirely absent, or exists only in a much slighter degree in catarrh than in cases of ulcer and cancer.

The Treatment of chronic catarrh of the stomach requires considerable diversity, according to the varied ætiological conditions under which the disease may occur.

In cases succeeding an acute attack the sedative plan of treatment is that which is usually followed by the most favourable results. Of all single remedies bismuth is the one which ordinarily proves the most efficacious, and it may often be advantageously combined with magnesia, or, where there is much nervous irritability of the stomach, with morphia and hydrocyanic acid, in the manner before mentioned. The chief indications for its use in this state are, pain or uneasiness at the stomach after taking food, together with a sense of load at the epigastrium, followed by acidity and combined with a red and irritable tongue, or with one furred in the centre and red at the tip and edges.

The value of opium will be further treated of in relation to some of the special forms of the disorder.

In other cases, of longer standing, more direct astringents are serviceable. The most useful of this class are the nitrate or oxide of silver, the former of which should be given in the solid form in doses of a quarter of a grain to one grain, combined with opium, the latter in doses of one grain to two grains; the oxide of zinc, in doses of two grains to three grains; alum, in solution in doses of two grains to five grains; tannin or decoction of oak bark; and matico.

Arsenic in minute doses has been recommended by some writers as a valuable remedy. I have tried it in some cases, but hitherto without success: and we have not as yet obtained any definite indications for those in which it is likely to prove suitable; while it certainly aggravates the affection in cases for which it is not adapted.

The mineral acids are very useful, when given with meals, as aids to digestion, particularly when the atonic condition is also present.
It is only in marked forms of irritation that their use is contra-indicated. Their utility is sometimes considerable in the dyspepsia of phthisis, as pointed out by Trousseau, although in this form, when the irritability of the stomach is very marked, sedatives and alkalies often succeed better—or at least until the acuter degree of the affection has subsided. They are also often of peculiar advantage in cases of irritative dyspepsia associated with deposits of oxalate of lime in the urine, and they are occasionally of service when the urine is phosphatic; but their influence in relieving either of these conditions depends on their power of improving the digestion, rather than on any effect produced by them on the composition of the urine, on the reaction of which they have very little direct influence.

Antacids and absorbents, administered between the periods of food, are useful when flatulence or acidity are present. Where the former predominates, magnesia suspended in equal parts of infusion of rhubarb and aq. menth. pip., often gives relief. Where heartburn alone is present, a scruple to half a drachm of the bicarbonate of potassa or soda may be taken dissolved in half a tumbler of water; and this treatment is sometimes beneficial when there has been a feeling of load and uneasiness three or four hours after a meal, accompanied with great physical languor and intellectual depression: the same advantage may also be obtained by drinking a tumbler of Vichy water between the meals, and also on retiring to rest at night. They are further useful when urates or uric acid appear in the urine, and particularly in the acid dyspepsia of gouty cases. Caution, however, is required, in order that the habit of taking these substances does not become confirmed, as more permanent injury to the digestion may result from their prolonged use.

Pepsine is also often of value in this disorder. I have found it especially so in the dyspepsia of scrofulous children, where the tongue is red and irritable; but I have employed it also under other circumstances with great utility.

Purgatives are only to be employed with caution, and cases of chronic irritative dyspepsia are often aggravated by a persistence in their use. In children especially their frequent employment, and particularly that of mercurial “alteratives,” is very undesirable. Nor are these remedies indicated by occurrence of pale, yeasty stools, which proceed as often from imperfect gastric digestion as from disordered “liver.”

In some cases of long-standing irritative dyspepsia, arising chiefly from excess in eating, benefit often accrues from free purgation with mercurials, and in gouty patients of this class colchicum may sometimes be advantageously added. Podophyllin is also of use in these circumstances.

2 Whytt (Works, p. 664) recommended for persons troubled with mucous vomiting a tumblerful of lime water, to be drunk on an empty stomach in the morning.
3 See some valuable remarks on this subject by Dr. Jenner, Lectures on Rickets, Med. Times and Gazette, 1860.
Mercurial purgatives are also of use in cases of congestion of the stomach arising from disorder of the liver, even when this is so severe as to give rise to haematemesis or melena.\(^1\) They have also favourable effects in some cases of this class, when pain is present, associated with the vomiting of ropy mucus,\(^2\) though in these the subsequent administration of astringents is necessary to complete a cure.

Cases occasionally occur when a severe and long-continued inflammatory condition of the stomach, which has resisted all other remedies and also a careful dietetic regimen, yields promptly to a mild mercurial course sufficient to touch the gums; after which medicines that previously had been unavailing have proved beneficial.\(^3\) The same method has been followed by the author with success in cases when there was a suspicion of a syphilitic origin of the disorder of the stomach.\(^4\)

Habitual constipation may be relieved by two or three grains of the pill aloës dil. taken with food, which may sometimes be advantageously combined with the extract of nux vomica; or by two or three drachms of the decoct. aloës aquos. taken before rising in the morning. When piles exist, the action of the bowels may be procured by the use of the Pühlna or Friedrichshaller waters, or by a few drachms of the potassio-tartrate of soda, taken before breakfast. Castor oil also proves an excellent laxative in such cases; but the use of all these remedies should be avoided as far as possible, and the action of the bowels should be solicited by the daily use of enemata of cold water.

The employment of belladonna in doses of one-tenth to half of a grain, as recommended by Trousseau,\(^5\) also proves occasionally beneficial.

Many of the natural mineral waters have a very decided beneficial effect in restoring a healthy condition of the functions of the alimentary canal when suffering under chronic catarrhal affections. The most valuable in this respect in our own country are those of Harrogate, Bath, and Leamington. The waters of Carlsbad and Marienbad are also valuable in these complaints—the former being most useful when there is much portal congestion, and the latter when the disorder depends more on simple irritation of the gastro-intestinal canal, and also in young persons who suffer from constipation.\(^6\) The mineral waters of Kissingen, containing a large proportion of iron, are also of service when general atony or anaemia is combined with the irri-

---

1 These are the cases in which purgatives prove efficacions in the relief of this symptom (Sir T. Watson, loc. cit. ii. 435); but great care is necessary in the diagnosis, as they aggravate those in which the haemorrhage proceeds from ulcer or cancer. In some instances, however, the haemorrhage from congestion may be sufficiently severe to threaten life, under which circumstances the ordinary means for checking the flow must be resorted to.

3 This plan, laid down by Dr. Hunt (Heartburn and Indigestion, p. 73 et seq.), has been illustrated by some cases of Dr. H. Jones.

4 See also Trousseau, Traité de Thérap. i. 269; Andral, Clin. Méd. ii. p. 201 et seq.

tative state of the mucous membrane. Those of Vichy are of great general utility as alkaline remedies, and are also specially applicable to dyspepsias of gouty origin; and though their efficacy is less explicable, the springs of Pouges, Plombières, and Bagnerres de Bigorre have obtained a high reputation.

The condition arising from the abuse of alcoholic stimulants requires certain modifications of the plans above indicated. Occasional mercurial purgatives prove most undoubtedly beneficial; but when there is much irritability of the stomach or vomiting of mucus, opium has a special value. Its action may often be assisted by its combination with astringents, and particularly with the compound kino powder. Its beneficial effect appears to be of a twofold character: locally, it allays the irritation of the stomach, and checks the excessive mucous secretion; while, by tranquilizing the nervous system and procuring sleep, it restores the tone of the digestive organs, and frequently enables the patient to digest solid food. Opium is also of use in cases of subacute inflammatory action, combined with great nervous irritability, and where atony also exists; it may often be given with advantage combined with nitrate of silver, as before recommended.

The simple bitters may be used in these cases when the acuter symptoms have subsided. Strychnia, or nux vomica combined with the mineral acids, or the oxide of zinc, are also remedies which are specially applicable to the state of combined disturbance of the nervous system and of the digestive functions which these cases exhibit.

The disturbance of the digestive organs associated with albuminuria is often greatly relieved by free purgation with the compound jalap powder, as pointed out by Dr. Budd. The vomiting is, according to the author's experience of the disease, more effectually checked by ice than by any other remedy. In these cases an animal diet often suits better than a vegetable, and large quantities of slightly underdone meat may sometimes be taken with considerable advantage. Creosote, as recommended by Rayer, as a means of checking vomiting from this source, is sometimes also useful; but its efficacy is somewhat uncertain.

The irritative dyspepsia of phthisis offers greater difficulties to a complete cure than almost any other of the forms of this disorder. One essential point to be borne in mind with regard to it is, the necessity of chiefly employing sedative remedies; and of these I have found none so efficacious as hydrocyanic acid, the value of which remedy is, I believe, more marked in this disorder than in almost any other form of dyspepsia. It may be most usefully combined with the carbonates of potassa or soda, and given in combination with infusion of calumba twice or three times daily, in the intervals of meals.

Bismuth may also be employed with advantage, especially when

1 Trousseau, Clin. Méd. ii. 379.
3 Loc. cit. p. 248.
4 Mal. des reins, ii. 317.
there is diarrhea, under which circumstances its combination with opium or morphia is indicated.

The dyspepsia of scrofulous children—in whom the tongue is red and irritable, the complexion sallow, the spirits uneven, the general strength deficient, as shown by frequent complaints of lassitude, the appetite irregular and often voracious, but not unfrequently perverted, and the bowels irregular, the motions being sometimes loose and pul
taceous, and at others scanty and confined, but generally pale and offensive; and who often complain much of thirst—or of those of relaxed and atonic constitutions, in whom the external signs of scrofula are not well marked, is another form which requires great care both in treatment and diet. This caution applies especially to the use of purgatives, and particularly to mercurials, which seldom fail to aggra-
vote the condition.

The first and most essential point to be attended to in such cases is the regulation of the diet, both as to quality and quantity: all indigestible substances are to be carefully eschewed, and the amount of animal food is to be strictly limited until marked improvement in the diges-
tion has taken place. ¹ Great care is necessary also in ensuring the due mastication of food; and when children have acquired the habit of performing this imperfectly, they often require to be carefully watched during some weeks, until it has been overcome. Animal food may in such cases often be advantageously minced; but it must be remembered that the necessity of mastication is equally to be insisted on with all the food taken.

Mercurial purgatives are contra-indicated, and constipation is to be met by small doses of rhubarb and soda, or by castor or olive oil. A few stewed prunes may often be advantageously allowed with the meals; but other fruits, with the exception of strawberries, are, as a rule, to be avoided. The use of vegetables is only to be very cautiously permitted; and in severe cases they are to be forbidden.

As long as marked irritation persists, it is desirable to continue the use of sedatives, and of these bismuth is the most efficacious; but small doses of the carbonated alkales, with one or two drops of hydrocyanic acid combined with infusion of calumba, may be given.

The condition of atony which underlies these cases is best treated by pepsine and iron; the latter should be given in the neutral form or combined with alkales; and, when the stomach permits of its use, the administration of cod-liver oil is often markedly beneficial. General hygienic measures are also carefully to be observed, and particularly

¹ In carrying out this system the physician will often have to encounter no little diffi-
culty from the friends of his patient, who, seeing the loss of flesh and strength, not un-
frequently endeavour to remedy the weakness by increased food, wine, and tonics—a plan which unfailingly tends to aggravate the symptoms, while an opposite procedure, during a limited period, is often productive of the best results. I have known the most obstinate irritative dyspepsias of this nature cured under a system of diet from which during nine weeks animal food has been almost entirely excluded, and the patient restricted to the use of light farinaceous puddings and bread and milk.
the use of warm clothing; 1 sufficient exercise in the open air, and good ventilation of the day and sleeping apartments. Cold or sea bathing must be regulated by the vigour of the reaction of the skin. Sponging with salt and water is sometimes advisable.

The warm bath, on the other hand, is frequently beneficial when the stomach is irritable, and particularly so in children of gouty or rheumatic parents.

A very important point to be recollected in these cases is that they are liable to frequent relapses, and that under such circumstances a return for a few days to a restricted diet and a sedative treatment becomes absolutely necessary.

The weakened state of the digestion, which often remains long after signs of irritation have disappeared, requires the cautious respecting the treatment of such cases given in the chapter on Atonic Dyspepsia. The amount of food taken should be regulated by the digestive power of the stomach. 2 Stimulants should only be taken in great moderation, and of these the drier varieties of sherry, or claret, or Chablis, should be preferred.

The advantages of moderate exercise, and of change of air and scene, cannot be too strongly insisted on, and are often productive of the happiest results. One very important point to be attended to is, that patients should always wear flannel, and be sufficiently clothed to protect them against the effects of change of temperature, to which they are peculiarly liable; and the general regimen of atonic dyspepsia should be most carefully observed.

VI.—CHRONIC ULCER OF THE STOMACH AND DUODENUM.

SYNONYMS.—Perforating Ulcer (Rokitanski); Simple Ulcer (Cruveilhier); Round Ulcer; Corrosive Ulcer (Müller); Ulcer of Stomach (Brinton).

DEFINITION.—A disease characterised during life by pain in the stomach, and usually associated with vomiting, haemorrhage, and disturbances of the digestion, and terminating either in cure, or in death by hemorrhage, perforation, or marasmus. Its essential anatomical character consists in a circumscribed loss of substance of the coats

1 The exposure of young children of delicate constitutions to cold, by imperfect clothing, in the manner so commonly practised, cannot be too strongly repudiated.

2 It is very difficult to prevent patients in this condition from eating more than their stomachs can digest, under the erroneous idea of thereby regaining health and strength: it is not uncommon to find feeble subjects of irritative dyspepsia using very little exercise, and taking meat three times daily, together with a considerable quantity of stimulant, and with beef-tea once or twice in the intervals, who improve at once and rapidly on submitting to a more restricted diet. The just medium in these cases is at all times one difficult to attain, but the effects of a certain degree of abstinence are often most beneficial, and it is rarely that it is carried too far, at least in comparison with excesses in the opposite direction.
of the stomach or intestine, extending for a variable depth through their tissues, which is sometimes associated with inflammatory thickening of its margins, but is not attended by any other morbid growth.

History.—It is probable that a large number of the cases described by the earlier writers under the titles of Cardialgia, Gastrodynia, Hæmatemesis, and Mælæna were really referable to this disorder. Ulcerations of the stomach were indeed recognised by Celsus, 1 and mentioned in several places by Morgagni, 2 but their effects were confounded by other writers with rupture, either spontaneous or from violence; or they were described among the appearances produced by chronic gastritis or duodenitis (Andral, Brousais, Abercrombie). The first authors who distinctly traced the connexion of the special symptoms characterising this disease with a definite anatomical alteration were Cruveilhier and Rokitanski, who gave complete descriptions of its leading features, which have since sufficed for the basis both of diagnosis and treatment. Subsequent additions have been made to our knowledge of its pathology and etiology by Prof. Virchow and by Dr. Brinton, the latter of whom has given statistics based on a wider comparison of the published cases than had previously been attempted; and the same course has been followed by other writers mentioned below. 3

1 De Med. liv. cap. 5.
2 Epist. lxv. 3, xxix. 14, 20, lxix. 3 (Ulcerations of Stomach and Duodenum from Arscue).
Ætiology.—Frequency of occurrence. The largest data on which an estimate can be formed of the proportionate number of cases in which this disease occurs are to be drawn from the returns of Jaksch, Dittrich, and Willigk, from the hospital at Prague, who, in a total of 10,203 bodies examined, found 126 open ulcers and 224 cicatrices in the stomach and duodenum,1 representing a frequency of 3.4 per cent., a result which corresponds tolerably closely with those of Dr. King Chambers and Dr. Brinton.

The returns of Dahlerup,2 from the hospital of Copenhagen, present a marked contrast to those just quoted: in 200 bodies he found 20 open ulcers and 6 cicatrices, giving a percentage of 13 to the total number of deaths. It is doubtful whether the marked discrepancy between this observation and that of other authorities is explicable by the small number of bodies on which it is based, or by special circumstances affecting the population.

Age.—Dr. Brinton's return of 226 cases of ulcers and cicatrices, collectively, in which the age is mentioned, shows a gradually increasing frequency of occurrence with advancing years:

<table>

and allowing for the number of all persons living at these ages, the apparent preponderance of the disease in the later periods of life is very considerable.3

The disease is rarely met with in the earlier periods of life; but a doubtful case is recorded in a newly-born infant,4 another instance is mentioned by Barrière,5 in which an ulcer was formed in the duodenum in a child of six years old, Dr. Budd6 has met with it in a girl æt. 142, and Dr. Brinton7 and Dr. Buzzard8 have found it at the ages of 8 and 9.

Other returns, though based on smaller numbers, show that there is a preponderating liability to the disease between the ages of 15 and 30.

1 Dittrich's cases, I believe, include duodenal ulcers. He distinctly mentions one such, but in most of his returns the site of the ulcers is not mentioned.
2 De Ulcere Ventriculi Perforato Havine, 1841. Canstatt's and Eisenmann's Journal, 1842. The original of this work appears to have been inaccessible to most of the writers who have quoted it, as it has also been to myself.
3 There are, however, two fallacies in such an estimate: for in the first place the appearance of the cicatrix gives no information at what age the ulcer from which it may have resulted has occurred; secondly, the duration of life, in many cases even of open ulcer, is often very considerable, and therefore the discovery of either lesion at an advanced age affords no certain criterion of the date of its origin. That the ulcers may, however, frequently commence at an advanced age, is seen by a case of Cruveilhier's, Path. Anat. Liv. xx., and also by several recorded by Dr. Brinton (Ulcer of Stomach, Appendix).
4 Busch Hufeland's Journal, 1836.

</table>

Sex.—The disease appears, from the returns of numerous observers, to be between twice and three times as frequent in the female as in the male sex.

The sex of the patient appears also to exercise an influence not only on the age at which the ulcer appears, but also on that at which one of its most fatal accidents, viz. perforation, occurs, and probably in some degree on the special liability to this event. Thus by comparison of the tables of open and fatal ulcers given by Willigk and Miquel it will be seen that, in the male sex, only one-third occurred before the age of 30 (11 to 22), while of the females the proportion of cases occurring within this period to those observed at all other ages was as 34 to 41. The greater liability to perforation at early ages in the female sex is apparent from Crisp's tables, and also from a large number collected by Dr. Brinton. These show that nearly three-fourths of the instances of this event in the female sex occurred before the age of 35, while in the male sex the cases of perforation are nearly equally divided among all ages, though somewhat diminishing in frequency after that of 50 had been attained.

The absolute liability to perforation in the two sexes is a matter of some uncertainty. Dr. Brinton estimated it as about corresponding to the absolute proportionate frequency of ulcerations observed, but other authorities believe that there is a greater relative frequency among females.

1 In Willigk's cases the whole number of females examined exceeded that of the males, being 3,440 of the former to 2,766 of the latter.
2 Dr. Brinton's estimate of the relative frequency of the ulcer in the two sexes gives a smaller preponderance to the female sex than do the numbers collected by other observers.
3 In 221 cases of ulcer by Willigk there were six perforations, all in the female sex; of sixty-seven cases of perforation by Miquel, fifty-one were females; while Dr. Crisp's tables, before quoted, give a proportion of thirty-nine females to twelve males.
DISEASES OF THE STOMACH.

893

Of the influence of race and climate but little is known. But few positive facts are known regarding any influence exerted by occupation, though Dr. Copland asserts that, when occurring in the female sex, it is most common in those engaged in needlework or in domestic service. There is a general impression that the disease is most common among the poorer classes, but no certain data exists for this opinion.

Among other occasional causes which have been mentioned, but of which none can be said to have more than an occasional influence on the production of the disease, are moral emotions, bad or insufficient food, excessive indulgence in spirituous drinks, and exposure to extreme cold.

There are certain diseases to which a direct causative influence has been ascribed in the production of the complaint, and which deserve a passing notice.

Amenorrhœa is perhaps the one which holds the most important rank among these, but precise information is wanting regarding the exact relation of the two disorders. It appears to be pretty certainly established that, though menstruation is sometimes regularly maintained after ulceration, especially in middle-aged females (Brinton), yet that disturbances in this function accompany ulcers of the stomach with a greater proportionate frequency than is met with in almost any other class of disorders, except perhaps tuberculosis. We possess, however, no certain information as to the number of instances in which suppression or arrest of the menstrual flow has preceded the disease of the stomach. Cases are indeed recorded in which suppression of the menses, through cold, in previously healthy females has been immediately followed by symptoms of ulceration, and in some, even after the re-establishment of the menstrual function, the symptoms of the stomach recurred with each return of the uterine discharge. The age at which the disease is found with such frequency in the female sex appears to point in a very distinct manner to the influence of puberty on its occurrence, and Miquel states that he has observed a similar though less marked liability at the climacteric period, between the ages of 40 and 50. These facts, together with the evidence afforded by Crisp of the association of amenorrhœa with the liability to perforation, would tend to show that the connexion between the two conditions is something more than accidental, and that, as will be further considered when the pathology of the disorder is discussed, these disturbances, when preceding the appearance

2 See a case by Cruveilhier, Path. Anat. Liv. xx. Osborne also says that he has known the symptoms of ulceration to date from this cause; Dub. Med. Journ. xxxvii. p. 357.
4 See Miquel, loc. cit. 145.
5 Loc. cit.
6 Dr. Crisp found that, in thirty-nine cases of perforation, the state of the menstruation was not mentioned in twenty-five. In the remaining fourteen, it was present and regular in one; irregular, or suppressed, or had never appeared, in thirteen.
of the ulcer, may be reasonably supposed to have a direct influence on its origin.

The influence exerted by the states of anæmia or chlorosis on the occurrence of ulceration is less evident. They have been very frequently observed in cases of perforation which, under these circumstances, may in part be due to the absence of sufficient vitality to allow of the protective thickening of the edges and base of the ulcer, by which this accident is commonly prevented. It is stated, however, by Miquel, that a sound condition of health has often in the female sex immediately preceded the ulceration.

Tuberculosis is met with in a great number of cases, but, as shown by Dr. Brinton, "the percentage of tubercle in cases of gastric ulcer does not seem to exceed its average in all persons indifferently;" nor do other diseases of the lung appear to exert any direct influence on its production.

The coincidence of the ulcer with the puerperal state mentioned by Chaussier has been brought into prominence by Jaksch's returns, who found that, of 91 females, it occurred in 10 during the period of child-bed. Rokitansky was of opinion that the occurrence of intermittents predisposed to the disorder, and Engel says that in 10 per cent. of his cases the patients were syphilitic. Krauss says that the disease has commenced after suppression of haemorrhoidal discharges; Miguel, after the healing of old ulcers on other parts of the body. The association of the disorder with diseases of the liver will be alluded to in the history of its pathology.

Of the other diseases with which it is most commonly found associated may be mentioned those of the heart, though by no means exhibiting a great frequency of occurrence in proportion to the whole number of cases dying of these disorders.

Another affection which appears to act as a direct cause of these ulcers, but the effects of which are remarkable as being almost wholly confined to the duodenum, are burns of the skin. Their influence in this respect was pointed out by Cumin, Dupuytren, Cooper, and Long, and was more fully brought forward by a collection of cases published by Mr. Curling, and in a memoir by Mr. Erichsen. Mr. Holmes has recently given further illustrations of their comparative frequency; in 125 cases of severe burns collected by him, the duodenum was ulcerated in 16, and other portions of the intestines in

---

1 Especially by Crisp.
2 Prager Viertel-Jahresch. vol. xl. p. 7. As, however, he does not give the whole numbers on which this calculation was founded, its relative value can scarcely be estimated. The evidence of disturbance of the stomach from a syphilitic taint does not show conclusively that the cause is due to ulceration. See Andral, Clin. Méd. ii. 201 et seq., and Höring, Schmidt's Jahrbucher, 88.
3 Two cases, loc. cit. 148. See also a case quoted by Cruveilhier, Liv. xx., where the disease in the stomach commenced in a patient aged 62, after the healing of an ulcer in the skin.
4 Lec. Or. p. 521.
8 Syst. of Surgery, vol. i. p. 733 et seq.
The earliest period at which the ulceration has been discovered has been on the 4th, 5th, or 6th days. The age of the patient exercises no influence on the result, nor does apparently the situation of the external injury.

**Morbid Anatomy.**—It has been already stated in the definition above given, that the essential anatomical alteration of this disease is an ulcer or ulcers of its coats.

The term as thus used is not, however, applied to all forms of ulceration of the mucous membrane, and it does not embrace either the superficial or the follicular erosions, which have been previously described as found in catarrhal inflammations of the stomach. Nor, in the author's opinion, should the superficial haemorrhagic erosions be included in the definition of this disease, though its relation to the latter form will be again alluded to.

As distinguished from the above forms, the chronic or perforating ulcer of the stomach is one which extends for a greater depth in the tissues, sometimes passing only through the mucous membrane, at others penetrating the muscular tissue, and even the peritoneum.

(a) **Character and Appearance of Ulcer.**—It is found in two conditions, which, as they are supposed to represent either different stages or variations in its mode of progress, it seems not unimportant to distinguish from one another.

The first of these, which is believed to be that in which the ulcer is found soon after its origin, presents a sharply defined loss of substance of variable depth in the coats of the stomach: it may then, when affecting only the mucous membrane, have a flattened appearance, with clean cut edges, looking as if they had been punched out of the tissue; when, however, the destruction has extended more deeply, it generally presents, even at this period, an appearance somewhat resembling that of a funnel whose apex is directed towards the peritoneum. The edges and floor in this stage are smooth and even, the former seldom presenting any swelling or elevation above the surrounding tissue; the base, however, often shows a softened puffy look, and minute sloughs may sometimes be found upon it. In some cases, however, the ulcer has been found with a mass of blackened blood adhering to its base, or with an infiltrated extravasation of blood into its margins, or surrounded by a zone of injection in which petechial extravasations have occurred,—appearances which, as will be seen, are of considerable interest in relation to the pathology of this

---

1 The clinical history of this disorder is in many points so fully elucidated by the pathological conditions observed in the stomach, that a departure from the usual order followed in this work appears in this instance desirable.

2 This funnel-shaped opening, as has been observed by Virchow, does not always extend vertically into the tissue in its whole circumference, but one side may be vertical and the other sloping.

A SYSTEM OF MEDICINE.

disease, and to the experiments conducted with a view to its artificial production in animals.

In this stage the ulcer frequently perforates; but the morbid anatomy of this result of the disorder will be separately described.

When the ulcer has existed for a longer period, its walls and floor undergo an inflammatory thickening, through which its funnel-like shape becomes more distinct, and it acquires a stratified and crater-like appearance, which is less distinct in its earlier stages. This appearance is due to the different coats being involved in areas which progressively diminish from within outwards, the mucous and sub-mucous tissues being destroyed over a wider surface than the muscular, which thus forms the first step, and through the opening in which the thickened peritoneal and sub-peritoneal tissues are seen penetrated in a smaller extent by the progress of this disease.

The whole tissue of the wall is thickened around the ulcer, and the different coats become blended together, sometimes for a considerable distance around its margin. The new tissue by which this is effected consists of an amorphous or finely granular intercellular substance, in which are imbedded nuclei more or less thickly scattered. At a later period it is developed into an imperfectly fibrillated tissue. Occasionally, but not commonly, granulations may be seen on the sides and base of the ulcer.

The tubular glands in the immediate neighbourhood are sometimes destroyed by this growth, or villous or polypoid vegetations may be developed on the mucous surface surrounding the ulcer; but in the majority of cases these appearances are not observed, and the ulcer exists only as a conical-shaped perforation of the coats of the stomach, surrounded by a thickened and indurated cicatricial margin, and resting on a base having the same characters. In rarer instances the ulcer has been found associated with suppuration in the coats of the stomach, leading to secondary thrombosis and suppuration in the portal vein.1

In some cases the retraction of the deeper layers may give the mucous membrane an excavated appearance, and this may proceed to the extent of causing the edges of the mucous membrane to meet in the centre (Krauss); but, ordinarily, when cicatization ensues, it proceeds by granulations from the base, and the previous site of the ulcer is marked by a cicatrix of variable size, uncovered by mucous membrane, and surrounded by stellate radiating lines extending into the surrounding tissue.

(b) The size of these ulcers varies from that of a fourpenny-piece to a diameter of five or six inches.2 The larger diameters mentioned have been almost entirely met with in cases where there was reason to believe that the disease had been of long standing; and those of more recent formation, or which have run an acute course, have

1 Dr. Bristowe, Path. Soc. Trans. ix. 275.
2 A case is given by Law, Dub. Hosp. Gaz. ii. 51, of an ulcer measuring 6 in. by 3 in. quoted by Lees, (Diseases of Stomach).
seldom exceeded that of a shilling or half-a-crown. Perforating ulcers have been artificially produced\(^1\) not larger than a pin’s head in diameter.

\((c)\) The shape of the ulcer is usually round or ovoid. Coalescence of one or more may give, however, various irregularities of outline; and instances are recorded in which they have been found surrounding the whole circumference of the pylorus.

\((d)\) The number met with in any single subject varies.

Dr. Brinton says that, out of 536 cases, two or more were present in 113, or in 21 per cent.\(^2\) Instances, however, are mentioned in which three, four, five, or even more open ulcers have been found in the same stomach; and Krauss says that, in the cases of duodenal ulcers observed, a plurality has been found in one-third. The simultaneous occurrence of ulcers in the duodenum and in the stomach is also, comparatively speaking, a frequent event.

\((e)\) The seat of the ulcer is much more commonly in the stomach than in any other portion of the intestinal canal. It is very seldom met with in the oesophagus,\(^3\) and much less frequent in the duodenum\(^4\) than in the stomach, but instances are recorded in which similar ulcers have been discovered in lower portions of the intestines.\(^5\)

The seat of the ulcers in the stomach exercises an important influence on the progress of the disorder, and therefore deserves especial mention. The largest statistics on this subject are given by Dr. Brinton, who, in 220 cases in which the site was recorded, found that eighty-six were on the posterior surface; fifty-six on the smaller curvature; thirty-two on the pylorus; thirteen on the anterior and posterior surfaces, which frequently existed together, and were often opposite to one another; ten on the anterior surface only; five on the greater curvature; and four in the cardiac pouch. Rokitansky’s remark, that the ulcers are more commonly seated in the immediate neighbourhood of the curvatures rather than directly upon them, has been fully confirmed by more extended observation.

The majority of ulcers in the duodenum are situated in the upper horizontal portion.\(^6\)

\((f)\) The progress of the ulcer, when once formed, tends either to

\(^1\) Müller, loc. cit. 273.

\(^2\) He does not, however, state whether these include cases where recent ulcers and cicatrices of older ones were present together,—a very common condition.

\(^3\) A case of this kind is given by Mr. Flower, Med.-Chir. Trans. xxxvi.

\(^4\) Willigk found for 225 cases in which the stomach was affected only 6 cases of ulcer in the duodenum, and Trier, on the other hand, gives, as the relative proportional frequency in these parts, 28 cases of duodenal ulcer, as contrasted with 261 when it was found in the stomach. It is not, however, unlikely that cicatrices in the duodenum may be frequently overlooked: so that no absolute reliance can be placed on these numbers.

\(^5\) Albers, Die Darmgeschwüre, p. 474 et seq. Lebert and Clauss, Ueber Spontan Darm-Perforationen, Diss. Inaug., Zurich, 1856,—a case where a perforating ulcer existed in the colon simultaneously with another in the stomach (quoted by Krauss); Lebert, Handb. der Prakt. Med. ii. 369. Dr. Dickinson, Trans. Path. Soc. 1867, for "Colon." Cases where large ulcerations in the intestines resulted from embolism are given by Panum, Virch. Archiv., xxv. See also on this subject Mr. Holmes’s article, before quoted.

\(^6\) Of 47 cases collected by Krauss, only two were situated in the lower horizontal part.
cicatization or to extension through the coats of the organ, thus leading either to perforation of the stomach or to the invasion of neighbouring organs through adhesions previously contracted.

(q) That cicatization is by far the most common result is shown by the returns before quoted, where it is seen that cicatrices are found nearly twice as frequently as open ulcers.\(^1\)

The process by which the cicatization is accomplished has been already described, but its final results differ considerably, according to the depth and superficial extent of the ulcer, the adhesions which it has contracted to neighbouring organs, and the amount of thickening which has taken place around its base and margin.

In many cases the process is not complete, and there is a proclivity to the return of the ulcerative action in the cicatricial tissue.

When the loss of substance has not penetrated deeply, or when cure has followed rapidly on the destruction,\(^2\) the site of the injury is only marked by a white spot in the mucous membrane, and attended with little or no puckering or contraction; but in others a similar appearance, with radiating stellate lines proceeding from it, may be seen externally on the peritoneal covering.

In cases, however, where the ulcer has extended deeply, and where there has been great thickening of its base and margin, the contraction of the fibrous tissue, by which the loss of substance is replaced, may lead to alterations in the form and shape of the stomach. Amongst the most remarkable of these are cases in which, from ulcers seated in the smaller curvature, the pyloric and cardiac orifices have been drawn into close proximity to one another;\(^3\) or where the constriction extending around the centre of the stomach has given it an hour-glass shape, involving a special tendency to dilatation of the fundus;\(^4\) or where the whole organ may have been found reduced to the size of the intestine.\(^5\) Strictures also of the orifices are by no means uncommon, though much more frequent in the pyloric than in the cardiac extremity.\(^6\) Extreme degrees of stenosis are rare (only about once in 200 cases—Brinton). When affecting the pyloric orifice, they are usually attended with extreme distention of the whole viscus, and are associated sometimes with thinning, and at others with thickening, of its muscular coats, while in a third class this dilatation is limited to peculiar pouch-like formations in the pyloric portion.\(^7\)

---

1 Dr. Brinton, from a smaller number of cases, deduced that open ulcers and cicatrices are met with in about equal frequency. The result of the larger returns points to an interesting fact as regards the curability of the disease, which will be the subject of further remark.

2 Mr. Curling has given a case where cicatization of an ulcer in the duodenum after a burn was found commencing on the tenth day; another when it was completed at the eighth week; and Mr. Holmes has recorded one where cicatization in the duodenum was completed within twenty-eight days after the burn in which it had probably originated.

3 As in a case by Bärnhoff, quoted by Henoch, loc. cit. \(\text{142}\), where the pyloric and cardiac orifices were only 1\(\text{2}\) inches distant.

4 In cases by Cruveilhier, Budd, and Brinton.

5 Jaksch, loc. cit.

6 For a case of constriction of the cardiac orifice, with great consequent diminution of the size of the stomach, see Drasche, Wien. Med. Wochenschr. \(\text{1854, No. 67 (Müller).}\)

7 See two cases by Cruveilhier, Anat. Path. fol. liv. \(\text{xx}.\) Also a case quoted by Brinton, Dub. Med. Journ. ii. \(\text{494.}\)
Similar constrictions have also been observed in cases where cicatrization has ensued in ulcers situated in the duodenum, the effects of which on the stomach are very similar to those produced by narrowing of the pyloric orifice. Sometimes, however, dilatations, for which an explanation is not easily afforded, have been seen immediately beyond and below the constricted part (Krauss). These contractions may also lead to peculiar bending and twisting of the intestine, and in one case, recorded by Frerichs, \(^1\) to further consequences due to the thickening of the tissue external to the bowel, resulting in complete obliteration of the vena portae.

The contractions of the cicatrix tissue, and the changes thence resulting, are, however, not always necessarily attended with closure of the ulcer, which in some of the cases just quoted has still been found open.\(^2\)

\(h\) The extension of the ulcer proceeds either by the destruction of the cicatrix tissue in its base and margins, or it may occur before this product has been formed. In the former case it is characterised by softening and liquefaction of the superficial layers of the base, while at the edges where it is taking place the thickened mass disappears, and the border presents the same sharply-cut limitation which characterised the first stage of the disease. In some instances this may be found affecting only part of the circumference, and thus affording a criterion of a return of the destructive process in an ulcer of old standing.

During its progress the larger vessels of the stomach are not unfrequently opened, and prove one of the sources of the haemorrhage so frequently observed.

The rapid extension of an ulcer in the early stages of its formation is one of the most frequent causes of the accidents next to be considered.

\(i\) Perforations of all the coats of the stomach may be divided into two classes—namely, those in which an opening has ensued from its interior into the abdominal cavity, and those in which this event is prevented by adhesion to the surrounding viscera. The frequency with which the first-named of these events occurs has been calculated by Dr. Brinton, from 257 recorded cases of open ulcer, as being about equal to 13\(\frac{1}{2}\) per cent. of all cases of ulceration; but, as this average is based upon an estimate of the comparative frequency of cicatrization, which there is reason to believe is considerably below that really found, so it is not improbable that the actual proportion of the cases in which this accident occurs is less than Dr. Brinton was disposed to believe;\(^3\) though, as Cruveilhier has pointed out, it is

\(^1\) Dis. of Liver, Syd. Soc. Trans. i. 272.
\(^2\) See also a case of contraction of the duodenum by a recent ulcer, Duckek, Prag. Viertel. Jahresh. xxxvii. 51, 1853.
\(^3\) Of Willigk's 231 cases of ulcers and cicatrices, as before quoted, only six had perforated, and Dittrich in 106 cases only met with ten cases of perforation. It is probable, also, as Miquel has observed, that in collections of isolated cases a greater number of instances of perforation will be found, owing to the remarkable character of the event conducing
much more frequent in cases of simple ulceration than in those of
cancer of the stomach.

The influence exerted by age and sex on this event having been
already alluded to, does not appear to require further discussion. A
very important feature in determining the character and nature of
this result is to be found in the position of the ulcer itself in the
wall of the stomach and duodenum. When this is situated in parts
where the amount of movement and distension is the least, and where
adhesions are most easily formed to surrounding parts, the probability
of the accident is considerably less in comparison with the cases
where opposite conditions prevail;¹ and thus ulcers situated in the
anterior wall of the stomach and on the lesser curvature are more
liable to perforation than those in the posterior wall and the greater
curvature; while, of the duodenal ulcers,² those situated in proximity
to the head of the pancreas possess almost an immunity from this
event.

Precise figures regarding the condition of the ulcer at the time
of perforation are wanting; but, though the event is very frequent
in those of old standing, there yet seems reason to believe that it is
comparatively more frequent in the early stages of the disease, before
the protective thickening which subsequently ensues has had time
to form. It seems not impossible that the depth to which the
tissues are primarily affected by the process which gives rise to
the slough in which the ulcer often appears to originate has no
small influence in accelerating or retarding this event.

When it occurs in those of recent origin, or when there are no
adhesions to neighbouring organs, the peritoneal covering gives way
after the previous formation of an ash-grey slough, the final yielding
of which is generally determined by distension of the stomach, or
by the effort of vomiting. The external opening is usually con-
siderably smaller than the inner surface of the ulcer; its edges
are generally sharp and well defined, like those of the rest of the
ulcer, but sometimes they may be slightly ragged from the final
rupture of the necrotized tissue. They are never, however, so ragged
and thinned, nor do they present the same pulpy and transparent
to its publication, while those of simple ulcer are not so commonly thought worthy of
being recorded.

¹ Of 191 cases of perforation of the stomach by ulcers collected by Dr. Brinton, 69
were on the lesser curvature, 55 on the anterior surface, 11 on the posterior surface, 9 at
the pyloric extremity, 10 at the cardiac end, 4 in the middle of the organ, and "in no
less than 24 there were two ulcers opposite one another on the anterior and posterior
surfaces of the organ—the former being the site of the perforation, while the latter was
in most instances firmly adherent to the pancreas." It is interesting to compare these
returns with those of Jakob relative to the comparative frequency of the sites of adhesion.
These occurred in 22 out of 57 cases of ulcer and in fifteen they were between the pos-
terior surface or lesser curvature of the stomach and the pancreas; in five between the
pyloric portion or lesser curvature and the liver; while in one only there was adhesion
to the mesentery, and in one to the spleen.

² Krauss states that, of 16 cases of perforation of the duodenum from this cause, in
12 the event had occurred in ulcers situated in the right wall of the upper horizontal
posterior,
DISEASES OF THE STOMACH.

appearance as is seen in the case of perforation by post-mortem solution, from which the perforation is further distinguished by the characters of the alteration of the mucous membrane in the latter.¹

When adhesions have formed to neighbouring organs, or when protective thickening has occurred in the sub-peritoneal tissues, the future progress of the ulcer is subject to many varieties. Thus, it may deeply invade the tissue of the liver, spleen, or pancreas, giving rise to extensive haemorrhage from their vessels;² or deep fistulous openings may form into the interior of these organs, in which also, in some cases, large primary abscesses may be found communicating with the ulcer; while, in the case of the liver, secondary abscesses are by no means uncommon.³ In other but rarer instances perforations may occur in the diaphragm,⁴ and the ulcer may give rise to pleurisy or to gangrenous inflammation of the lung, or may communicate with the bronchi; or perforations may ensue into the transverse colon,⁵ or externally through the anterior wall of the abdomen.⁶ Other events which have been recorded are erosions of the pancreatic⁷ and biliary ducts; and sometimes in the case of duodenal ulcers, the latter have been found either in a state of suppuration,⁸ or obstructed, thus giving rise to jaundice,⁹ or even to bursting of the gall-bladder;¹⁰ while in other instances perforation of this latter structure by the ulcer has been noticed;¹¹ in others the stomach has been so bent upon its axis, as to

¹ Cases are, however, recorded where the perforation took place, not at the seat of the ulcer, which had caused stricture of the pylorus, but from rupture of the fundus of the secondarily dilated stomach (Siebert, quoted by Müller, p. 110). A somewhat similar incident in a case of cancer of the stomach is recorded by Andral, Clin. Méd. ii. p. 75.

² Opening of the portal vein by a duodenal ulcer has been recorded by Rayer, Archives Gén. viii. 66; Andral, Prac. Path. Anat. ii. 177.

³ See some cases by Dr. Murchison, Path. Soc. Trans. xvii. 145.

⁴ These, however, are generally caused by fistulous communications through adhesions with other organs, or with circumscribed abscesses. See cases by Dr. Habershon, Path. Soc. Trans. 1847-8, p. 253; Obs. Alimen. Canal, 1862, p. 82: Cruveilhier, Arch. Gén. de Méd. 1856, p. 155: also by Rokitanski and Jaksh.

⁵ See a collection of the published cases of this nature in an able memoir by Dr. Murchison, in Gastro-Colic Fistula, Ed. Med. Surg. Journal, 1857-8. This perforation is much more frequent in cancer than in ulcer of the stomach; of 33 cases 9 or 10 only were from simple ulcer, 21 from cancer.

⁶ Dr. Murchison has collected all the cases of Gastro-Cutaneous Fistula hitherto recorded in a memoir, Med.-Chir. Trans. xii. There is a striking contrast between these and Gastro-Colic Fistula in regard to the comparative frequency with which they are connected with simple and cancerous ulceration; for whereas the number of instances in which openings into the colon are associated with cancer greatly exceeds that in which they are caused by ulcers, Gastro-Cutaneous Fistula would appear to be nearly twice as frequently the result of simple ulcer as of cancer. This difference is probably due in part to the comparative rarity of simple ulcer "in that part of the stomach nearest the colon, whereas of simple ulcers ending in perforation a very large proportion is found in the anterior surface." Perforations externally caused by ulcer may be distinguished usually by the smoothness of the opening, while those from cancer are ragged and villous through the extension of the growth in the skin.

LEEDS SCHOOL OF MEDICINE
form a second direct communication with the duodenum through the adhesion and perforation of their walls, thus brought into apposition, the pyloric ring remaining, in some cases, open and bridging the newly-formed aperture.\(^1\)

\(\text{(b)}\) *Escape of the contents of the stomach into the cavity of the abdomen* is almost invariably followed by more or less general peritonitis,\(^2\) associated with tympanitic distension, which sometimes proceeds to an extreme degree, owing to the escape of air through the opening in the stomach or duodenum (Abercrombie).

In other cases, however, where, as Dr. Brinton observes, a gradual filtering of the gastric contents has taken place through a small opening in its wall, or through incomplete adhesions, and particularly through those which are formed between the stomach and omentum, circumscribed abscesses, sometimes of considerable size, and communicating with the ulcer, may be formed. Their boundaries are then variously constituted by adhesions between the ulcer and the anterior wall of the abdomen, or with the diaphragm, liver, colon, pancreas, or spleen, which latter organs may be sometimes partially or completely destroyed; or the abscesses may be limited to the cavity of the small omentum, a variety of which Dr. Brinton has collected twenty instances. Such abscesses may be more or less permanent, but the adhesions may again give way; and this event is then followed by more general peritoneal inflammation.

In some cases, where ulcers of the duodenum have opened into the loose cellular tissue bounding its posterior wall, the abscesses resulting have passed upwards through the mediastinum towards the neck,\(^3\) or have opened outwards between the sixth and seventh rib on the right side, or posteriorly at the shoulder-blade.\(^4\)

\(\text{(l)}\) *Haemorrhage* from the ulcer requires a short separate consideration.

Cruveilhier\(^5\) divided them into slight, moderate, and excessive, and pointed out that those of the two first classes came from the smaller arteries and veins of the mucous and sub-mucous tissue, which, when examined under water, can be seen either eroded and obstructed by recent and easily-detached clots, or closed by more firmly-attached coagula. Copious haemorrhages may, however, sometimes be determined by venous congestion, since in some cases of this nature no

Chomel (Andral, Prec. Path. Anat. ii. 116), where there was a fistulous communication between the duodenum, gall-bladder, and colon.

1 Rokitanski, loc. cit. ; Cruveilhier, Rev. Méd. iii. 36. Dittrich, Prag. Viertel Jahresch. xiii. In the latter case the communication took place through the pancreas.

2 A remarkably exceptional case is recorded by Bardeleben, in which, though the patient lived twenty-four hours, and purgative medicines, together with other contents of the stomach, were found in the peritoneal cavity, there were no signs of general inflammation of its lining membrane. Virch. Archiv. v. 250.

4 Gross. El. Path. Anat. 532. Also a case by Dr. Stretton of Worcester, Lond. Med.-Phys. Journ. vol. 1x. p. 43. In the latter instance there were openings in both the last-named situations, and food passed through the fistulous opening between the ribs five minutes after it had been taken.

5 Archives Gén. 1856.
other source has been found for the blood effused than varicose dilated veins in the mucous membrane of the stomach.\textsuperscript{1} The tendency is increased by hyperæmia, however originating, and especially by that occurring during the digestive act. It is probably also in this latter cause that an explanation must be sought for the cases where haemorrhage has been increased or caused by moral emotions\textsuperscript{2} or by the menstrual period.\textsuperscript{3}

Larger haemorrhages most commonly arise from the perforation of vessels of considerable size in the deeper coats. This event is indeed usually prevented by the coagulation of the blood in their interior, and by the resistant character of their walls; and it is by no means uncommon to find an obstructed vessel in the floor of an ulcer, in cases where no considerable haemorrhage has taken place during life. The ulceration of the obstructed vessel, nevertheless, may proceed beyond the point to which the protective thrombosis has extended. In some cases extensive haemorrhage has taken place in the early stages of ulceration, but in others the whole ulcer has been found cicatrized except at a point where an eroded artery, giving rise to fatal haemorrhage, projected into its floor.\textsuperscript{4}

Another source of both the larger and also of the smaller hemorrhages is to be found in the penetration of the vessels of adjacent organs with which the ulcer has formed adhesions, and among these the splenic artery, which in its tortuous course often comes in contact with the stomach, affords a large proportion of instances of haemorrhage. Perforations are, however, recorded of the portal veins and of the hepatic artery from duodenal ulcer.

When, on the other hand, haemorrhage ensues from the main arteries of the stomach, it usually proceeds from those situated in the larger and smaller curvatures, and especially from the superior pyloric or coronary artery.\textsuperscript{5} Moreover, as Miquel has also remarked, the presence of a large vessel at the base of an ulcer affords, by its resistance to the ulcerative process, a certain protection against the occurrence of perforation.

\textit{(m) The condition of the mucous membrane} of the stomach offers also certain varieties. In many cases it is found perfectly healthy; in others polypoid vegetations, or extravasations and haemorrhagic erosions, may be found around the margins of the ulcer; signs also of chronic or recent catarrhal inflammatory action are not unfrequent. These

\textsuperscript{1} Cruveilhier, Anat. Path. Liv. x. Also Frerichs.
\textsuperscript{2} Ib. Liv. xx.
\textsuperscript{3} Ib. Liv. xx.
\textsuperscript{5} Hence there is a certain contrast between the liability to perforation and haemorrhage determined by the anatomical position of the disease in the walls of the stomach, since ulcers situated on the anterior surface, from which, as has been seen, perforation is most likely to ensue, rarely invade in their progress any of the larger vessels, whose branches are only sparingly distributed to this portion of the organ. Thus, of 52 cases of fatal haemorrhage collected by Dr. Brinton, the ulcer giving rise to it was in 24 instances situated in the smaller curvature, in 17 on the posterior surface, in 6 on the pyloric extremity, and in 2 only on the anterior surface.
latter are, however, most common when constrictions have occurred in the pyloric or duodenal portions of the canal. The appearances characteristic of these changes, and also the varicose dilatation of the vessels occasionally observed, do not, however, require further description in this place.

Pathology and Pathenogenesis.—While some observers attributed these ulcers to inflammation, and others, as Cruveilhier, have expressed themselves unable to explain their origin, Rokitanski separated them from the class of ordinary inflammatory ulcerations, and declared that their point of departure was from a necrosis of the mucous membrane and subjacent tissues. Virchow\(^1\) advanced the next step in this direction, by stating that the primary condition for their formation was an arrest of the circulation through a sufficient depth and area to permit the solvent action of the acid gastric juice to be exerted on the tissues deprived of the protective action of the alkaline blood. This view has received a direct confirmation from Dr. Pavy's\(^2\) experiments on the effects of the arrest of the circulation in the stomach, which have shown that this event is invariably followed by the solution of the coats of the organ, proceeding in some instances to complete perforation.

If this opinion be admitted as affording a probable explanation of many, if not most, of these cases, it follows that any causes capable of producing such an event may be competent to give rise to the ulcer in question; and among the most frequent of these appear to be extravasations of blood into the tissues of the stomach, to which a preponderant influence in this direction was first attributed by Rokitanski.

It appears, however, to be necessary that such extravasations should extend deeply, and occupy some considerable area, and that the minor petechial ecchymoses resulting from capillary hæmorrhage on the surface, and to which the name of hæmorrhagic erosions has been given, are, as a general rule, incapable of producing this effect, since the protective influence of the circulation is not, in these cases, sufficiently withdrawn, to permit of the action of the gastric juice extending deeply into the subjacent tissues.

Virchow states as his opinion, that the most frequent causes of this arrest of the circulation are obstructions of the arteries through embolism, extravasations through obstructions of the portal vein, fatty degeneration of the coats of the arteries, or even the diminished calibre of the vessels, sometimes met with in chlorosis, or extravasations caused by violent movements of the stomach in the act of vomiting.

The possibility of the direct production of these ulcers through embolism has been demonstrated by Panum’s experiments. The

\(^2\) Phil. Trans. 1863. A Treatise on the Function of Digestion, 1867.
immediate effect of the obstruction of the arteries thus produced was
seen in extravasations into the sub-mucous and mucous tissues, which
were followed by ulcerations in these parts, having all the characters
above described; 1 and Müller 2 has equally shown that very similar
results may be produced by ligature of the vena portae. 3

It has also been remarked by Virchow that both the shape and also
the most common positions of these ulcers point in many cases to their
arterial origin, and that the conical form, with the base at the
mucous surface, corresponds to the ramifications of the capillary
branches spreading outwards from a main trunk, which has been
obstructed in the deeper tissues, and thus resembling precisely the
results of arterial embolism in other parts where similar appearances
are seen.

The appearances of extravasations found in connexion with some
recent ulcers, which have been before alluded to, seem also in a great
degree to confirm this theory of their hemorrhagic origin. It may
further be noted that many of the causes to which their production
has been attributed are such as would coincide with this opinion,
though their inconstancy in this respect is easily explicable, when
we consider that though the tendency of the majority is to produce
congestion of the stomach and intestines, yet that this may proceed
to a marked degree without necessarily involving the occurrence of
such extravasations as are capable of giving rise to extensive or
depth-spreading necrosis of the coats of these organs. Some clue
may thus be gained to their frequent appearance in connexion with
disturbances of the menstruation, which are known to give rise to
great disorder in the functions of the stomach. This is further
evidenced by the hemorrhage from this organ, which occasionally
replaces that from the uterus, and which must necessarily have been
preceded by an extreme hyperemia, not only of its lining membrane,
but also of all the vessels supplying it; while the not unfrequent
coincidence of the disease with the puerperal state may be attributed
either to conditions of congestion, or, probably, in many to embolism
associated with pyemia.

A similar origin may also with great probability be ascribed to
duodenal ulcers commencing after burns of the skin; though their
site in these cases appears to require further explanation, since the
possible implication of Brunner's glands, suggested by Messrs.
Bowman and Curling, does not appear completely to elucidate
their peculiar frequency in this position under these circumstances
as compared with their comparative rarity under other conditions.

1 Virchow's Archiv, xxv. pp. 491 et seq.
2 Loc. cit. p. 272 et seq.
3 It is remarkable that cirrhosis of the liver does not more frequently give rise to ulcer
of the stomach. Frerichs only gives three cases of the latter disease associated with
disease of liver. Only one of these was associated with chronic atrophy. Forster gives
a case of ulcer of the duodenum associated with cirrhosis, Würzburg. Med. Zeitsch. 1801,
il. p. 165 (Krauss). A case is recorded by Gunsburg, Arch. Phys. Heilk., where the deter-
mining cause of the ulcer appeared to be the obstruction of a vein in the stomach itself.
The evidences of recent extravasations in several recorded cases of this nature may very properly be placed in juxtaposition with Rokitanski's observations on the frequency of hæmorrhage from the lower portions of the intestinal canal from similar causes, as pointing to their origin in intense congestion leading to rupture of the vessels. A similar explanation may thus be afforded of an instance recorded by Cruveilhier, when the symptoms of ulceration followed an attack of cholera; for although in this disease hæmorrhage is more common in the intestines than in the stomach, yet extravasations in the latter are also occasionally observed.

Dr. Copland's independent testimony confirms Virchow's opinion of the possibility of extravasation having a similar result, arising through atheromatous degeneration of the coats of the vessels of the stomach. Frerichs, also, in a case where an ulcer of the stomach followed the obstruction of the gall ducts, has pointed out that Kölliker and Müller observed the disease in the duodenum in cases where the common bile duct had been ligatured, and where also calcareous matter was deposited in the branches of the cælic axis and in those of the mesenteric arteries.

Our knowledge of other possible causes of the disease must be considered as yet imperfect. It may be questioned whether inflammatory states often, if ever, exist in the stomach to a degree sufficient to act in a manner similar to the conditions which have now been described; nor does it appear very probable that the follicular ulcerations proceeding from the solitary glands of the mucous membrane often extend beyond the area occupied by these structures, though the distribution of the anatomical elements of a lymphatic character has been shown, by Dr. Jones and the author's observations, to extend more widely in the mucous and sub-mucous tissue, than has been sometimes supposed.

Another more likely cause, though of rarer occurrence, are those cases where profuse suppuration takes place in the sub-mucous tissue, the effects of which are extremely likely to arrest the vascular supply of the mucous membrane.

However originating, the peculiar tendencies to extension and perforation seem to be especially communicated to these ulcers by the

1 Mr. Erichsen had previously pointed out only the probability of the extreme congestion of the gastro-intestinal canal acting as the cause of these lesions.
4 Dis. Liver, Syd. Soc. Trans., by Murchison, i. 137.
5 Würzburg, Verhand. vi. 474.
6 An experiment of Frerichs, Dis. Liver, i. 187, would lead to the question whether disturbances of the circulation or of the nutrition of the stomach through derangement of the nervous supply may not occasionally produce this effect. He found an ulcer of the stomach in a cat after division of the splanchnic nerves and of the cælic axis.
7 See Dittrich, quoted by Brand, Ueber Stenosen des Pylorus, Diss. Inaug. Erlangen, 1851.
action of the gastric juice; for though ulcerations of the lower portions of the intestines are very common in other diseases, perforation is a very rare event, unless caused by the direct necrosis of the new formations of tubercle or typhoid. It is also worthy of remark that ulcers of the kind now described are, with rare exceptions, limited in their appearance to the upper part of the canal, where the solvent power of the gastric juice is still active, that of the intestines on protein substances being very inferior in this respect; and though the causes of ulceration may affect equally the whole canal, the special effects are only produced by the additional influence thus exerted.

**SYMPTOMS.**—The symptoms which are characteristic of this disease have been enumerated as pain, vomiting, haemorrhage, disturbances of the digestion, and alterations of the secretions of the stomach. The whole of these are not, however, constantly present in any single case, and there is a considerable diversity observed in their relative predominance, and in the order in which they may appear; while in a certain number, and especially in those which run a rapid course, leading to perforation, the disease may have been entirely latent until within a few hours of a fatal issue.

Pain may be regarded as the most constant of these, so much so that in its absence the diagnosis of gastric ulcer would scarcely be justified during life. It is often the earliest in its appearance, though in some recorded cases it may be preceded, for a longer or shorter period, by disturbances of the digestion, and also by pyrosis, or by excessive secretion of acid supervening immediately after meals.

There are considerable differences, however, observed in its character, intensity, duration, and mode of accession, which appear to be in some measure explicable by the extent of the ulcer, by the implication of large nerve trunks, and by the manner in which, from its position, it is affected by the movements of the stomach.

It seems, however, not unimportant to observe that the varieties of pain described, though not in all cases absolutely distinguishable, may be divided into two classes. The first of these is more or less constant, and its characters are described as those of wearing, burning, boring, but rarely (Brinton) sharp and lancinating; often confined to a very limited space at the epigastrium, but felt also in the back behind the lower dorsal and first lumbar vertebrae, and between the scapulae, in both of which latter situations, as remarked by Cruveilhier, the pain may sometimes exhibit a greater intensity than at the epigastrium. It is sometimes felt also towards the hypochondria or umbilicus, and deviations in these directions have been found by Dr. Brinton to accord with corresponding variations in the site of the ulcer. It is generally increased, and only in rarer cases relieved, by taking food. The other tends to occur in paroxysms, and is felt over a more extended area. It is of intense severity, so as sometimes to cause fainting, or even convulsions (Bamberger). The attacks, which are usually described as cardialgia, are often attended with strong abdo-
minal pulsation, probably due to a reflex paralysis of the muscular coats of the abdominal aorta.

The more constant pain, which in many cases, when exacerbations are absent, consists rather in a sense of uneasiness than of more acute suffering, seems to be directly referable to the existence of the ulcer, and to be felt with a severity proportioned to the depth to which it has extended, and especially to the implication of the peritoneal surface of the organ. The paroxysmal form is generally relieved by emptying the stomach of its contents by vomiting; and hence in many cases it is probable that it is due directly to the irritating effects of food, and to the movements of the stomach caused by its presence, and especially to distension by flatus, or to the generation of abnormal acids by fermentation, most of which causes act with greater intensity when adhesions have been contracted to surrounding parts.

These paroxysms have also been met with when large branches of nerves have been found invaded by the ulcer; and as their frequency and intensity has in some cases been found to correspond with the occurrence of haemorrhage, and also with the size of the ulcer, it is not improbable that they are in some measure connected with its extension. They are also not unfrequently caused by moral emotions, and by exposure to cold and wet, or by bodily exertion; so that, although in the majority of cases explicable by the physical condition of the stomach, there remains a certain class in which the paroxysmal character must be referred to special conditions affecting the nervous system; and some instances are recorded by Traube when during these attacks there was hyperaesthesia or anaesthesia of the cutaneous surface of the thorax, and even pain extending down the arm.

Complete intermissions of pain, sometimes extending over a considerable period, are occasionally observed; or there may be only in these intervals a slight degree of epigastric uneasiness, somewhat increased by taking food. It is a not improbable inference that the relief thus experienced may be due to periods when a cicatrization of the ulcer is taking place, as the converse condition, viz. its extension, appears to be associated with periods of aggravation.

Aggravations of the pain have been observed to precede the menstrual period, and to diminish in intensity on the establishment of the discharge.

The pain is almost invariably aggravated by pressure, and there is frequently such a degree of epigastric tenderness that the slightest pressure from the clothes, or the gentlest touch by the hand, becomes

---

2 Deutsche Klinik, 1861, p. 63.
3 Exceptional cases are recorded by Abercrombie, Henoch, Cruveilhier (Path. Anat. Livr., x., xx.), and by Miquel (Van Deen. Schmidt's Jahrbücher, ii. i. 39), where strong pressure on the front of the abdomen gave relief. In one of Cruveilhier's cases the ulcer was situated on the posterior wall, in another on the anterior surface. Miquel advances in explanation of these cases the probable hypothesis, that the mitigation thus experienced, which was particularly observed during paroxysmal attacks, may be due to the restraint thus exercised on the movements of the stomach.
4 The necessity of caution in this proceeding, to avoid rupture of the stomach, requires to be insisted upon.
DISEASES OF THE STOMACH.

unendurable. The amount of tenderness depends in some degree on the position of the ulcer, those situated on the posterior surface being less affected by manipulation. In some cases an increase of the dorsal pain has been observed to follow pressure on the epigastrium.

The effect of food is also almost invariably to bring on or to aggravate pain already existing. The period at which the pain follows its ingestion varies in different cases, and in some has been observed to depend on the site of the ulcer, those in the neighbourhood of the cardia or fundus being often more speedily followed by this symptom than where the disease is situated in more distant parts of the organ. It is seldom, however, that its appearance is long delayed; and in fact the early supervision of this symptom under these circumstances is one of the most valuable diagnostic criteria of the nature of the complaint.

When pain occurs at longer intervals after food, as after a lapse of one or two hours, it is in all probability attributable either to flatulent distension of the stomach or to excessive acidity, or in some cases to the position of the ulcer at the pyloric orifice, or in the duodenum, where the passage of the food from the stomach brings on an aggravation of the sufferings. It does not appear, however, that this difference can be depended upon with any certainty as a test of the position of the ulcer, for the symptom may be early excited, whatever the site of the disease; and, secondly, food passes out of the stomach, though in comparatively small quantities, at a very early period after its introduction.¹

Variations in the intensity of the pain have been observed to depend on the position assumed by the patient being such as to free the ulcer from contact with the contents of the stomach.² This test also is not, however, infallible, as in some cases the severity of the pain, whatever the site of the ulcer, is unaffected by posture, and in some it has even been relieved by the patient lying or pressing towards the seat of the disease.³

Though no small share in the production of the pain by food is probably due to the movements of the stomach and to the acid secretion excited by the food, yet it is found that in the majority of instances its severity is increased by indigestible and stimulating substances, and by hot liquids. Some very exceptional cases are, however, recorded, not only in which bland articles of diet have given relief—a more common occurrence—but also where stimulants, and even brandy, have sometimes mitigated severe pain.⁴

¹ See Dr. Stratton's case, before quoted; also Busch's observations on a case of duodenal fistula. Virchow's Archiv, xiv.
² First observed by Dr. Osborne, Dub. Med. Journ. xxvii. 361. Dr. Brinton says that two-thirds of the cases which he personally observed exhibited a marked influence of posture on the pain.
³ See Brinton, Ulcer of Stomach, p. 71. Also Chambers, Lond. Journ. Med. 1852, and Nasse, Schmidt's Jahrbücher, 72, who found an ulcer of the anterior surface relieved by a prone decubitus.
⁴ See a case by Mr. Travers and Dr. Farre, Med.-Chir. Trans. vol. viii. Several cases of this kind, chiefly from foreign authors, are also quoted by Miquel, loc. cit. p. 16; in
**Vomiting** stands next to pain in order of its frequency and importance. It is, however, sometimes absent throughout the whole course of the disease, while in other cases even the bl tastest articles of food are immediately rejected. Ulcers situated in the neighbourhood of the pylorus seem to be more constantly associated with this symptom than those found in other parts. In some cases it appears as a mere regurgitation of the food, without much nausea or straining; and it usually attends and sometimes terminates the paroxysmal attacks of pain.

The matters vomited vary; food is returned altered in proportion to the time during which it has remained in the stomach. Acid or neutral fluids are also brought up, sometimes in considerable quantities, either independently of food, or, when accompanying it, far exceeding the amount of fluid which has been swallowed. In other cases evidence of the destruction of adjacent organs has been found in the vomited matters, as liver structures by Miquel, and the elastic fibres of the spleen.

The sarcina ventriculi is occasionally, but not frequently, seen in the vomited matters.

**Hæmorrhage** is generally revealed by vomiting; but when smaller quantities of blood are effused, it is possible that they may often escape notice, and therefore the frequency of this symptom cannot be accurately estimated. Of larger hæmorrhages, Miquel has found fifteen instances in ninety-one cases, while Brinton thinks that they occur in about one-third of all the cases of ulcer. In a case recorded by Cruveilhier the hæmorrhage from the stomach frequently recurred at the menstrual periods, and sometimes replaced this discharge.

The characters of the blood brought up differ with the amount effused, and also with the rapidity with which it has escaped. Smaller quantities have usually a black or coffee-ground appearance, which may only appear in striae or patches on the mucus or food by which they are accompanied. Larger hæmorrhages poured out quickly from arteries of considerable size may, when vomited, still retain an alkaline reaction and arterial colour; while in other cases the blood is coagulated, and more or less blackened by the action of the gastric juice.

In some instances, however, the blood escapes by stool without being vomited. The blackened and tarry appearance which the evacuations present under these circumstances, and the distinguishing features of its origin, will be hereafter described (see Hæmorrhage). In a third class the hæmorrhage may at once prove fatal by causing syncope, without previous vomiting, and the cause of death may only be revealed post mortem by the distension of the stomach and upper part of the small intestines by large quantities of blood.

2 Sangali under Virchow, Schmidt's Jahrbücher, 1854, iv. 45.
Certain prodromata may precede or accompany the hemorrhage. The chief of these are a sense of heat, pulsation, fulness, weight or load at the epigastrium. They are not, however, commonly prominent, and are frequently unmarked, and the expulsive act is rarely preceded by any long-continued nausea. The prostration which follows excessive bleeding is sometimes very serious and alarming. The patient may be completely blanched, and the slightest movement may threaten syncope. When this condition persists without vomiting, a sedulous examination of the stools is necessary, to avoid the possibility of overlooking a loss of blood which is still proceeding, but which is only revealed by such an investigation. Blood thus escaping by stool sometimes causes diarrhoea, at others griping and colicky pains.

The digestion is liable to be influenced by various circumstances, which form very complex features in estimating the influence of this particular disease upon the functions of the stomach, and it is difficult to separate its derangements from the pain to which the mere contact of food with the surface of the ulcer gives rise. When the mucous membrane is but little affected, it may proceed almost unimpaired. The mere presence, however, of the ulcer generally brings with it conditions of derangement which are seldom without an unfavourable influence, through the effects of adhesions impairing movement, or through the direct influence of pain, or through the invasion of the nerves by the ulcer either directly impeding the secretion of the gastric juice, or giving rise to various abnormal alterations of its quality.

The evidence of this latter state is often the most prominent, and pyrosis of an acid or alkaline character may constitute for years the chief symptom present; but few cases escape without other dyspeptic derangements, and flatulence is a very common symptom. In other instances the digestion appears to be simply delayed, and to be attended throughout by a sense of epigastric load and uneasiness, and with eructations which are very liable to pass into vomiting. These symptoms are also largely influenced by the nature of the food taken; and though idiosyncracies exist, in this respect forming exceptions to the rule, they are usually aggravated by indigestible substances of all kinds.

When pyloric obstruction has been caused by an open or cicatrized ulcer, these symptoms are greatly aggravated. Nor does the healing of ulcers situated in other parts bring complete alleviation, as the contractions thence resulting may greatly interfere with the movements of the organs; and long persistent dyspepsia has been traced to this cause.

The appetite often suffers but little; frequently it is excessive and ravenous—a condition explicable in some instances by the loss sustained through vomiting, but in others probably to be referred to perverted innervation. When severe pain is present, it is often

1 See some cases by Oppolzer, Wien. Med. Woch. 1851, where raw ham agreed well.
diminished. In some of these cases patients desire to cat, but fear to
do so on account of the pain excited by food; in others a true anorexia
is present.

The appearance of the tongue is probably influenced in no small
measure by the condition of the mucous membrane of the stomach.
In many cases it presents no deviations from that of health; in others
it is more or less furred, or red and fissured. Sometimes during exacer-
bations of the disease it becomes aphthous (Abercrombie and Henoch).
It may, however, be stated, that as a general rule it offers no distinct
indications either of the presence or nature of the disease.

An excessive secretion of saliva,1 in which the sulphocyanide of
potassium is remarkably deficient (Bamberger), has been not unfre-
quently observed.

Constipation is a very constant symptom. It is probably in some
cases due in part to the vomiting; but some influence may also be
ascribed to reflex impairment of the intestinal action from the pre-

cence of the disease: in other instances, as in one by Dr. Budd,2 it is
directly due to adhesive peritonitis gluing the coats of the intestines
together, a condition which can scarcely be supposed to exist without
some degree of simultaneous muscular paralysis. In some cases the
constipation has a tendency to increase the vomiting, which then
may be relieved by acting on the bowels by means of enemata.

The general strength of the patient often suffers in an extreme
degree in the later stages of the disease. When vomiting is a promi-
nent symptom, and when haemorrhage and severe pain are superadded,
a cachetic condition is induced, which it is exceedingly difficult, if
not impossible, to distinguish, per se, from that of cancer. There is
often the same earthy tint of skin; and in females, in whom the
menstruation is disturbed, this may exist to a very marked degree.
Others have after haemorrhage the waxy look of extreme anaemia;
and the latter appearance is extremely common in young girls who
are the subjects of the disease.

Cachexia, however, except when haemorrhage is present, does not
usually occur early in the disorder; and when vomiting and haemor-
 rhage only take place at long intervals, both it and emaciation may
be absent during many years in which the disease has, in all pro-
bability, existed.3 Cases also are met with in which, though present-
ing very characteristic signs of the disease, no external appearance
of departure from sound health is observable, while in others, which
have run an almost latent course, the only symptom observed has
been a gradually progressing emaciation.4

In other instances, as was observed by Jaksch, the disease appears to
run an acute febrile course, with dull pain at the epigastrium, nausea,
and vomiting, a loaded tongue, on which aphthae are observed,
with complete anorexia. The fever is more or less continuous; the
skin is hotter than natural, and the cheeks are flushed. This con-

3 A case by Henoch, loc. cit. ii. 122. 4 Lees, Diseases of the Stomach, pp. 73, 74.
dition, of which I have observed some instances, tends especially to occur during periods when pain has been more than usually severe. Its appearance may probably be accounted for either by the supposition of an inflammatory condition of the rest of the mucous membrane of the stomach, or, in the cases in which this symptom has appeared towards the close of life, when the patients are exhausted by the duration of the complaint, it may probably often arise from some intercurrent inflammatory action, and especially from pneumonia, which is found to be a common complication. The frequency with which tuberculosis is met with in cases of the disease would also probably serve to explain the febrile reaction in such instances.

The frequency of the connexion of amenorrhea with the gastric ulcer has been treated of in the ætiology of the complaint.

The symptoms of duodenal ulcer differ but little from those which are met with when the disease occurs in the stomach.

Pain is often a less prominent feature, its absence being explained by Dr. Budd to depend on the fact that this part of the canal is subjected to less movement than the stomach. It may, however, exist with the same severity, and with all the features which have been before described; and, as in the case before quoted, it has been known to occur when the stomach is empty. It has been observed in some cases to be limited to the right hypochondrium, and to be associated with marked tenderness on pressure in the same region. In a case recorded by Mayer an excessive feeling of hunger was noticed.

Vomiting is also said by Krauss to be less frequent, and when present it is generally associated with stricture of the intestine. It sometimes occurs in connexion with attacks of cardialgia, when its explanation is probably to be found in a reflected irritation communicated to the stomach.

Hæmorrhages, revealed by vomiting or by the state of the faeces, occur in about one-third of the recorded cases; and fatal cases, when death has taken place immediately by syncope, have also been recorded.

The disease in this region also frequently appears to run a latent course, unrevealed by any symptoms beyond those of slight dyspeptic derangements, until fatal perforation suddenly occurs.

Dr. Brinton has stated that diarrhoea is common in ulceration of the duodenum, and that it thus forms a contrast with the constipation observed when the stomach is the seat of the disease. Krauss, however, who appears to have collected the largest number of cases of this disorder, regards diarrhoea as being only an exceptional symptom, and says that constipation is the rule in the duodenal, as in the gastric, ulcer.

The symptoms of perforation, both of gastric and duodenal ulcers,

---

1 See also a case by Mayer, loc. cit. 106.
2 The same fact was observed in Busch's case of duodenal fistula.
3 Cas. Broussais, Duodenite Chronique, 1825, p. 65.
4 See some cases of this nature by Dr. Budd. Also one by Dr. Murchison, Path. Soc. Trans. ix. 198.
arc almost invariably sudden in their invasion; but in a few cases probably where perforation has been gradual, they have been observed slowly to increase in intensity; and a similar course is witnessed in instances accompanied by the formation of local abscess in the cavity of the abdomen.

In the first class, however, which form much the largest number, they usually supervene after a full meal, or after some violent exertion, or after vomiting, or the effort at defecation. They are ushered in with an intense pain in the abdomen; sometimes a sensation of tearing has been described (Dahlerup); rigors have also been noticed at the outset. Severe general abdominal pain follows, which is greatly aggravated by vomiting or by severe retching. An intense degree of collapse is frequently associated with these symptoms; the face is pale and sunken, anxious, and hippocratic; the pulse small, rapid, and almost imperceptible; the limbs cold and tremulous; and death may take place suddenly at this stage from shock.

If life is prolonged, the symptoms which follow are those of general peritonitis. The abdominal muscles are at first spasmodically contracted and drawn into knots (Crisp); subsequently the abdomen becomes greatly distended from gas escaping into its cavity, and the percussion note is uniformly tympanitic. The liver is also pushed backwards, so that its dull resonance in front is replaced by a tympanitic percussion note under the ribs (Oppolzer). Respiration is entirely thoracic and sighing, the knees are drawn up on the abdomen, and the patient is afraid to speak or move through fear of increasing his sufferings; the abdomen is also intensely tender on pressure. If life is sufficiently prolonged, signs of an accumulation of fluid may be detected in the lower part of the cavity; but death usually takes place in a few hours, or at most after two or three days.

In other cases, where circumscribed abscess has formed, the signs of general peritonitis may be wanting, and those of the localised inflammation may be more or less distinct, in the form of limited pain and tenderness, associated sometimes with circumscribed enlargement, and even with a distinct fluctuating tumour. In these cases symptoms of general peritonitis may follow at later periods, owing to the escape of the contents of the abscess into the abdominal cavity. Perforation of other structures may be shown by a fistulous communication with the external surface, or by signs of empyema or pneumothorax, or by a large expectoration of puriform fluid, associated with more or less hæmoptysis, or by the physical signs of a cavity, or of circumscribed gangrenous pneumonia at the base of the lung, or, when the colon has been invaded, by the passage of undigested matter by stool soon after food has been taken, or by faecal vomiting, and a faecal odour of the breath.

1 Bouilland, Arch. de Méd. i. 534, cited by Andral. Pressure on the epigastrium, through leaning out of a window, is mentioned as a cause by Henoch.
2 Also noted by Cruveilhier.
3 This has been recorded in only one case by Abercrombic.
DISEASES OF THE STOMACH. 915

Course and Duration.—Both the course and duration of these ulcers are, as will be seen from the foregoing description, very variable. Two main classes may, however, be appropriately established; one, when the disorder is of short duration, tending either to an early cicatriziation, or to a rapidly fatal termination by perforation or hæmorrhage, and another, when the disease is of almost indefinite duration, lasting with intermissions during many years, and occasionally interrupted by severe attacks of pain, vomiting, or hæmorrhage—variations which may probably be explained by the occurrence of imperfect cicatrization alternating with renewed extension of the ulcerative process.

Prognosis.—Cruveilhier's statement, that "the simple ulcer of the stomach tends essentially to a cure," is fully confirmed by the number of cicatrices found post mortem as compared with that of open ulcers. Additional support is afforded to a hopeful prognosis by recorded cases, where, after long persistence of the symptoms of ulcer, these had subsided, and the presence of cicatrices has been revealed by autopsies made after death from other causes, and sometimes after long intervals of time. It cannot, however, be denied that the dangerous nature of the events which may occur during its course contribute to impart to the disease a character of extreme gravity.

Even the periods of comparative immunity from the more urgent symptoms by no means, in all cases, justify the conclusion that the disease is at an end, for intermissions of these followed by renewed exacerbations are not uncommon. The hope of a permanent cure diminishes also in proportion to the length of time which the disease has lasted; the cicatrization in these cases being impeded by thickening of the margins of the ulcer, by the implication of other organs, and by the inversion of the mucous membrane into the funnel-shaped excavation.

When a cure is not effected, the progress to a fatal termination is generally slow, sometimes extending through periods of many years; the patient dying finally of exhaustion and marasmus induced by the pain, vomiting, hæmorrhage, and disturbances of digestion.

In other cases, as has been before described, life may be imme-
diately cut short by hæmorrhage or perforation. The risk of the former of these accidents is not very considerable, amounting, according to the estimates of Dr. Brinton (with which those of Müller and

1 Dr. Brinton quotes cases where evidence of continuous disease had lasted in one 35 years; in two 30; three or four 20; in four or five 15; and in several 10, 7, 5, and 4 years. Dr. King Chambers has also recorded a case (Indigestions, p. 185), where the patient died of ulcer of the stomach thirty years after the first haematemesis. Other instances are given by Cruveilhier and Dr. H. Jones.

2 Cruveilhier, Archiv. Gen. 1856, p. 180. The case of the celebrated anatomist Beclard, given by Billard, De la Membrane Mucusee Gastro-Intestinale, 1825, p. 558, is an interesting example of this fact. After severe intellectual labour he suffered from pain at the stomach and vomiting; but by a careful diet, local bleeding, and counter-irritation these ameliorated, though only gradually. After his death, many years after, the cicatrix of an ulcer was found in the small curvature of his stomach.

3 N 2
Miquel pretty closely correspond), only to about 3½ to 5 per cent. of all cases.

The frequency of perforation has been stated to be open to discussion; but, under the most favourable estimates, the danger of death from this cause is considerably greater than that from hemorrhage. The prognosis, in this respect, is liable to be influenced by the age of the patient, for it has been seen that with advancing years the liability to this event is considerably diminished. The risk in the early periods of life appears also to be greater in the female than in the male sex.

Even, however, in the commonly fatal event of direct rupture of the stomach and escape of its contents into the cavity of the abdomen, life need not be absolutely despaired of, since cases have been brought forward which prove that recovery may take place even after this has ensued.¹

After the formation of an external fistula through the abdominal parietes, life in some cases seems to be prolonged without much suffering, and cases of cure by closure of the external opening have been recorded.²

Even with the completion of the process of cicatrization the cure of the patient can hardly be said to be perfect. The cicatrix by involving branches of nerves may be the source of long-continued pain, and probably also of derangements of the gastric secretion, while alterations in the shape of the organ, arising from the healing of large ulcers seated in its central portions, may often, by interfering with its movements, prove the source of permanent disturbance of the digestion. The evils resulting from contractions from the same cause of the pylorus and duodenum will be again alluded to. Nor can the risk of a renewal of the ulcerative process in the tissue of the cicatrix be lightly passed over, since many cases are recorded in which the disease has returned in its original seat, and ended in perforation or haemorrhage after the ulcer had been apparently closed, or, at least, after all the more urgent symptoms had ceased for years; a liability which induced Cruveilhier to express the opinion that both these accidents are more liable to occur “consecutively,”—i.e. by the erosion of the cicatrix,—than “primitively” during the period of the formation of the ulcer.³

¹ See a most interesting case of this nature by Dr. Hughes and Messrs. Hilton and Ray, Guy’s Hosp. Rep. 2d Series, vol. iv., of a girl in whom all the symptoms of perforation occurred, but ended in recovery. At a later period, after a meal which had greatly distended the stomach, the same patient was again attacked in a similar manner, and death ensued. At the autopsy two open ulcers were found in the stomach, one of which had perforated. There was a cicatrix of a former ulcer, and old adhesions existed between the stomach and adjacent viscera, and also between coils of the intestine, giving evidence of a previous attack of peritonitis. Miquel relates a similar case of recovery, but not verified by post-mortem examination. Another of the same kind is given by Dr. Hughes Bennett, Clin. Med. 487.

Nor can another liability be forgotten, of which proof is afforded both by the multiplicity in some cases of open ulcers, and by the frequent co-existence of these with cicatrices,—viz. that the causes inducing the disease tend to remain in operation in the same individual, and, that, though one ulcer may have healed, another may be formed and may prove fatal at a subsequent period.

Diagnosis.—The symptoms of ulcer of the stomach require to be distinguished from the severer forms of neuralgic affection, from some cases of chronic inflammatory action, from cancer of the stomach, and in some cases from colic. The distinguishing features of the affection are severe localised persistent pain, intensified in paroxysms, aggravated by food, and associated with tenderness on pressure, with vomiting, and with haemorrhage, disclosed either by vomiting or by stool.

Without the simultaneous occurrence of the greater number of these symptoms, the diagnosis of ulcer must often remain somewhat uncertain, and it is the combination now enumerated which must mainly serve as the basis of diagnosis.

Some of them, however, are more frequent than others, and localised pain aggravated by food and associated with localised tenderness is sufficient to excite the gravest suspicions of the nature of the disease.

In another class, however, persistent dyspeptic symptoms associated with extreme degrees of acidity, unaffected by food or by treatment, have proved the sole symptoms of the disorder, which has ended fatally by perforation.¹

The diagnosis from chronic catarrhal inflammation is as a rule only difficult in those cases of the latter disorder which are attended with haematemesis from congestion. The distinctive features of this form of disorder have been already described (see Chronic Catarrh, pp. 878, 884). The other forms of chronic catarrhal inflammation are rarely associated with distinct or severe gastric pain. Vomiting also is a much rarer symptom. They are, further, usually associated with more marked symptoms of dyspeptic derangement, with a more loaded tongue, and with more thirst, malaise, and pyrexia than are commonly observed in cases of ulcer.

The chief features which distinguish ulcer from neuralgic affections of the stomach have been already passed in review; it may be stated, in addition, that the aggravation of the pain by pressure, when tenderness of the muscles can be excluded, is another most important means of diagnosis. It is rarely absent, unless in cases when the ulcer is situated in the posterior wall of the stomach, and even then it can usually be elicited on deep pressure; and the exceptional cases in which the pain of ulcer has been noticed to be relieved by pressure are scarcely sufficiently numerous to invalidate a diagnosis founded on these data. The tenderness in ulcer also exists in the intervals of

¹ Abercrombie, loc. cit. 57. Henoch, iii. 122.
A SYSTEM OF MEDICINE.

the paroxysmal pain. Aggravation of the pain at the menstrual period in females is of less value, as it has been observed both in cases of neuralgic origin and also in ulcer.

The paroxysmal pain associated with the passage of gall-stones may sometimes be a cause of some difficulty in the diagnosis, particularly as it is often associated with tenderness in the right hypochondrium.

The chief points which distinguish this affection are its sudden invasion, its violence while it continues, the persistency of the vomiting, the co-existence of some enlargement of the liver and of an icteric tint of skin, the absence of haematemesis, and the immunity from epigastric tenderness, and from dyspeptic disturbances in the intervals.

The diagnosis of the site of the ulcer is sometimes aided by the effects of position in the relief of pain, and in the relative rapidity with which this symptom appears after the ingestion of food, which occurs in some cases earlier when the ulcer is seated near the cardia or in the fundus than when it is situated in the pylorus or duodenum. Pain in the back has been observed to be more severe when the ulcer is on the posterior surface. Excessive tenderness on epigastric pressure has been found associated with those situated on the anterior wall. Absolute accuracy of diagnosis of the site of a duodenal ulcer from one situated in the pylorus, except in cases when the former gives rise to jaundice from obstruction of the common bile duct, appears to be practically almost impossible.

The diagnosis of the event of perforation is one of extreme importance in relation to treatment. Unfortunately, the distinction of its early stages from attacks of colic is a question of great difficulty, as is attested by more than one recorded error in diagnosis.

When the event has been preceded by recognisable symptoms of ulcer, its characters can seldom be mistaken; but its sudden invasion, when the disorder has run a latent course, may easily be misapprehended. The chief criteria are the greater severity of the pain, and also of the collapse in cases of perforation, together with the early accession of general tenderness of the abdomen, with vomiting, and with other signs of peritonitis. Severer attacks of colic are often preceded by a history of flatulence and constipation, and by previous slighter forms of the disorder. They are also generally of more gradual invasion than is observed in the pain of perforation. Local spots of tenderness in the course of the intestines can usually also be discovered; and in their neighbourhood some variations in the percussion note are generally to be observed. In cases of perforation, on the other hand, the whole abdomen early becomes tympanitic. The difficulty of diagnosis should always induce caution in administering

1 In some cases by Osborne, loc. cit., the patient could lie on the affected side when the stomach was empty, but this position caused pain when food had been taken.

2 It is desirable to recall the rapidity with which food passes from the stomach, as showing that very little reliance can be placed on any distinction of the period at which the pain occurs.
Purgatives in cases where any doubt exists regarding the nature of the affection.

It must be recollected that pain after food may remain after cicatrization has been effected. It has been supposed under these circumstances to be due to the irregular contractions of the organ giving rise at times to spasm.

The diagnosis of perforation of the pleural cavity or of the lung must depend on the occurrence of the physical signs of pleurisy, or of the formation of cavities in the pulmonary tissue. That of perforation of the colon has been in some cases disclosed by the passage of undigested food, or by faecal vomiting.

The diagnosis of ulcer from cancer of the stomach will be considered under the head of the latter disorder.

TREATMENT.—The principles to be followed in the treatment of this affection may be briefly summarized under the following heads:—(1) Rest. (2) The cure of conditions of the stomach which cause undue acidity from fermentation or hypersecretion. (3) The relief of pain. (4) The relief of vomiting. (5) The arrest of hemorrhage. (6) The relief of constipation. (7) The treatment of perforation.

The measures indicated under the first two divisions are, in great part, regimenal and dietetic. Medicinal remedies also aid these, and are applicable to most of those subsequently named.

(1) It has been seen that many of the most urgent symptoms result from the movements of the stomach in the act of digestion; and our first indication is to reduce these, as far as possible, to a minimum amount, and to maintain the strength of the patient by the smallest quantity of the most digestible food necessary for this purpose, and especially to avoid distension of the stomach by any single large meal.¹

The same principle should be kept in mind by endeavouring to reduce, as far as possible, all waste of tissue by bodily exertion; and for this purpose complete rest should be enjoined, and the warmth of the body should be fully maintained by external clothing. Confinement to bed during all the severer exacerbations is almost indispensable.

Cruveilhier’s method of restricting the patient to a milk diet has been justified by the success which usually attends this plan. The milk should be given in small quantities, rarely exceeding a teacupful, at intervals of two hours; and in severer cases, or when vomiting is frequent, the amount must be restricted to table, dessert, or even teaspoonfuls. Long fasting is highly undesirable, and it is therefore better that the patient should be occasionally awakened in the night than

that many hours should elapse without taking nourishment. The milk is often better borne when mixed with well-boiled arrowroot or biscuit powder, since its coagulation into masses in the stomach is thereby prevented. It should not be taken too hot; but there are great differences in individual patients with respect to the temperature at which their food can be taken. Some German authorities recommend buttermilk as a substitute, when milk in its ordinary form appears to disagree; or under these circumstances it may be diluted with water, lime-water, Carrara-water, or soda-water. The latter combination is often the most agreeable to the patient. This method may often be continued for many days, or even a fortnight or three weeks, with great benefit; though at the end of this period the patients often acquire a great disrelish and even aversion to the milk diet, and some change may become necessary. It must, however, be borne in mind that occasionally an idiosyncracy appears to exist against milk, which is not digested, but gives rise to flatulence, acidity, increased pain, and even to vomiting. In the case also of elderly people milk sometimes fails to nourish, and, unless a different diet be adopted, the emaciation and loss of strength of the patient will increase. Under such circumstances recourse must be had to animal broths, made strong, but given cool, and in similarly small quantities at each meal. As the state of the patient improves, and the more urgent symptoms subside, more latitude may be permitted; but great caution should be exercised in this respect, even during periods extending over some years. Indigestible food of all kinds must be strictly forbidden, and great care must be continuously exercised to avoid undue distension of the stomach with any single meal, and the more so as the excessive appetite may often tempt the patient unduly to indulge in this respect. Hence, with the precaution that each meal should be small, food should be given at intervals of three or four hours, and milk may with advantage form a considerable proportion of the diet. Lightly-boiled eggs, when these agree, and the more digestible meats, which at first should be well stewed, may be cautiously indulged in. Bread should be eaten stale or toasted; but the use of vegetables should at first be restricted to potatoes in small quantities, and these are often replaced with advantage by macaroni. The importance of a perfect mastication of the farinaceous articles of diet, and indeed of all the food, should be strongly insisted upon. Hot liquids, and especially tea and coffee, should be almost permanently excluded, and should, when possible, be replaced by milk and water, or by cocoa made from the nibs. Malt liquors are generally found to cause flatulence, and to aggravate the pain; Dr. Brinton has, however, observed, that they sometimes agree in the case of elderly people. When stimulants appear to be required, dry sherry or pale brandy, in small quantities, and largely diluted with water, are the best that can be taken.

Sugar, since the objection to its use by Cruveilhier, has fallen into general disrepute, and it should certainly be only moderately indulged
in. It is a powerful stimulant to the mucous membrane of the stomach, and it also easily undergoes acid fermentation—properties which tend to render its use undesirable.

(2, 3.) The therapeutic measures under the second and third divisions include most of the remedies ordinarily employed in the treatment of ulcers of the stomach, and it is a question how far their action is directly excited on the disease itself, or in what measure their beneficial agency is due to their influence on the surrounding mucous membrane. The main object in the latter direction is to diminish hyperemia and its causes, and to check catarrhal action; but as these indications can scarcely be distinguished separately, it will be best to speak of individual remedies which may be employed for these purposes.

The influence of bismuth in this disorder is too well attested to need any apology for placing it among the first on the list of appropriate remedies. Its beneficial effects in catarrhal conditions of the mucous membrane have been already treated of. Whether or not it exerts any direct influence on the ulcerated surface may be open to question, but such an action would at the least not appear improbable. It appears also to exercise an influence in checking hypersecretion, and for this purpose may be advantageously combined with kino and opium, both of which possess a similar power, or with opium or morphia alone, when this is less marked. It may be administered in the form either of the subnitrate or subcarbonate suspended in mucilage. I have rarely found it necessary to administer a larger quantity than ten grains for a dose repeated four times in the twenty-four hours; but Dr. Brinton has employed larger quantities, as a scruple.

Opium is the remedy chiefly to be relied on for the relief of the pain and vomiting. The amount given should be sufficient for the more or less complete removal of the pain, and in severe cases several grains of the crude drug may often be given advantageously, in divided doses, in the course of twenty-four hours.

The utility of the salts of silver has been warmly disputed. There can be little probability that the nitrate in the small doses in which it can be administered (which should rarely, if ever, exceed half a grain to a grain) exercises an action on the surface of the ulcer similar to that which follows its application to external parts, since so large a proportion must, from the mucus present in the stomach, be immediately converted into the insoluble chloride. Its agency, however, in catarrhal affections of the stomach, and in cases where, from the pain and vomiting, there may have been great reason to suspect the presence of an ulcer, is so unquestioned, that, though standing second to bismuth as a remedy in this disease, it may be regarded as a valuable adjuvant to our resources in cases when this remedy does not appear to exercise its wonted beneficial effects, and it will sometimes be found to relieve pain after bismuth has failed.

1 See Blondlot, Exp. sur la Digestion, p. 223.
The employment of alkalies, among which may be included the bicarbonates of potash, soda, and magnesia, and lime-water, should be restricted to those cases, when, together with flatulency, there is evidence of acidity, resulting from fermentation in the food. The presence of free acid of this nature must exercise an injurious influence, both on the surface of the ulcer and on the mucous membrane of the stomach, which may be appropriately neutralised by these remedies given between meals. Under other circumstances their use is injurious, as tending, when given on an empty stomach, to excite the secretion of the gastric juice; and except as simple palliatives, they are of no value in the acidity resulting from hypersecretion, which is best controlled by the treatment before mentioned. In cases, however, where they are applicable, the use of the natural or artificial Carlsbad-water has been found advantageous.

When the severer symptoms have subsided, if there be evidence of anemia, the use of iron may be most advantageously resorted to. The neutral preparations, such as the ferrum redactum, the ferri ammon. cit. the carbonate of iron, or the mist. ferri co., are those most suitable; they should at first be given in small doses after food, and their employment is to be discontinued if pain supervene. The recommendation of Abercrombie of the ferri sulph. in combination with aloes has been endorsed by Henoch; but I confess that I regard those above mentioned as safer remedies in these cases.

Pain of a severe kind, indicating the extension of the ulcer, requires additional care in restriction of the diet, and in enforcing absolute rest. It is, as has been already stated, most effectually relieved by opium, to which, for this purpose, hydrocyanic acid is decidedly inferior. The effect of position should also be tried. Warm cataplasms and fomentations also afford relief, and a marked effect of this kind is sometimes produced by the application of a few leeches over the epigastrum, especially if the pain is in this region localised. Their number should, however, be limited to two or three, and it is not necessary or desirable to encourage free bleeding.¹

Counter-irritation does not seem desirable during the attacks of severe pain, and, in some instances, when an ulcer has appeared to have formed adhesions near the surface, the application of a blister has been followed by increased suffering; but in the intervals and during the course of the disease the use of remedies of this class has been recommended by many careful observers, and when combined with other suitable measures appear to have conduced to a cure.² Osborne recommended an issue made with caustic lime, but the least distressing counter-irritants are either mustard poultries, small blisters, not exceeding the size of a five-shilling piece, or friction with croton oil.

¹ Dr. Brinton opposed the application of leeches altogether; but the benefit that often accrues from their use, by the relief of pain, often appears to counterbalance the small loss of blood which they occasion. The cases for their employment require, however, to be judiciously selected.

² See the case of Beclard, before quoted.
DISEASES OF THE STOMACH.

Pain is also frequently alleviated by the warm bath, and the prolonged use of this remedy has been recommended both by Cruveilhier and by Andral, not only for this purpose, but also as an aid in checking vomiting. The pain of flatulent distension and spasm, though often relieved by opiates, requires occasionally, from its severity, a departure from the general principles of treatment observed in these cases. Emetics cannot be too strongly forbidden,1 but the use of warm liquids sometimes relieves the spasm and promotes the evacuation of the flatus, or even the regurgitation of the contents of the stomach, in which these attacks commonly end. The aromatic spirit of ammonia may also be used for the same purpose. Nausea and vomiting may be treated, in addition to the remedies before quoted, by ice in small quantities, and by effervescents containing hydrocyanic acid, though the latter are of less efficacy than preparations of opium. This symptom, when obstinate, requires the most extreme restriction of the diet; and it is often advantageous during some hours, or even some days, to avoid introducing any food into the stomach, and to maintain the strength of the patient by nutrient enemata given in as small a bulk as possible. Milk, beef-tea, eggs, and, if necessary, small quantities of brandy, may be given in this manner; and Dr. Brinton, on the advice of Dr. Hawkins, has also employed cod-liver oil for this purpose with beneficial results. Even opiates may thus be administered with advantage, when rejected if given by the mouth. Thirst may be quenched by slowly sucking small pieces of ice.

Vomiting appears in some cases to be maintained by a loaded condition of the bowel, and in these the administration of a purgative enema is sometimes beneficial.

Haemorrhage must be controlled by cold and by direct astringents. I have found none so dependable as the acetate of lead given in doses of three or four grains, in combination with a quarter of a grain of opium, every two or three hours. Turpentine has been recommended by Hunter, and its utility has been confirmed by Drs. Graves and Seymour. Dr. Budd thinks it more useful in cases of capillary haemorrhage than when the blood proceeds from larger vessels. The use of other remedies of this class will be further alluded to.—(See Haemorrhage.)

Ice internally may be employed with advantage for the same purpose, and this agent and also opiates are useful in checking the movements of the stomach in the effort at vomiting, by which the tendency to bleeding is necessarily aggravated. During the continuance of this symptom the most absolute rest of body must be enjoined. The diet should be restricted, as when vomiting is present. When severe collapse is threatened, stimulant enema may be given,

1 The danger of these was recognised by Schmidtmann, Summa Observationum Prax. Med. iii. 224, 395, who in addition to cases within his own experience, where they were followed by a fatal issue, quotes a case from Boerhaave, that of Admiral Wasseauer (Op. Omnia, 1738, p. 98), who died of rupture of the oesophagus from this cause.
and ether inhaled. It is important also to watch the faecal evacuation after the haematemesis has ceased.

Constipation is always to be treated with caution; an almost universal consent has proscribed mercurial preparations as injurious. When it does not nauseate or cause vomiting, there is no better laxative than castor oil; but, in the numerous instances in which its use is prevented by the intolerance of the patient, the best substitutes are aloetics and the pil. colocynthidis composita. The administration of purgatives by the mouth should, however, as far as possible, be avoided, and the action of the bowels assisted by cold or tepid enemata, in which manner also castor oil may often be beneficially employed.

When perforation is threatening or has occurred, the most absolute repose to the patient and also to the stomach is an object of primary importance. In the former case Miquel has recommended that such a position should be maintained as to leave the ulcer free from contact with the contents of the stomach. When the event has taken place, no agent appears to have any curative influence but opium, and its use must be continued for many days. The only favourable recorded terminations to this event are those where this plan was pursued. If life should fortunately be prolonged, the importance of a long-restricted diet, so as to avoid the distension of the stomach, cannot be too strongly insisted upon. Finally, patients should be warned that in intervals of comparative immunity from urgent symptoms they are still in danger of relapses; and a case by Cruveilhier,\(^1\) in which a return of the ulceration after many years of immunity followed the free exhibition of purgatives for a cerebral affection, may well awaken the question put by that distinguished author, whether these remedies were not truly the cause of the relapse, and should induce caution in all treatment, hygienic and medicinal, of patients in whom the disorder has once existed.

VII.—Cancer of the Stomach.

**Definition.**—A disease of uncertain duration, characterised by the symptoms of pain, vomiting, perversions of the secretions of the stomach, and disturbances of the appetite and digestion, and tending to a fatal termination by marasmus, cachexia, or haemorrhage; whose essential anatomical character depends on the development in the coats of the organ of a heterologous growth presenting the structural peculiarities and pathological course of cancer.

**History.**—Tumours forming in the coats of the stomach, and tending to ulcerate, have been known from very early times. Their nature, however, has only become more strictly defined by the extension of

the knowledge of pathological anatomy, which has revealed the dependence of many cases formerly described as melæna and cardialgia upon growths of this nature.¹

Ætiology.—Frequency.—The estimates of the comparative frequency of this disease in relation to all other causes of death vary between 0.6 and 2 1/2 per cent.² It appears, therefore, that the disease is less common than ulcer, but its extreme fatality places it on about the same level in respect to its frequency as a cause of death.

Regarded in relation to primary cancers in general, that of the stomach is one of the most common occurrence. Tanchou’s tables represent it as forming 25.2 per cent., Marc d’Espine’s 45 per cent., and Virchow’s 34.9 per cent. of the whole number of cancers recorded, equalling, if not exceeding, in frequency those of the uterus and mamma.

Age.—Dr. Brinton’s returns from 600 cases show that three-fourths of these occur between 40 and 70; and that the greatest number is met with between 50 and 60; though, allowing for the number of all persons living, the maximum liability is found between 60 and 70—a result very closely corresponding for the particular organ with that deduced by Dr. Walshe for the whole class of these diseases.³ It is decidedly a rare event in the earlier periods of life, but a case of congenital scirrhous of the stomach is recorded by Wilkinson;⁴ though

² The smallest number is given by Tauchou (Rech. sur le Traitement Médical des Tumeurs du Sein, Paris, 1844), founded on an aggregate of 382,551 deaths in Paris, during the years 1830–40. Virchow (Verhand. Phys.-Med. Gesell. Würzburg, vol. x. and Krankhaften Geschwulstige, vol. i.) and Brinton (loc. cit.) agree in their estimates of about one per cent.; that of the former author being based on a total of 3,380 deaths in the mortality returns of Würzburg during the years 1852–5; that of the latter on a collection of records of 8,468 post-mortem examinations in various London hospitals. Au almost similar correspondence in an average of two to two and a half per cent. is attained by Marc D’Espine (Statistique mortuaire du Canton de Genèvre pendant les années 1838–1855, Echo Médical, 1858, quoted by Lebert and Virchow,) and by Willigk (Prager Viertel-Jahresch. No. 38, 44, 50, 51); that of the former being derived from the registers of the Canton of Geneva, while that of the latter is founded on the recorded necroptic, amounting to 6,196 cases, in the hospitals at Praguo. Willigk’s per centage of the relative frequency of cancer of the stomach to other cancers agrees very closely with Virchow’s.

³ Loc. cit. 140, 151.

ordinarily, when occurring in this organ during childhood, it tends to assume the medullary form.

Sex.—The data on this head are somewhat uncertain. Brinton, from 784 cases, considered that there was an excess in the male sex in the frequency of its appearance. As other writers have, however, given very different proportions, the sexual influence cannot be considered very strong in determining or preventing the localisation of the disease in the stomach; nor does the united influence of age and sex present at all the same remarkable aetiological features as are observed in the case of gastric ulcer.

The remaining causes of the disease in this special seat are as obscure as those which determine its appearance in other parts.

Hereditary transmission appears to operate with the same uncertainty as prevails with regard to the whole class of tumours. Its influence as an occasional predisposing cause can scarcely be questioned, and the case of the Napoleon family, so often cited, is a striking illustration of this tendency.

The influence of direct irritation or inflammatory action maintained by Boerhaave and Van Swieten, and also by Broussais and Andral, and by other writers of the French school, can only have a direct influence attributable to them under circumstances of some as yet unknown constitutional predisposition. A direct effect also can scarcely be attributed to habits of spirit-drinking, or to blows, or other mechanical injuries or pressure on the epigastric region; nor even to depressing emotions, when independent of the unknown antecedent conditions, though this class of causes has frequently been observed to favour either the immediate outbreak or the more active development of the growth.

1 Brinton gives 784 cases; 440 males, 344 females.
   Louis        33  20  13
   Lebert       42  19  23
   Marc D’Espine 116  54  62
   Dittrich     159  64  95
   Willigk     169  83  86

In Dittrich’s and Willigk’s cases there was an excess in the number of females dying in the hospital. Brinton considered that the excess in the female sex was due to the greater proclivity of the generative organs in the female to become the seat of cancer.

2 Among the curiosities of this class may be mentioned cases where corrosive poisons have been followed by an outbreak of cancer: as after nitric acid, recorded by Andral, Clin. Méd. ii. 99; or arsenic, Dittrich, Prag. Viertel-Jahreschrift, xix. pp. 110, 114. The latter case may, however, be well contrasted with one quoted by Dr. Walsh, when a mass of arsenic was encapsuled in the stomach, without further apparent injury, Cancer, p. 157.

3 Comm. in Aph. Boerhaave, 1758, vol. iii. pp. 147, 150.

4 Clin. Méd. ii. 81, 60, 61.

5 Symptoms of chronic inflammatory action or dyspeptic disturbance have indeed been noticed to precede for many years the severer symptoms; but it is doubtful whether, on the one hand, these may have not been caused by a latent growth of the disease, and, on the other, how far, considering the prevalence of these symptoms in patients who do not become cancerous, any influence in the production of the disorder can be ascribed to such derangements. Beau, Gaz. des Hôpitaux, 1859, p. 390–1, says that an “idiopathic” dyspepsia may long precede cancer of the stomach. Lebert’s analysis, however, would show that in the majority of cases of cancer of the stomach the digestion has been accomplished naturally up to the period of the appearance of the disease.
What the local predisposition may be that causes the stomach with such great proportionate frequency to become the seat of this disease can only be in great measure a matter for conjecture. Virchow's argument that the organs and parts of organs which most frequently suffer from morbid growths are either those which, from their position or structure, are most exposed to or susceptible of injurious influences from external agencies, or are those whose nutritive processes are conducted under special and peculiar conditions, finds at least a basis in the case of cancer of the stomach; but it is also deserving of notice, as pointed out by Dr. Brinton in relation to this question, that the disease only very rarely commences on the surface of the mucous membrane.

Marc d'Espine's returns show an excess of mortality from cancer of the stomach in the wealthier classes. Of twenty-one cases there were fifteen rich to six poor, but these numbers appear too small to serve as the foundation of a comprehensive induction.

Bamberger states that it is most common in flabby and fat persons, but gives no further detail.

**Symptoms.**—Cases of cancer of the stomach may be divided into two distinct groups,—one in which the disease, even when attended by extensive ulceration, may run an almost latent course, and even arrive at a fatal termination, unmarked by any severer symptoms than anorexia and dyspeptic disturbances of a comparatively insignificant character, but attended by a gradually increasing emaciation and loss of strength,—and a second, when its presence excites the more formidable disturbances of pain, vomiting, and haemorrhage. A third variety, however, occasionally occurs, in which cases that have presented the features of the first-named class may towards the close assume the more distressing characters of the second. A fourth also is sometimes met with, where the pain or vomiting, which have been the first symptoms, have ceased, and the disease has advanced to a fatal termination, and where the only distinct symptom has been a steadily progressing emaciation (Abercrombie).

Cases of the first kind, though by no means rare in the history of medicine, do not form a large proportion of the whole. The absence of the more prominent symptoms may often be traced to conditions affecting either the site of the growth, the rate of its enlargement, or the depth and extent to which ulceration has proceeded, or the relation of the nerves or vessels of the stomach to the tumour.

1 Dr. Walshe's critical remarks on this question deserve the most attentive consideration, from the remarkable logical acumen with which he has handled it, loc. cit. pp. 94, 95.

3 For observations of this nature see Pemberton, Dis. of Abdominal Viscera, p. 84. Sir T. Watson, Princ. and Pract. Physic, vol. ii. Seymour, Med.-Chir. Trans. vol. xiv. Andral, Clin. Méd. ii. Cruveilhier also gives a case where the appetite and digestion were preserved, and the only symptoms were dropsey, emaciation, and pyrexia. Path. Anat. Liv. x. A very similar one is recorded by Abercrombie. Even extensive ulceration appears in some cases to have been attended by little or no vomiting, and by only comparatively slight disturbance of the digestion.
In its ordinary course the disease is usually first manifested by symptoms of dyspepsia, beginning without apparent cause in a person who has arrived at middle age, and who often has previously enjoyed good health. These may be at first very undefined, consisting of weight and uneasiness felt at the epigastrium after taking food, and followed by gaseous, acid, or insipid eruptions. The tongue in the meantime is usually found unaffected, pale, or presenting its normal appearance. Thirst is generally absent. Loss of appetite is often an early and prominent feature. The strength fails, and signs of emaciation, at first slight, become increasingly distinct. As the disease advances the epigastric uneasiness passes into pain, which is often of considerable severity. Vomiting also takes place at irregular intervals. Rare at first, and attended only with the rejection of food, or of mucus, which may be stained or mottled with streaks, specks, or flakes of rusty, sooty, or coffee-ground tint, it occurs more frequently as the disorder progresses. Flatulence and constipation become at this period prominent symptoms, and the patient is often dejected, morose, irritable, or desponding. At variable periods in the history of the case a tumour becomes perceptible in the epigastric region. In proportion as the disease is more fully declared, the epigastric pain grows severe and distressing. Vomiting is frequent, and large quantities of more or less altered blood are at times ejected. The emaciation deepens into cachexia; the skin acquires an earthy tint; diarrhoea alternates with constipation; febrile action, akin to hectic, sometimes appears towards the close, though usually this symptom is absent; dropsy, general or local, occasionally supervenes; and the patient dies exhausted after one or two years of suffering, and with an extreme degree of marasmus.

These symptoms, however, often differ considerably in their relative intensity, and also in the order of their occurrence, and appear to merit some separate consideration.

The duration of the preliminary stage is very variable, and the disturbances in the digestion may present nothing characteristic, and may even be entirely absent up to the fatal termination (Cruveilhier). Anorexia, however, though by no means constant (as the appetite is in some cases maintained to the close of life), is a very distinctive feature of the disorder. Generally it proceeds pari passu with the pain and with the increasing cachexia and debility, to which, in many cases, it stands in direct relationship. Sometimes, however, it occurs early in the disease, and appears to be quite unconnected with the latter symptom, and under these circumstances it is, according to Brinton, more marked in proportion to the youth of the patient and to the softness of the cancerous growth. There are, however, intermissions, sometimes of considerable duration, in this disrelish for food, and, instead of being lost, the appetite may be capricious or fanciful.

1 This author records a case where the anorexia was only manifested by a sudden disrelish for tobacco in a habitual smoker, but which, combined with a cachectic appearance, induced both the patient’s attendant and himself to diagnose the existence of cancer, which was shortly after verified.
According to Lebert's and Brinton's estimates, anorexia occurs sooner or later in from 78 to 85 per cent. of all cases of cancer of the stomach, and thus forms a remarkable contrast with the condition of the appetite in cases of gastric ulcer. When, however, vomiting is present, and especially when this arises from obstruction of the pylorus, the appetite may be found to be increased.

Pain is the most constant, as well as the most marked, symptom. It is frequently the first in its appearance, and is often during a long period the only evidence of the disease. At first it seldom presents the same intensity as in the later stages of the disorder, and it may then only exist as a dull aching felt in the epigastric region, or in the back. It is, however, often of intense severity, and is described as burning, tearing, or lancinating; but this latter character is not always observed. There are, not unfrequently, complete intermissions in its appearance, which may last over many days, or even weeks; in other instances, even when the pain is of great severity, it may be nearly continuous. In some cases it may occur in paroxysms of considerable severity, resembling attacks of cardialgia, or even colic, obliging the patient to double himself up for many hours, and it may occur in this manner, unattended by other symptoms, for years. These attacks are not, however, so frequent in cancer as in ulcer of the stomach, and the character and intensity of the pain are influenced by the occurrence of ulceration, by the invasion of large branches of nerves, by the position of the ulcerated tumour, and by the extent of surface affected.

In site it may either be localised, or it may extend through the whole epigastric region. It is also often felt in the back behind the scapulae and in the course of the spine. It is sometimes, especially when a tumour can be felt, associated with distinct tenderness on pressure over the site of the growth, which is more marked in proportion to the superficial character of the latter, though this symptom is not unfrequently absent.

The pain is commonly, at least in the later stages, aggravated by the ingestion of food; but in the earlier periods of the disease this relation is not so distinctly observed as in cases of ulceration, nor is the pain so commonly relieved by vomiting.

Vomiting, though less constant, and usually appearing later than

1 Lebert says that it occurs in five-sixths, and Brinton in 92 per cent. of the cases which they have collected.
2 As in a case by Sir T. Watson, where the pain was obscurely seated in the lumbar region, giving rise to the suspicion of renal calculus, but also resembling lumbago.
3 Authorities are divided in their statements regarding this character of the pain. Bamberger, Lebert, and Brinton speak of it as being frequent; Walsh, Andral, Henoch, though affirming its occasional occurrence, deny its comparative frequency.
4 The case of the first Napoleon is an instance of this. One presenting very similar characters has come under my own observation.
5 As in a case by Sir T. Watson.
6 Brinton says that he has observed scapular pain in cases of cancer of the cardia, and pain in the lower dorsal and lumbar region, when the growth has been found on the posterior surface of the stomach.
pain, is, however, a symptom of great frequency, being recorded, according to Brinton, in 87.4 per cent. of all cases.

It is most frequent when there is ulceration of the surface, or obstruction of the orifices by the tumour; but that it does not depend exclusively on either of these conditions is shown by its absence in some cases where they have both been found, and by its presence in others in early stages of this disease, and when neither exist.

Its appearance under the latter circumstances is probably due to the direct irritation of the excito-motor nerves of the organ by the progress of the growth, and to the same influence must be attributed its occurrence in those cases when it has been excited by pressure on the tumour (Lebert).

The period at which it follows eating is generally influenced by the position of the cancer. When the cardia is obstructed, the food is usually rejected immediately after deglutition, unless the return is delayed by dilatation of the oesophagus. When the pylorus is the seat of the disease, food may be retained for some time before it is returned.

Occasionally, however, vomiting occurs when the stomach is empty, and this is sometimes observed in the morning, when mucus is usually brought up—a symptom possibly referable to co-existent gastric catarrh.

Its frequency usually increases with the progress of the disease, but long intermissions between the attacks are common in all stages. The intervals also tend to become longer when dilatation of the stomach has ensued in consequence of obstruction of the pylorus, but when vomiting occurs under these circumstances, enormous quantities of acid and fermenting food are rejected from the stomach.

In some cases vomiting, which has been frequent in the earlier stages, may almost entirely cease towards its close, a change which has been occasionally traced to the pyloric orifice again becoming opened by ulceration.

The matters vomited vary. Mucus has already been alluded to, and the ejection of an acid fluid apparently derived from hypersecretion is not very uncommon. When there is an obstruction at the cardia, the food is returned but little altered, and merely macerated and covered with a layer of mucus. When the pylorus is obstructed, food undergoes the changes before noticed, and sarcinae and torulæ are often found in the yeasty scum which forms on the surface. In fact, though sarcinae occur in the matters vomited in a great number of

1 Lebert. See also a case by Dittrich, loc. cit. p. 114, where there was almost complete scirrhous degeneration of the coats of the whole organ, and yet vomiting was absent.

2 The act of vomiting does not appear to be determined by the position of the tumour, independently of the obstructions to which it may give rise. See Lebert, p. 505.

3 Golding Bird states that in a case of scirrhus of the pylorus, where the patient vomited several pints of fluid in the twenty-four hours, he found a "quantity of free hydrochloric acid, equal in each pint to 22 grammes of pharmaceutical acid, in addition to a considerable quantity of some organic acid (lactic?), sufficient to neutralise nearly 7 grains of pure potash; at another time the hydrochloric acid nearly disappeared, and the quantities of organic acid in each pint required for saturation nearly 17 grains of the alkali." Urinary Deposits, 1857, p. 162.
Diseases of the Stomach.

931

Stomach affections, their presence is more frequently observed in cases of cancer of the pylorus than in any other single disease to which the organ is liable. Cancer cells, also, are said to have been met with in the ejected matters, but the cases in which their distinctive features can be recognised must be extremely rare.\(^1\) When sloughing action is taking place in the cancer, the vomited matters and the eructations may be offensive, but this is in some measure prevented by the antiseptic action of the gastric juice.

Hicough sometimes forms a very distressing symptom, which, however, usually only appears with any severity towards the close of these cases.\(^2\)

Hæmorrhage to a greater or less degree occurs, according to the statements of Lebert and Brinton, in nearly one-half of the recorded cases of this disease. It may be divided into two classes; slight, when only small amounts of rusty, sooty, or chocolate-tinted specks appear in the matters vomited—and larger losses of blood, in which pints may be ejected.

The former class is more frequent in cancer than in ulcer, since, in addition to the congested condition of the mucous membrane surrounding the tumour, in which varicose veins have sometimes been observed (Andral), the capillary vessels on the surface of the tumours are liable to bleed, a tendency especially noticed in fungating excrescences.\(^3\)

This form usually appears in the early stages of the disorder, while the larger hæmorrhages are usually associated with rapid sloughing destructive processes, and, in contrast to the other variety, they are less frequent in cancerous than in simple ulcerative disease. The symptoms of the larger hæmorrhages are similar to those observed during the progress of simple ulcer; and in these also the blood may escape by stool, and may give rise to melæna and diarrhœa.

The discovery of a tumour forms one of the most important elements in the recognition of the nature of the disease. From the returns of Brinton and Lebert, it may be felt in from 70 to 80 per cent. of all cases observed, and, even when not distinctly perceptible, there is often an induration associated with dulness of percussion note over some portion of the regions occupied by the stomach. The position of the tumour necessarily influences the facility with which it is detected by physical examination, and those in the cardia or in the posterior wall may occasionally elude observation.

The period at which it is felt is usually when other symptoms have existed for some time; but this, again, depends in great measure on the position in which it is developed. Its site is usually at

---

1 See ante.
2 Bamberger has observed that it is not caused by implication of the diaphragm, but is more often connected with extension of the growth to the peritoneal surface of the stomach.
3 Hence these rusty coffee-ground vomitings, though common in both disorders, were regarded before the time of Cruveilhier (who showed that they also took place in ulcer) as peculiarly characteristic of cancer of the stomach.
the epigastric region, or (from the comparative frequency with which the pylorus is affected) in the right hypochondrium. Brinton states, that in the female sex it may be found in the umbilical region in nearly two-thirds of all cases in which it is discoverable—a peculiarity due, in a great measure, to the effects of the compression of the lower part of the thorax by stays. Similar displacements, common to both sexes, may be due to the weight of the tumour dragging down the pyloric end of the stomach, when this is not retained by adhesions in its original site. The tumour feels hard and irregular to the hand, especially when it is large and situated near the anterior surface; it is generally immovable by manipulation, but alters its position through distension of the stomach by food, or by gradually increasing dilatation of the viscus. Sometimes it may disappear entirely for many days, either from the twisting of the stomach upon its axis, by which the pylorus is brought below the liver, or from its being covered by a distended colon. In some cases, Brinton thinks that its complete disappearance may be due to sloughing and destruction of the growth. Pulsation in the tumour is not uncommonly observed, due probably, in most cases, to an impulse derived from the abdominal aorta. Instead of a circumscribed mass, the whole epigastric region may be hard, prominent, and resisting, and, in some cases, the form of portions of the stomach may become prominent through the abdominal wall—a condition which usually depends on extensive infiltration of the coats of the stomach by the cancerous growth. In these cases the percussion note, instead of being absolutely dull, may have a muffled tympanitic resonance; a peculiar tinkling sound has also sometimes been heard when liquids are swallowed, arising from the fall of the fluid into the tense cavity (Bamberger).

The signs of contraction or distension of the stomach consequent upon pyloric or cardiac stenosis will be given under the head of these affections.

The tongue presents but few characteristic features. Its appearance is not necessarily affected by the cancer, and the varieties of fur, aphthae, &c. occasionally observed, depend more on the general condition of the patient, and especially on the co-existence or absence of a catarrhal condition of the mucous membrane. An excessive salivation with characters similar to those observed in ulcer has been sometimes noticed.

The cachexia in cancer of the stomach very frequently presents the most characteristic features of this disease. It sometimes appears early in the disorder, though its progress is usually proportioned to the severity of the vomiting, haemorrhage, pain, and disturbances of digestion. In the early stages, however, and even sometimes at an advanced period, there may be very little external evidence of disturbance of health.

When the cachexia becomes marked, the face is pale and sunken, with deepening of the naso-labial wrinkles. The expression is

1 Louis, Mem. Anat. Path. 130, quoted by Dr. Walshe.
DISEASES OF THE STOMACH.

anxious and careworn, or indicative of pain. The skin acquires an opaque earthy tint, which is equally marked in fair as in dark-complexioned people; in other cases, and particularly when hæmorrhage has occurred, it has the waxy look of extreme anæmia. It is often dry and rough from the desquamation of the cuticle and from the want of perspiration. Jaundice or a straw-coloured icteroid tint of skin are not uncommon. The lighter shades of jaundice are rather more frequent; the severer cases depend on pressure by the growth in the stomach on the common bile duct, or on secondary formations in the liver.

Edema often appears towards the close of the complaint, arising either from the general hydæmia, or limited to one of the lower extremities though venous obstruction from thrombosis. Ascites is also occasionally, but not constantly, observed; its occurrence depends either on the pressure exercised by the tumour on the portal vein, or on cancerous formations in the peritoneum, of which latter cause the most frequent examples are afforded, in proportion to their number, by the extensions of the colloid variety. Obstructions of the arterial circulation either by thrombosis or embolism are also occasionally observed; they then give rise to intense pain in the limb affected, with burning or cramp-like sensations, and sometimes to great temporary hyperæsthesia of the skin, which, at a later period, are followed by gangrene of the part below the seat of obstruction.

Febrile reaction is the exception rather than the rule, but it is sometimes very distinctly marked, and especially towards the close of the complaint. Its occurrence is frequently due to some secondary inflammatory action, among which pneumonia, associated either with cancerous deposits in the lung, or of the hypostatic variety, is one of the most frequent causes.

Emaciation and loss of strength usually progress rapidly from the first onset of the severer symptoms, though occasionally the nutrition and general vigour are maintained for a year or eighteen months (Lebert). In many cases, however, these symptoms are among the most prominent present; and there are few in which, towards the close, marasmus does not form a very marked feature; while in others, even at the commencement, and while the other symptoms are still obscure, the presence of these signs may, as has been before noticed, form valuable indications of the nature of the disease.

The Duration of the disease, regarded from the origin of the cancerous growth, is very indefinite; in fact, it appears impossible in all cases to fix the period of its commencement. The length of time during which some patients have suffered from even severe pain (as in the case of Napoleon, in whom this symptom occurred at intervals for nine years before his death—Abercrombie) points to the probability that the disease may occasionally persist long, without much disturbance of the general health, or of the functions of the stomach. Ordinarily this period of comparative latency rarely extends beyond two
or three months, though it has been known to last for a year and a half (Lebert).

The average duration is estimated by Dr. Brinton, from 198 cases, as amounting to 12\frac{1}{2} months, which corresponds pretty closely with the results obtained from smaller numbers by Lebert and Valleix. The minimum course which I can find recorded is one of four months (Valleix). The longest period which has been known to elapse from the first distinctive symptom to a fatal termination has been three years and a half.

Prognosis.—The termination has been invariably fatal: only very untrustworthy evidence has been afforded of the cure of the growth by enucleation and cicatrization; and evidences derived from cicatrices are untrustworthy, as we can never exclude the possibility of their having resulted from chronic ulcer (which has been shown to be a more common disease than cancer); nor can the same probability in favour of their origin be denied in those instances where cancer and cicatrices have been found co-existent in the same stomach.

Cancer, it is known, possesses the destructive peculiarity, that it is never circumscribed, but that the tissue around its margin is constantly found presenting more or less evident perversions of development with structures analogous to those of the morbid growth. In the presence, therefore, of the direct clinical experience which the course of the disease constantly affords us, and owing to the fallacious resemblance between its symptoms and those of ulcer, the evidence of the possibility of its cure must be established by more direct proof than has hitherto been furnished, or than the circumstances attending its formation in this position appear capable of affording, before this can be admitted, even on hypothetical grounds, to alleviate in any way the gloomy prognosis to which its recognition must always give rise.

The probability of a rapid course is determined by the severity of the vomiting and haemorrhage. Lebert considers early vomiting an unfavourable symptom. Cases exhibiting it have frequently terminated fatally in from four to six months.

Pathology.—The pathology of the disease will only be treated of in this place in relation to special anatomical peculiarities affecting the organ.

The growth occurs in all the known forms assumed by cancer, in the order of frequency here enumerated: scirrhous; medullary (and combinations of these); colloid, either simple or combined with either of the above; villous; and melanoid. Of these, scirrhous is found in nearly three-fourths of the whole number,\(^1\) but it is seldom unattended by softer portions on the surface or margins, which approximate in their structure and character to the medullary type.

\(^1\) Brinton, from 180 cases.
DISEASES OF THE STOMACH.

The seat of the cancer is, in the majority of cases, in the pyloric region. The cardia, from Brinton's and Lebert's returns, only appears to suffer in about 10 per cent. of all cases. Extensions beyond the pylorus to the duodenum are extremely rare; but when the pylorus is affected, the cancer usually extends around the whole circumference of the valve, and thence invades the smaller curvature. When the cardia is affected, the growth is generally, but not constantly, found to extend into the lower part of the esophagus. The proportion of all cases in which the orifices taken collectively are affected amounts to 71 per cent.; an excess in these parts which, as Brinton has pointed out, is considerably greater than that observed in cases of simple ulcers.

Cases where large tracts of the stomach are invaded are usually those where the cancer is of the colloid variety, but it is occasionally noticed in other forms.

The growth, when of the scirrhous or medullary forms, almost invariably takes its origin in the submucous tissue. It has been found, however, by Dittrich, commencing in the subserous cellular tissue. The development of the colloid form will be more particularly alluded to hereafter.

The special forms are each connected with some anatomical peculiarities, which require a separate description.

Scirrhous of the stomach presents the same contracting, indurating characters that distinguish the growth in other parts. Commencing, as just stated, in the submucous tissue, it thence extends in about equal degrees into the mucus membrane, and also into the muscular coats. The invasion of the mucus membrane is frequently marked by striated radiating lines of a cicatricial appearance, attended with destruction and atrophy of the glandular textures and induration of this coat, and sometimes by retractions and depressions of portions of the as yet unbroken surface. The true mucus structure (viz. the glands and villi), however, often resists, during a long period, the cancerous encroachment, although the membrane early becomes fixed and immoveable upon the submucous tissue.

Through the character of the growth, in which, as elsewhere, the fibrous stroma greatly predominates over the cellular elements, the parts affected by it become converted into a firm, unyielding mass, in which all their distinctive features are lost. When large tracts are thus affected, the disease may at first sight present a great resemblance to fibrous thickening, or to hypertrophy of the coats of the organ.

1 Of 360 cases Brinton found that this was affected in 60 per cent. Lebert 34 times in 57 cases.
2 Cases in which this has occurred have been recorded both by Lebert and by Brinton.
3 Brinton in 360 cases has found 13 in which the whole stomach was found thus degenerated.
5 In some of these cases this author has observed a scirrhous degeneration of this layer, together with a medullary growth in the submucous tissue, the intervening muscular coat having been unaffected.
6 The diagnosis between these two alterations is not always an easy one, since, as in
The invasion of the muscular tissue by the growth takes place, as pointed out by Rokitanski, in the intermuscular septa, which form meshes inclosing spaces containing unaffected muscular fibre. The portions thus included present a reddish or a semi-transparent appearance, and their histological elements are at first greatly enlarged, but subsequently degenerate into the cancer structures.

The effect of these changes is to produce great contraction of the parts in which they occur. Either at the pylorus or cardia the immediate result is an extreme narrowing of their openings, which is often heightened by irregular masses protruding at the surface, and by poly-poid vegetations, which, though less common than in the medullary variety, sometimes accompany scirrhous cancer.

When large tracts of the coats are thus invaded, the stomach may be externally shrunken and contracted, so as to resemble a fowl's gizzard in appearance, with dense inflexible walls, which may even attain the thickness of an inch. The small curvature may be so shortened as to bring the pylorus and cardia into close proximity, and the inner surfaces of the interior and posterior walls may be almost completely in contact.

*Medullary cancer*, commencing in the same tissues as the scirrhous variety, appears usually in the form of nodules, in masses of varying degrees of softness, and of a cerebriform appearance; more rarely it occurs as an infiltration of the different coats.

Though the peritoneum suffers with less frequency, the mucous membrane is invaded with greater rapidity by medullary than by scirrhous cancer. The nodules, when seen on the external surface, present, with the exception of their softness and cerebriform appearance, very few peculiarities. In some cases the growth on the mucous membrane tends to form large fungating excrescences, in which an exaggeration of the villous type is observable. These constitute the varieties of the so-called villous cancer, which may sometimes form large tumours, covered thickly with the hypertrophied villi.

Other parts affected by scirrhous, large tracts of tissue may often be found presenting nothing but a dense fibrous structure, and devoid of the cell structures which are usually found in the more open meshes of the stroma, though these, as pointed out by Rokitanski, can usually be found at the margins of the growth. In addition to the cancerous character of the margin, the scirrhous growth is also distinguished by its affecting all the coats equally, by their fusion into a uniform mass of pearly whiteness and presenting the gristly cartilaginous texture characteristic of this form, by the inmoveability, except at the earliest stages, of the mucous membrane upon the tissues beneath, and by the destruction of the normal appearances of the muscular layer. Two cases exhibiting the contrast of these forms are recorded by Dr. Wilks, Path. Soc. Trans. x. 130, xiii. 83.

1 As in a specimen cited by Dr. Walshe.
2 Dittrich. In one such case the mucous membrane was found smooth and shining, as if from the effects of attrition; but later it may become the seat of ulcerations hereafter to be described.
3 Their structure can be very well seen when examined under water. Each villus contains a loop of vessels, and the larger ones are usually filled with cancer cells. The delicacy of the structure of the capillary walls, which are often only covered by a single layer of epithelium, and the softness of the whole growth, together with its extreme vascularity, render this variety a dangerous source of haemorrhage.
The melanoid form is very rarely observed. In some cases it appears as small scattered nodules in or under the mucous membrane, which present the ordinary characters of medullary cancer, with the exception that their cell structures are loaded with melanin pigment.

The colloid or gum cancer has its most frequent seat in the stomach, but even here it is not of comparatively frequent occurrence. Its site of origin appears to be rather more doubtful than is the case with the other growths before alluded to. Some authors state that it begins in the submucous tissue, others in the subserous. My own opinion, which I would however state with some hesitation, is that this variety of "cancer" is essentially of glandular origin, and akin to those forms of epithelioma of the skin described by Remak, which commence with heterologous extension of the sebaceous and sudoriparous glands into the deeper structures.

It is possible that, when apparently commencing in the deeper coats, this growth may, under such circumstances, take origin in the little glandular masses which occasionally are found in these parts, and having no connexion with the rest of the mucous membrane, and of which I have seen some examples. However originating, this form of cancer tends to spread over large surfaces of the mucous membrane, which is thus greatly thickened, and has its normal texture converted into a reticular structure, with spaces filled with "colloid" material.

1 Only three times in 180 cases, Brinton; once in 160 cases, Dittrich. In Dittrich's case it was coincident with a general dissemination of melanoid tumours throughout the body.

2 In 180 cases of Dr. Brinton's colloid was found 17 times. In 160 of Dittrich's it only occurred in 11 specimens, and in three only of these was it uncombined with either scirrhous or medullary growths.

3 Deutsche Klinik, 1854, p. 170 et seq.

4 De must state, that since my attention has been devoted to this question I have only had an opportunity within the past four years of examining one recent specimen, in which, however, the glandular origin was most distinct; and my observation on preparations preserved in spirit has, though not conclusive, tended to confirm this view. In the former case there was a distinct colloid mass obstructing the pylorus, unassociated with any other form of cancer in the stomach, though attended with many polypoid growths from the mucous membrane. Two points of great interest in connexion with it were the association with an ordinary epithelioma of the lower third of the oesophagus, which did not show traces of glandular origin, and which was attended by secondary epithelioma of the mediastinal lymphatics; while in the retroperitoneal lymphatic glands, which lay immediately below the diaphragm (and had probably therefore been infected directly from the stomach), I found distinct masses of a medullary character. I think it very possible that the secreting glands of the stomach may undergo this abnormal development in cases where the primary disease has been a scirrhous or medullary growth of the submucous tissue, but I doubt whether any direct metamorphosis can take place from either scirrhous or medullary cancer into the colloid variety. A glandular tumour of the pylorus having a structure very similar to what I observed in the case of colloid just quoted, is figured by Dr. Hughes Bennett, Clin. Lect. 1865, p. 495. Its structure is, however, described as thickened, indurated, and white.

5 These are mentioned by Rokitansky; the largest growth of this kind which I can find recorded is by Loeschner and Lamb, Berichte aus dem Franz Joseph Kinderspital. That glandular growths may assume all the characters of "malignant" structures is shown by Remak's observations above quoted, as well as by a remarkable case of Billroth's of a tumour of this nature in the testicle (Virch. Archiv, viii.). The best illustration of this form of cancer is to be found in Cruveilhier's Path. Anat. Liv. x.
Its tendency to invade deeper tissues is also very considerable, and it frequently extends to the peritoneal surface, and thence to the omentum.

In their subsequent course all cancers of the stomach have certain characters in common, marked only by minor shades of variation dependent on their peculiarities of growth.

Changes in the form of the stomach from the contraction of scirrhous have been already alluded to. Diminution in the size of the organ may also occur from obstruction of the cardiac orifice. Dilatation is a very common effect of obstruction of the pyloric orifice; and it is sometimes attended with thickening, at others with thinning of the coats. Thickening when present usually predominates in the muscular layers, which then undergo a true hypertrophy. The size attained under these circumstances by the organ is sometimes such as to fill the whole abdominal cavity, and to extend even to the pubes.

Adhesions are very common to adjacent viscera when the cancer has extended through the peritoneal coat. The most common of these are to the liver, pancreas, omentum, spleen, or diaphragm, or to the abdominal wall.

Displacements, unless prevented by adhesions to neighbouring viscera, may be caused by the weight of the tumour dragging the stomach into the lower portions of the abdomen; and under these circumstances it may become fixed by new adhesions in abnormal situations, and the pyloric portion may be found in the right iliac fossa, or even in the pelvis, adhering to the intestines, uterus, ovaries, or bladder.

Ulceration is common to all varieties of cancer. It is most marked in the softer medullary forms, when it often takes on the form of sloughing, through which process large masses may sometimes be thrown off, leaving irregularities in the substance of the cancer. The same condition also occurs, but to a less extent, in scirrhous. In colloid, on the other hand, it is seldom observed, and the ulcerative process, if so it can be called in this variety, consists of the rupture of the larger spaces, which thus give rise to a series of pits or depressions on the surface. The more rapid and extensive necrotic processes are sometimes a source of dangerous haemorrhage.

The ulcers thus resulting are almost invariably distinguishable by their thickened, ragged edge, which is infiltrated and swollen by the morbid growth, and around which warty or polypoid excrescences are often formed, and also by the presence of cancer structures in their floor. Occasionally such large masses of the growth are thrown off, as to have led to the idea that the morbid structure might possibly be eliminated in this manner; but evidence of a cure thus occurring is very defective, and, although cicatricial formation is sometimes found proceeding in one part, it is usually found that the cancer structures are extending in another. In some cases this sloughing action appears, however, to have restored the patency of
the pyloric and cardiac orifices, after these had been previously obstructed by the growth.

The extension of the cancer through the peritoneal coat is attended with various consequences. Adhesions to neighbouring organs, and implications of the omentum in the cancerous growth, which are most common in cases of colloid, have been already alluded to.

General peritonitis has sometimes been observed without rupture of the stomach. Partial peritonitis taking place in the same manner is, however, more common.

Perforation, leading to a free opening between the interior of the stomach and the cavity of the peritoneum, is less frequent in cancer than in ulcer of the stomach. The data as to the absolute frequency of this event in the latter disease are, however, not sufficiently certain to allow of an absolute comparison. 2

Adhesions to adjacent organs may, however, lead to the invasion of these by the cancer, as is observed in the case of the liver, pancreas, spleen, and the lumbar vertebrae, or to fistulous communications formed between the stomach and other parts. Gastro-colic fistula has been already stated to be much more frequent in cancer than in ulcer, while the converse proposition holds true with regard to gastro-cutaneous fistula. 3

Perforation of other portions of the intestines has also been noticed, as into the ileum; and in other cases the growth extends through the diaphragm into the lungs.

The mucous membrane of the stomach in parts not invaded by cancer presents little that is characteristic. Evidences, however, of inflammatory action, sometimes existing in an acute form, are occasionally met with, and still more frequently there are seen signs of chronic forms of this process in thickenings and ash-grey pigmentation, with fatty degeneration of the glandular structures. In other cases, again, no deviations from the normal appearance and structure can be found.

The associated pathology of cancer of the stomach may be conveniently considered under the heads of the relation of the growth to similar structures occurring in other parts, and of accidental complications and secondary lesions not associated with the presence of cancerous formation.

The disease in the stomach, unless when propagated by continuity from other parts, is almost invariably primary. 5 Secondary affec-

1 Dittrich, loc. cit.
2 Dr. Brinton has estimated the frequency of perforation in cancer as occurring in rather more than four per cent. In four of his cases the contents of the stomach were effused into a limited sac bounded by the peritoneum.
3 See note, p. 901.
4 Brinton, loc. cit. A remarkable case of this nature, which has its parallel among the secondary consequences of simple ulcer, is recorded by Dittrich, Prager Viertel-Jahresch. xix. 112, where a fistulous opening was established between the stomach and duodenum after the pyloric opening had been obstructed by the cancerous growth.
5 Walsh, loc. cit. 279. It may occur among the phenomena of simultaneous multiple developments of the growth, and under these circumstances has been found to co-exist with similar disease in the ovaries and uterus. An almost unique case has been recorded by Cohnheim (Virch. Archiv, xxxviii. p. 142), when cancer was found in the stomach
The non-cancerous secondary lesions may be also briefly dismissed, as they offer but few peculiarities in connexion with the special organ in question. The occurrence of peritonitis, independently of rupture of the stomach, has been already alluded to. It appears, from the observations of Dittrich, to be sometimes of a septic character, and to be occasionally associated with pleurisy and pericarditis, due probably to a similar mode of origin. "Retrograde tubercle" was found in the lungs in most of Dittrich's cases. This author only mentions five instances of catarrhal pneumonia as a complication; but it is probable, from the statements of numerous other writers (though precise data are wanting), that a low inflammation of this type is exceedingly common, and frequently proves the immediate cause of the fatal issue. Among the other secondary affections may be mentioned coagulation of the blood in the veins of the extremities, with the phenomena of phlegmasia dolens, or in the sinuses of the dura mater. Spontaneous coagulation in the arteries is a less frequent occurrence. Its consequences have been already alluded to.

Ulcerations of a non-cancerous nature in the rectum and colon were noted twenty-five times by Dittrich, and endocarditis was observed in five instances.

The blood suffers markedly in its composition, especially when there is much vomiting, and still more so when there is haemorrhage. The anaemia and waxy pallor of the complexion are largely explicable by these events; but that the interference with digestion and assimilation may take place at an earlier stage is shown by cachexia occurring, in a certain number of cases, independently of these events. Analyses of the blood have chiefly been directed to the former class, secondarily to a similar affection of the mamma. The liver and the axillary and cervical lymphatics were also implicated.

1 These are found in about half of the cases of cancer of the stomach. The liver suffers in 25.6% per cent. of all cases (Brinton, Dittrich). In 160 cases given by Dittrich, the liver was affected 43 times; the peritoneum 22; the lungs 9; the rectum 2; and the ovary once. Brinton says that the lungs were affected in 8.4% per cent., and the gastro-lymphatic glands in 25.4% per cent., of 251 cases. Dittrich says of the latter, that it is only those in immediate proximity to the stomach which ordinarily suffer. Henoch, loc. cit. ii. 162, says that cancerous glands above the clavicle may sometimes aid in the diagnosis. Dr. Handfield Jones, loc. cit. 169, has given a case where the glands behind the stomach thus secondarily implicated contained columnar epithelium.

2 Dr. Walshe says that he has never known the lungs to suffer in this manner without implication of the liver.

3 In some cases the disease appears to spread by dissemination or contact, without adhesion, as in a case of Sir R. Carswell's, cited by Dr. Walshe, loc. cit. p. 282, where a cancerous tumour existed in the anterior abdominal wall, over, but otherwise unconnected with, a similar formation in the pylorus; and an illustration of a similar and very extensive process of dissemination over the peritoneal surface is given by Virchow, Krankhaften Geschwülste, i. 54.

4 Nine times in 160 cases, Dittrich.

5 Dittrich, loc. cit.

6 Twice in 160 cases, Dittrich.
and show, as might be expected, a diminution in the number of the blood corpuscles, and also of the total amount of solids in the serum, while the proportions of fibrine have varied, being sometimes in excess of, and at others below, the normal standard.¹

**Diagnosis.**—Cases of cancer of the stomach may be, as has been before stated, divided into two classes—one when the disorder runs an almost latent course, and is revealed only by failure of health and strength, by obscure dyspeptic symptoms, and by anorexia; another when it gives rise to either pain, vomiting, and hemorrhage, singly or conjointly, and in which, at some period, a tumour can be recognised. The former of these classes is with great difficulty distinguished from cases of atonic dyspepsia, and from some of chronic catarrh. The latter may be confounded with neuralgic conditions of the stomach, with colic, or with gastric ulcer.

It may be stated that the discovery of tumour distinctly situated in the stomach affords the only positive ground for the diagnosis of cancer from some other diseases of the organ. This, however, is not early apparent, and it may at times disappear, and the probability of the cancerous nature of the disease must then rest upon other data, which relatively are only of comparative value.

1. The diagnosis of the first class has been already alluded to (see Atonic Dyspepsia). The ætiological conditions under which the symptoms originate are of extreme importance in estimating the nature of the disorder. If such a condition should appear without manifest cause after the age of thirty-five or forty, it is sufficient to excite suspicions of its real nature, especially if loss of appetite form a prominent feature. The addition of vomiting to the above, even if unaccompanied by pain, when alcoholic excesses, albuminuria, or cirrhosis of the liver can be excluded, would add additional gravity to the suspicions entertained, since both atomic dyspepsia and simple chronic catarrh are rarely associated with this symptom, except (in the case of the latter) under some of these attendant circumstances.

2. In cases where pain forms a prominent feature, unaccompanied by vomiting, by marked disturbance of the digestion, or by haemorrhage, and when no tumour can be discovered, the diagnosis from purely neuralgic conditions must also mainly depend on ætiological circumstances, since the characters of the pain in both these classes of disease bear a great similarity to one another, being in both usually unaggravated by food, and not associated with tenderness on pressure. Sex is one of the most important of these; sex and age collectively may, in cases where the combination occurs in a male past middle life, be of great importance, for neuralgic pains of the stomach are rare under these circumstances, being most common in females at the earlier periods of life. In the female sex these conditions afford less assistance. When the climacteric period is past,

¹ Andral et Gavarret, Rech. sur la Composition du Sang, p. 238.
and the hysterical diathesis can be excluded, there may, under such circumstances, be some grounds of suspicion, but certainty can rarely be attained without some of the concomitant phenomena before alluded to.\(^1\)

3. A third class, of gradual and progressive emaciation, without distinct causes of marasmus, occurring at middle life, though unattended by any distinct stomach symptoms, should also engage attention. The manner in which cancer of the stomach can thus profoundly impair the nutritive processes, though completely unexplained,\(^2\) has nevertheless been distinctly recognised.

4. In the absence of a tumour, the diagnosis of cancer from \textit{ulcer} of the stomach is sometimes a question of difficulty. In the majority of such cases the diagnosis is rather a balance of probabilities than a question of absolute certainty, which, however, may be attained with a greater or less accuracy in a certain proportion of instances.

Common to both diseases are the symptoms of pain, vomiting, haemorrhage, and cachexia, and disturbances of digestion and of the secretions of the stomach, but they appear in a different manner, and at different periods of the two disorders.

The circumstances influencing the diagnosis may be briefly contrasted as follows:

\textit{Ætiology}.—Ulcer is more common at the earlier periods of life, and especially so in the female sex: cancer is almost limited to the later periods of life, and its appearance is comparatively uninfluenced by sexual conditions. The pain frequently presents in both disorders a paroxysmal character, but in cases of cancer it is usually more continuous, is less influenced by food, and is less frequently relieved by vomiting. The specific character of the pain affords no positive data for distinction in either disease.

\textit{Tenderness on pressure} is most common in earlier stages of ulcer. It is rarer in a localised form in cancer until a tumour has appeared, and even under these circumstances it is less distinct. The position of either disease in the stomach necessarily influences the diagnosis in this respect.

\textit{Hæmorrhage} is, on the whole, rather more frequent in cancer than ulcer, but the amount of blood effused varies considerably in the two disorders. Large hæmorrhages are much the most frequent in ulcer,\(^3\) while smaller hæmorrhages of coffee-ground or sooty matter mixed with mucus are most common in cancer. Hæmorrhages in the earlier stages are much rarer in cases of cancer than of ulcer. Hence, in any given case, the entire absence of hæmorrhage is somewhat in

\(^1\) Constant and repeated experience has shown that such cases are not merely hypothetical.

\(^2\) The condition is evidently something more than the so-called cancerous cachexia, which is rarely, if ever, observed in cancer of external parts until suppuration has set in, or unless pain has been severe.

\(^3\) They occur in one-third of all cases of ulcer, and in only about one per cent. of cases of cancer (Brinton).
favour of ulcer; the presence of small haemorrhage alone is in favour of cancer; and the presence of large haemorrhage alone, or occurring early in the disease, is in favour of ulcer.

_Cachexia_ and failure of strength is a much earlier symptom in cancer than in ulcer. In the latter it is usually proportioned to the pain, haemorrhage, or vomiting; in the former it occurs more or less independently of these conditions. The character of the cachexia appears _per se_ to offer but few positive criteria.

_The appetite_ often presents a marked difference. It is often absent or capricious in cancer; in ulcer, on the other hand, it is frequently excessive.

_Pyrosis and acidity_, and the vomiting of glairy mucus, and conditions of indigestion, flatulency, and constipation, are common to both diseases, and offer but few distinctions, but they are somewhat more distinct in the early stages of cancer than of ulcer.

_The duration and course_ of the two disorders are, however, markedly different. That of ulcer may be almost indefinite. It is interrupted by long intermissions, and seldom presents a distinct uniform deterioration of the health and strength. The progress of cancer, on the other hand, from the period that the more distinct symptoms have declared themselves is rapid, tending to a fatal issue within nine or ten years. The intermissions, also, when they occur, are of shorter duration, and are seldom complete. Exceptional instances at times occur, but they are insufficient to invalidate the general rule observed.

_Perforation of the colon_ is, as before stated, in favour of the cancerous nature of the disease.

_Dilatation of the stomach_ and obstruction of the orifices, together with the vomiting of sarcinae, when occurring to any marked extent, are more common in cancer than in ulcer; but this, like other points of comparison, is only true as a question of degree.

5. After the appearance of a tumour, the diagnosis becomes more definite; the fallacies, however, of its position and occasional disappearance, which have been before alluded to, require to be recollected. Ulcers of the anterior surface and of the pyloric extremity are occasionally attended with a degree of thickening, which may give rise to a fallacious sensation of a tumour; but in these cases the induration is not so distinctly circumscribed, nor is the resonance on percussion so absolutely dull, as in cases of gastric cancer. The other peculiarities arising from the infiltration of the coats in the latter disease have been before described.

Other fallacies, however, exist in cases of cancerous tumours of the lymphatics, of the small omentum, of the liver, of the head of the pancreas, and of the peritoneum, and great omentum, which may at times perforate the stomach from without. When this event does not occur, the diagnosis must depend on the absence of the more prominent symptoms referable to the stomach: if the stomach is implicated, the diagnosis must become practically almost impossible
without further details in the history of the case, which lie beyond the scope of this section.

It is only necessary to allude briefly to the possible fallacy of spasm of the first division of the rectus muscle simulating a tumour. This can be distinguished by its quadrangular shape, its superficial character, and by the resonance on percussion; which, however, is sometimes masked by the tension of the muscle.

6. The diagnosis of the pain of cancer of the stomach from attacks of _colic_ is often, in its earlier stages, one of great difficulty. The distinction mainly depends upon the same data as serve to distinguish attacks of the latter affection from cases of ulcer (see p. 918).

_The Treatment_ of cancer of the stomach can, unfortunately, be only palliative. In their main features the indications are almost identical, both in diet and medicinal treatment, with those laid down for cases of ulcer; but as food has less influence on the pain, a rigid diet is not to be persisted in so strenuously, when it fails to relieve. Still, however, small meals of easily assimilable food, presented for the most part in a fluid form, prove in many cases very advantageous: a moderate use of alcoholic stimulants is, however, in most cases beneficial. For the relief of pain, opium is the most effectual remedy, and in some cases, when the growth has formed adhesions with the anterior wall, I have found hypodermic injections of morphia of great benefit. Fomentations, leeches, and even blisters to the epigastrium are also of service. Vomiting is most effectually controlled by ice, but effervescents, hydrocyanic acid, and creosote may at other times be employed with advantage. Offensive eructations associated with sloughing of the tumour are often mitigated by the use of charcoal.

Dr. Walshe states that he has found a combination of trisnitrate of bismuth with extracts of hop, conium, and stramonium in pill more useful than any other medicine. He also recommends the oil of cajeput for the relief of flatulence. Constipation may be remedied by enemata, but purgatives by the mouth should be as far as practicable avoided.

The treatment of hemorrhage must be conducted on the principles already laid down. The vomiting of sarcinæ may at times be controlled by the administration of the alkaline hypoosulphites.

_**VIII.—Hæmorrhage from the Stomach.**_

**SYNONYM.—Hæmatemesis.**

Hæmorrhage from the stomach is usually only a symptom or a result of some other disease of the mucous membrane, or of a condition of congestion induced by disorders in the portal circulation by causes extrinsic to this viscus. It will only, therefore, be necessary
to give a brief retrospect of these, many of which have been already alluded to.

It may be considered as practically proved that escape of the blood corpuscles from the capillaries cannot take place without rupture of the latter, and that the former theories respecting the so-called "haemorrhage by exhalation" are in the present day practically untenable. The foundation for this opinion has mainly rested on the fact that often after death no source for the effused blood is discoverable, but in previous sections an attempt has been made to show the causes which even after extreme congestion, during life, induced a post-mortem pallor of the mucous membrane. The rupture of the capillaries is often associated with haemorrhagic erosions, the appearances of which have been already described.¹

Haemorrhages from the stomach may, therefore, be divided into two main classes, viz.: (a) those in which it proceeds from larger vessels, and (b) those in which it is derived from capillary sources.²

Perforation of large vessels may arise from mechanical causes,³ or from the rupture of vessels through atheromatous changes; ⁴ but the most frequent, if not the exclusive, sources of haemorrhage of this kind arise in the progress of the chronic ulcer and of cancer, to which no further allusion appears necessary.

Haemorrhage from congestion may arise when this is simple and passive. It is a very common complication of obstructions of the portal circulation, especially by cirrhosis or acute atrophy of the liver, or by thrombosis of the portal vein,⁵ which are among the conditions which give rise to the largest haemorrhages from this cause, and some of which have been found attended by a varicose condition of the veins of the stomach. Diseases of the heart and lungs, and asphyxiating conditions, such as epilepsy⁶ and strangulation, are also causes of haemorrhage less extensive in amount than those before cited. It is probably to obstructions in the portal, cardiac, or pulmonary circulation that the haematemesis and melena of newly-born children are due, though in some cases the existence of a deficiency in the nutrition and elasticity of the capillaries is evidenced by the co-existence of a haemorrhagic diathesis, either hereditary or not.⁷

In other cases, also, there is probably, in addition to congestion, some alteration in the coats of the capillaries, as in diseases of the spleen, where, however, the mechanism of its origin is not fully

¹ See Chronic Catarh, p. 879.
² Another and rarer cause has been noticed in the bursting of an aneurism of the cardiac axis into the stomach, Bamberger, loc. cit. 246.
³ As in the case of a fork swallowed, Velpeau, Mem. Acad. de Méd. (Budd, 277).
⁴ Copland, Med. Diet. ii. 93.
⁵ For illustrations of all these forms, see Frerichs, Dis. Liver. An interesting case of haemorrhage, from portal thrombosis, is recorded by Dr. Andrew Clark, Path. Soc. Trans. 1867, p. 61.
⁶ Budd, loc. cit. 51; Yellowly, Med.-Chir. Trans. iv.
⁷ A very complete account of this affection is to be found in Barthez and Billiet, Malad. des Enfans, ii. 309.
explained. In the same manner are probably produced the haemorrhages of yellow fever, and of other malignant intermitents, as also those which occur in relapsing fever, typhus fever, cholera, purpura, scurvy, and hemorrhagic variola.

In other cases, though probably referable to the same source, its mode of origin is less explicable; as when it follows severe surgical operations, or blows upon the back or epigastrum. In the same class belong also hæmatemeses, occurring vicariously of the menstrual period, which, however, when independent of ulceration seem to be less frequent than was at one time supposed. In other cases, also, it may arise through the mechanism of embolism and thrombosis. (See Ulcer.)

**DIAGNOSIS.**—It must be recollected that blood vomited does not always proceed from the stomach, but may have been swallowed after having been effused from the nose, mouth and throat, cesophagus, or lungs. The characters vary with the amount and rapidity of the haemorrhage, and with the length of time which it has remained in the stomach.

1 When the haemorrhage occurs in connexion with disease of the spleen, it has usually been associated with enlargement of that organ, as the result of acute; but a case of hæmatemesis is given by Dr. Watson, Ed. Med. Journ. June 1858, where in addition to splenic enlargement there was an abnormal distribution of the splenic vein, together with an obstruction from phlebolithes in its exterior. In a large number of these cases the liver is simultaneously diseased; but that this is not always present is shown by a case by Dr. Budd, loc. cit. p. 70. The cause in some cases is probably a complex one, for other haemorrhages, as into the skin (Pierry), or from the nose, which was noticed by Hippocrates (Ἑρμής, ii. § 165, Kuhn’s Ed. iii. 450), are very common. These have also been witnessed by recent observers, as by Bamberger, loc. cit. 654; and though it is difficult to believe that any alteration in the composition of the blood, except when attended with complete breaking-down of the red corpuscles (which has not been shown to take place), can permit of its escape from the capillary walls, yet it is very probable that the nutrition of the vascular system may, in these cases, be so profoundly affected as to cause their easy rupture under slight pressure. In some cases, as believed by Siebert (Henoch, loc. cit. i. 54), the contractility of the splenic tissue may contribute to the result, as a rapid diminution of the size of the spleen has been observed after copious haemorrhage of this nature.

2 Murchison, Continued Fevers, pp. 336-7. 3 Budd, loc. cit. 68.

A case of this nature was communicated to me by my friend and colleague, Mr. Berkeley Hill, when after an operation severe hæmatemesis occurred, for which after death no cause could be discovered. Dr. Jenner informs me that he has seen similar instances. In relation to it may be recalled the observations of Rokitanski upon hæmorrhage from the bowels after severe burns (Path. Anat. iii. 200). 4 Dr. King Chambers, Indigestions, p. 190. Bamberger, loc. cit. 245. Another is quoted by Henoch, i. 307. It is possible that in some of these cases laceration of the mucous membrane, without rupture of the other coats, may be the cause of such hæmorrhage. An instance of this nature is recorded by Dr. Wilks, Path. Anat. 1857, p. 275. Laceration of the mucous membrane of the stomach from the dragging of an omental hernia is described by Rokitanski, Path. Anat. iii. 162.

5 A very remarkable case of this kind is, however, given by Sir T. Watson, Prin. Pract. Phys. ii. 425, when vicarious menstruation recurred regularly, ceased with pregnancy and lactation, and returned after weaning. He quotes also from Mr. North two other fatal cases. Dr. Murchison has cited another of older date (1712), Med. Chr. Trans. xlii. p. 46; and Henoch, loc. cit. i. 57, has observed the same phenomenon coincidently with an acute swelling of the spleen, which disappeared after the haemorrhage of the stomach and intestines.
DISEASES OF THE STOMACH.

In larger hæmorrhages, when the blood is rapidly poured into the stomach and quickly ejected, it may be coagulated, and may retain its normal colour, or may be only slightly blackened by the gastric juice.

Blood more slowly effused is acted on by the gastric juice, which prevents its coagulation, and frequently dissolves the envelopes of the red corpuscles, so that under the microscope only flakes or granules of pigment may be discoverable. In other cases the corpuscles are shrivelled and irregular in form and size. The colour of the blood is then changed to a rusty chocolate brown or coffee-ground tint, and it is sometimes of a tarry consistence. Sometimes the altered corpuscles and pigment granules sink to the bottom of the vessel, leaving a clear supernatant fluid.

The presence of the blood can, however, be generally recognised: for bile seldom loses its more characteristic tint, nor does it assume the coffee-ground appearance just described. Food stained by ferruginous medicines will sometimes present a similar appearance; but microscopic, and, if need be, chemical, examination will then suffice for its distinction.

Blood, however, effused from the stomach is not invariably vomited, but may pass into the intestines and be voided by stool (melæna).

Difficulties may, under such circumstances, arise in deciding from what portion of the canal the blood has proceeded. Independently of distinct evidence of local disease, this may not always be possible, since blood proceeding from the upper part of the intestines has usually the same characters when voided by stool as that derived from the stomach. Blood from the duodenum may also be regurgitated into the stomach, and be evacuated by vomiting.

Cruveilhier was of opinion that blood effused from the stomach retained its rusty tint throughout, while that originating from the intestines was of a more inky character; but this distinction is not always applicable. The chief means of distinction depends on the more or less intimate intermixture of the blood with the faecal matter, which diminishes in proportion as its source approaches the lower portion of the canal. The existence of disease in the latter (ulcerations from tubercle, typhoid, dysentery, cancer, or the presence of hæmorrhoids) also facilitates the diagnosis. In some cases, as in disease of the liver, we must often remain in doubt, since this cause may give rise to hæmorrhage from any part of the tract.

The characters of altered bile in the stools are to be distinguished by dilution with water. Blood under these circumstances gives a redder tint. Bile pigment can sometimes be distinguished by nitric acid; but bile seldom produces either the tarry or rusty appearance derived from altered blood.

The blackening of the feaces from ferruginous and other metallic preparations can usually be distinguished by the tint, and also by the history of the case.

The distinction between hæmorrhage from the lungs and that from

1 Bamberger, loc. cit. 252. 2 Bamberger, loc. cit. 251.
the stomach is not always easy. Difficulty may arise either when blood is vomited immediately after its effusion in the stomach, so as to escape changes from the gastric juice, or when that proceeding from the lungs has been swallowed, and subsequently vomited in an altered condition. In some cases, also, of mitral disease, blood proceeding from the lungs has been known to present a "bistre" or sooty tint. In exceptional instances there may also be a double fallacy in the expulsive act attending each condition, for haematemesis may sometimes give rise to cough, and hæmoptysis may occasionally excite vomiting. The criteria ordinarily laid down are, however, usually sufficient when a patient is under observation, though it is sometimes more difficult to draw positive conclusions from the history of past attacks.

Blood proceeding from the lungs is generally frothy, aërated, non-coagulated, florid in colour, and alkaline in reaction.

That derived from the stomach is either blackened and rusty, or it may be coagulated and altered externally. If it has been at all delayed in the viscus, and unless it is in excessive quantities, it is acid.

Hæmorrhage from the lungs is preceded or attended by a sense of weight and oppression in the thorax, together with a sense of dyspnœa and tickling cough, or with a sense of bubbling in the chest. Tinged sputa often precede and almost constantly follow the larger flow, and these are brought up by coughing, are frothy and aërated, and mixed with mucus or pus. It may be the first symptom in a certain proportion of cases, but physical examination of the lungs and heart will, almost without exception, disclose evidence of disease in these parts.

Hæmorrhage from the stomach is seldom, if ever, the first symptom of disease of this organ. It has usually been preceded by dyspeptic symptoms, or in the vast majority of instances by pain, nausea, or vomiting. The attack is proceeded by nausea, and the expulsive act is almost invariably distinctly one of vomiting; it is not followed by cough or bloody sputa. Examination of the abdomen will usually reveal gastric tenderness, or the signs of disease of the liver or spleen.

The diagnosis of the disorders of the stomach in which the hæmorrhage originates must be determined by their distinguishing features, which have been previously considered.

The Symptoms of hæmorrhage from the stomach have been already described (see Ulcer of Stomach).

Prognosis.—Severe hæmorrhages from the stomach are occasionally directly fatal; the author’s conviction is, that this is more frequently the case when they arise from cirrhosis of the liver than when originating from ulcer or cancer of the stomach. In the latter

1 Walshe, Diseases of the Lungs, 416. 2 See Walshe, Diseases of the Lungs.
DISEASES OF THE STOMACH.

949

disorders, however, they contribute largely to a finally fatal result by the exhaustion and anaemia which they induce.

The Treatment consists of rest and the administration of haemostatics.

In some cases, when the haemorrhage proceeds from congestion through obstructed venous return, particularly when the cause resides in the liver, it is benefited by purgatives;1 but these are strongly contra-indicated in cases of ulcer and cancer. With the above exceptions, cold and astringents must be resorted to. Ice, in small pieces, may be sucked constantly. Turpentine, acetate of lead, tannic acid, the perichloride of iron or alum, or the infusion of matico, may also be tried. My own experience leads me strongly to prefer the acetate of lead in the majority of cases.

When the haemorrhage is severe, the head must be kept low. Brandy may be administered by the rectum, or ether inhaled. If temporarily arrested, abstinence from food should be practised as completely as possible for some time, and nutriment should only be given in a fluid form, in very small quantities, and cold, so as to avoid both the afflux of blood during the digestive act, and also all movement of the stomach.

IX.—HYPERTROPHY OF THE WALLS OF THE STOMACH.

SYNONYMS.—Cirrhosis; Plastic Linitis (Brinton); Fibroid Induration (Handfield Jones); Sclerosis (Snellen).

Thickening of the coats of the stomach appears to be a rare disease, and one that is at present but little associated with any definite group of clinical symptoms. It is also one regarding which much confusion has existed, and on the nature of which some doubt still remains in the writings of pathologists.

Andral, who furnished the first systematic description of it,2 confounded it with scirrhous induration; or, rather, he described that form of cancer in the stomach as consisting only of a thickening of the coats of the organ, induced by chronic inflammation—an opinion which has been further supported by Bruch.3 Hypertrophy of the muscular coats is a common result of pyloric obstruction.4 Cases of general thickening to any extreme degree of the coats of the stomach, independently of such causes, though occasionally met with, are nevertheless of extreme rarity.

Thickening of the mucous membrane from chronic catarrh has been already described; but this condition does not usually invade the sub-mucous tissue, nor is the muscular coat generally affected.

In the cases, however, described under this head, a general thickening of all the coats ensues, which, however, especially affects the muscular and submucous layers. In some cases this is found more particularly in the pyloric region, under which circumstances that orifice is usually considerably narrowed. In other instances it implicates to a greater or less degree the whole of the organ.

In some cases the thickening has apparently resulted from abnormal growth of fibrous tissue, which has indurated the coats, and caused wasting of the muscular substance, but in which no evidence of a cancerous nature has been found by microscopic examination. Rokitanski considers that this change may sometimes be the final result of supplicative inflammation in the submucous tissues.

The coats of the stomach may, under these circumstances, attain a thickness of an inch or an inch and a half. The mucous membrane is thrown into folds, and in some cases has been found thinner than natural (Dr. H. Jones). The cavity of the stomach, in a case recorded by Dr. Hare, was much contracted, so as only to contain about four ounces of fluid.

The symptoms in the recorded cases have varied, and have been complicated with the presence of ascites (Dr. Wilks), and with recent peritoneal inflammation (Dr. Hare and Dr. Wilks); or, when the disease has been limited to the pylorus, with the signs of obstruction. Vomiting, which has sometimes been attended with the ejection of matter of coffee-ground appearance, has been noticed in some instances; and pain, but not of a severe kind, has usually been present. Gradual emaciation has also been observed. The cases have generally been chronic; in some instances proceeding to a fatal termination in two or three years. In some cases the stomach has formed a distinct tumour, perceptible through the parieties, but which has, however, been resonant on percussion (Louis, Dr. Hare).

The causes of this condition, independently of the observation of Rokitanski, are very obscure, and, from its extreme rarity, the disorder must be considered at present to be one which presents features rather of pathological than of clinical interest.

The main features by which it can be pathologically distinguished from scirrhus of the stomach have been already alluded to. (See note, p. 935).

1 See a case of this kind reported by Dr. Hare and examined by Dr. Lionel Beale, Path. Soc. Trans. iv. 129. Another case reported by Dr. Quain, but in more doubtful terms, is in the same volume. Another case is reported by Dr. Handfield Jones, Stomach, p. 121. A preparation of great hypertrophy of the muscular and subserous coats, with no history attached, is in the museum of University College. Four cases are also given by Dr. Hughes Bennett, Cancerous and Cancroid Growths; and another by Dr. Wilks, Path. Soc. Trans. xiii. 83. In Dr. Wilks' case a similar change was found in the intestines. Two cases of the affection limited to the pylorus are recorded by Dr. Habershon, Obs. Allin. Canal, 1857, p. 99. Several cases are also recorded by Brand, Ueber Stenosen des Pylorus, Diss. Jenaug. Erlangen, 1851. Also a case by Suellen, Canstatt. Jahrb. 1856, iii. 302, where the disease followed an injury to the epigastric region and affected the whole stomach.
DISEASES OF THE STOMACH.

X.—STRUCTURE AND OBSTRUCTION OF THE CARDIAC ORIFICE OF THE STOMACH.

SYNONYM.—Stenosis of the Cardia.

This affection is comparatively rare, except when caused by cancerous growths occluding or contracting the orifice. Simple spasm appears occasionally to cause temporary obstruction of this nature. It may, however, result from the cicatrices of simple ulcers, or of such as have been caused by swallowing corrosive poisons. Foreign bodies impacted at the cardiac orifice may, it is said, act as a cause. Obstructions may also result from aneurismal or other tumours pressing on the oesophagus at any part of its course. The symptoms of such pressure are almost identical with those of occlusion from disease of the canal.

The primary effect of these obstructions is the regurgitation of food into the mouth. The secondary consequences are those of starvation, proceeding more or less rapidly according to the degree of obstruction present.

The regurgitation into the mouth of the food delayed at the cardia takes place by an act resembling vomiting. The characters of the food thus returned depend on the degree of obstruction, or on the amount of dilatation which the oesophagus has undergone.

When the obstruction is incomplete, fluids may pass when solids are returned. A degree of spasm, or sometimes of paralysis, is often combined with the mechanical obstacle, since the facility of swallowing varies at different periods; and a narrow tube can sometimes be passed through the obstruction, by which patients may be fed, when all the food appears to be regurgitated. When dilatation of the oesophagus has not ensued, the food is very quickly returned, almost unaltered, except by mastication. When, however, the increased calibre and diminished muscular powers of the oesophagus above the seat of the obstruction admit of its retention, it becomes changed by maceration, or it may undergo fermentation or putrescent changes, which give rise to offensive eructations, and the matters ejected are often covered or mixed with a quantity of tenacious mucus.

Pain is generally felt, especially during deglutition: it is commonly referred to the ensiform cartilage or mid-dorsal region. The pain is seldom very severe, except when ulceration is present. In the intervals of deglutition there is often a dull sense of uneasiness. In many cases the patients are distinctly conscious of the point where the passage of the food is arrested.

1 Bamberger, loc. cit. The author desires to express his obligation to this writer for much of the systematised information contained in this and the ensuing section.
The passage of a bougie will almost certainly indicate the point of obstruction; but this should be cautiously practised, owing to the danger of laceration of the oesophagus. The appetite is unimpaired, and patients often suffer intensely from hunger and thirst. Emaciation proceeds pari passu with the degree of obstruction. Dropsy of the lower extremities, supervenes in some cases. Hectic is occasionally observed.

The termination is almost invariably fatal, except in cases of simple cicatricial narrowing, where dilatation may sometimes be practised. Death finally ensues by asthenia, or by pneumonia, or gangrene of the lung, or by rupture of the oesophagus.

The Pathology of these cases depends on the discovery of the cause. In most instances of cancerous obstruction of the orifice the obstruction is due to scirrhous. Higher in the oesophagus epithelial cancers are an equally frequent cause.

The stomach, in the later stages of the disease, is often greatly diminished in size, so as not to exceed that of the intestines. No special alteration of its mucous membrane has been recorded.

The Diagnosis of the obstruction is usually easy. It is determined by the character of the food regurgitated, by the obstruction felt in swallowing, and by auscultation during the act of swallowing. The passage of the bougie serves to distinguish between the effects of organic stricture and of simple spasm, and also to determine the site of the obstruction. Percussion will occasionally ascertain the existence of dilatation of the oesophagus. The diagnosis of the cause of the obstruction must in a great measure depend on the history of the case. Spasmodic obstruction is intermittent, and is almost invariably associated with the hysterical diathesis. Simple cicatricial contractions are very rare, except when corrosive fluids have been swallowed. The regurgitation of blood or pus, or in rarer cases the discrimination of cancer cells in the matters vomited, would indicate, in all probability, the malignant nature of the obstruction.

The Treatment consists in administering food in a liquid form of nutritious properties. The fact that, in some cases, a tube can be passed, will suggest this mode of giving nourishment. Nutritive enemata may also be administered. Thirst may in some persons be allayed by baths. Opium is also of value in diminishing the sufferings of the patient: it may be given in small quantities, both by the mouth, by enemata, and by the hypodermic method. Dilatation may in some cases be successful, when the stricture is clearly traceable to cicatricial contractions resulting from corrosive poisons. Dilatation by the bougie, bismuth, the valerianate of zinc, small doses of strychnine, and iron are useful in hysterical cases.

1 Dr. King Chambers: see ante, Vomiting.
The attempt to relieve the patient by gastrotomy and the establishment of a gastric fistula has not hitherto proved successful, but it would appear on many accounts deserving of a trial; though in the majority of the cases, which result from cancerous growths, the fatal termination could only be delayed by such a procedure.¹

XI.—STRUCTURE AND OBSTRUCTION OF THE PYLORUS.—DILATATION OF THE STOMACH.

Stenosis, Constriction, and Obstructions of the Pyloric Orifice are comparatively rare, independently of obstructions from cancers and other tumours of the mucous membrane, or from the cicatrices resulting from the healing of ulcers, or sometimes from the effects of corrosive poisons.²

Pyloric stenosis may, however, result from the induration of the submucous tissue described in a previous section, which may affect the stomach throughout, or may be limited to the pyloric ring. It appears also, occasionally, to result from hypertrophy of the muscular coats limited to this portion of the organ, a form of disease which, as stated by Dittrich, appears to occur with preponderating frequency in the earlier periods of life.³

Whether spasm can continue sufficiently long to produce any of the more serious symptoms resulting from organic disease must be regarded as very questionable.

Obstruction to the exit of food from the stomach may also arise from the pressure of tumours originating externally to the organ upon the pyloric orifice or first part of the duodenum. The most common of these are cancerous growths of the pancreas, of the lymphatics in the small omentum, and of tumours of the liver. Cancer of the gall bladder has also been observed to produce this effect.⁴

The Symptoms are essentially those resulting from obstruction to the passage of food, though varied by those of the other diseases in which the obstruction has its origin.

Vomiting is the most distinct and prominent of these. Its appearance is not necessarily indicative of absolute closure of the pylorus, for Bamberger has observed it to occur in cases where the orifice would still admit of the passage of the little finger.⁵ Its characters

¹ A successful case of gastrotomy, undertaken to remove from the stomach a bar of lead which had been swallowed, is recorded by Mr. Bell, Med. Times & Gaz. March 31, 1860. Another for the removal of a knife is quoted by Mr. Gray, Holmes Syst. Surg. ii. 383. In this article a tabular statement is given of the cases where this operation has been attempted.
² Dr. Markham, Path. Soc. Trans. x. 160, a case of obstruction of the pylorus as a secondary effect of swallowing Burnet's fluid.
³ Brand, loc cit. p. 15. ⁴ Dr. Markham, Path. Soc. Trans. viii. 243.
⁵ Bamberger, loc. cit. 253.
and time of appearance, however, greatly depend on subsequent changes in the stomach, and especially on the degree of dilatation which the organ undergoes—a condition which, as it may occur (though rarely) independently of pyloric obstruction, requires a separate description.

Dilatation of the Stomach is a common and almost constant result of constriction of the pyloric orifice, unless this is counterbalanced by muscular hypertrophy. It may, however, result independently of any obstruction to the pylorus, under certain circumstances, which deserve consideration. Thus:—

(a) Weakened conditions of the muscular coats, arising from malnutrition or impaired innervation, are a very common cause of not inconsiderable dilatation of the stomach. Such conditions arise in the course of severe general diseases, such as fevers, or from local causes in cases of peritoneal inflammation. They are also common in cases of hysteria, hypochondriasis, and in some diseases of the cerebrospinal centres, and also in some instances when the probability of one or other of the latter class of causes having existed is rather a matter of inference than of positive proof.¹

(b) Paralysis of the muscular coat, limited to the pyloric portion, and preventing the propulsion of food into the duodenum, has also been observed to cause secondary dilatation of the stomach.²

(c) In addition to these causes, obstruction of the duodenum, or even of the upper portion of the jejunum,³ has been followed by the same result. Excessive eating of vegetable food⁴ has been described as a cause by Dr. Hodgkin. Dislocation of the stomach and dragging of the viscus by omental hernias are mentioned as causes by Bamberger.

The symptoms of this condition are divisible into two classes: firstly, the evidence of the delay of the food for an unnatural period in the stomach; and, secondly, the physical signs resulting from the dilatation of the organ. It is only in comparatively rare cases that the dilatation, when proceeding from other causes than pyloric obstruction, is accompanied by the severer objective symptoms, and, with a few exceptions, the description of these refers almost exclusively to this class.

The immediate result of the retardation in the propulsion of the food is the production of fermentative changes; which are evidenced

¹ See an interesting case of this class by Dr. Humby and Mr. Miller, Path. Soc. Trans. iv. 137. The invasion of the disease was comparatively sudden. There was vomiting, and the patient died after eleven days' illness. She was seen by several physicians, among others by Sir T. Watson and Dr. Bright. The stomach reached to the pubes; the muscular coat had in some places given way, but no cause for the distension could be discovered. A somewhat similar case is recorded by Andral, Clin. Méd. ii. 122.

² As in a case by Andral, Clin. Méd. ii. 117, where there was extensive ulceration of the pyloric region without obstruction, and yet extreme dilatation of the stomach. The same condition of dilatation was observed in another case, where, in conjunction with induration of the coats of the pylorus, the muscular coat was atrophied, but the pyloric opening maintained its natural size. In this case also there was dilatation. Ib. p. 115.

³ Ib. p. 129.

⁴ Lect. Serous and Mucous Memb. ii. 277.
both by the tympanic distension of the organ, and by the matters vomited. The nature of the changes thus undergone by the food, and the products of these, have been already considered. (See ante, p. 792). The matters vomited are almost invariably frothy and acid, and in the scum on the surface torulae and sarcinae are commonly found.¹ (See ante, p. 793). The alterations in the food vary with the duration of its delay in the stomach; sometimes the last meal is returned, while previous ones are rejected—a difference probably due to the relatively greater fluidity of the latter. The amount vomited and the length of intervals between the act also vary in proportion to the degree of obstruction of the pylorus, or to the extent of the dilatation, or the paralysis of the muscular coats. The vomiting generally occurs at longer periods after eating than in most of the other diseases of the stomach, though sometimes the act is much delayed both in ulcer and in gastric catarrh. When, however, the dilatation or paralysis are extreme, days may elapse between the recurrences of this symptom, but under such circumstances enormous amounts of altered food may be ejected.

Bamberger remarks that the vomiting may cease if complete paralysis of the muscular coat should ensue.

Eructation and heartburn are often observed to precede the vomiting, and in some cases acidity, apparently resulting from hyper-secretion, has been noticed.²

The appetite is variable. It is sometimes considerable, or even excessive; but in some cases this is attributable to the vomiting. Emaciation is an almost constant result: the extent to which it proceeds depends on the amount of food retained and assimilated. Constipation is, as might be expected, nearly invariably present. Dropsical swellings of the lower extremities have been seen in some cases.

The physical signs are those of extreme distension of the stomach. The tympanic note of the organ may be heard over the extent which it occupies, though sometimes, when food is present in its interior, the inferior portions may be dull on percussion, and the dulness may change in site with the position of the patient. The distension may be so great as to push the diaphragm upwards. The tympanic resonance may reach even to the fourth rib, displacing the heart’s apex upwards and forwards. Sometimes the prominence formed by the distended stomach can be perceived by the hand in the epigastic, umbilical, or pubic regions, and the shape of the organ may sometimes be recognised by the smaller curvature being well defined; and in some cases, particularly when there is hypertrophy of the muscular coats, the movements of the organ can be distinctly felt, and may be excited by external stimulants. In some

¹ It would appear not improbable that in the cases recorded by Dr. Budd and Mr. Busk, when sarcinae appeared without evidence of pyloric obstruction, but in consequence of injury, that the cause of the fermentative action may have been due to a failure of the propulsive power of the stomach due to paralytic causes. ² Bamberger, loc. cit.
cases the obstructing tumour can be perceived at the pylorus, but this, for the reasons before stated, is not constant.

Auscultation sometimes gives a splashing sound on movement, which, Bamberger says, is one of the best signs of this form of dilatation. In other cases, during drinking, the fluid may be heard and felt by the patient to pass into the large cavity. The heart's sounds may be occasionally heard to consonate in the distended organ.

**THE PATHOLOGY** of this affection has been already alluded to under its ætiology. The size attained by the stomach may sometimes be very considerable; it may fill the greater part of the abdominal cavity and it may reach even to the pubes.¹ The chief point of further practical interest in these cases is the condition of the muscular coat. This may sometimes be thickened, and under such circumstances the affection is less injurious to health than when it is thinned, distended, and paralysed.

**DIAGNOSIS.**—That of obstruction of the pyloric orifice, independently of dilatation of the stomach, or of the discovery of a tumour, is surrounded by so many fallacies that certainty would appear to be almost unattainable. The only distinctive symptom is vomiting after food; and unless dilatation is so considerable as to allow of fermentation taking place, the act is seldom delayed to a period capable of enabling a distinction to be made between it and other diseases giving rise to this symptom; for in the female sex the distinction of such cases from hysterical vomiting would be excessively difficult, and it must be recollected that in either sex cancer may run its course without pain. The duration of the case may, however, assist in the diagnosis from cancer.

The discovery of a tumour or induration in the pyloric region, associated with persistent vomiting, are the only data on which reliance can be placed. The existence of a tumour would raise a presumption that the disease was of a cancerous nature; but a positive diagnosis would scarcely be justified without the presence of some of the more distinctive signs of this disorder.

When dilatation is present, the combination of symptoms and physical signs above given (and which it is unnecessary to repeat) are sufficient for its recognition. Extreme meteoristic distension of the abdomen might be confounded with cases of dilatation not associated with pyloric obstruction, when vomiting is not a prominent feature. The discrimination may then be made by the methods suggested by Bamberger, of auscultation during the swallowing of liquids, and by the passage of a sound into the cavity of the stomach, in addition to the results of percussion and the splashing sounds audible on succession of the patient.

**PROGNOSIS.**—The course and termination of cases of dilatation of the stomach depend very much upon its cause. Simple dilatations,

¹ This has been observed in cases of dilatation independent of obstruction.
DISEASES OF THE STOMACH.

without obstructions, have, however, proved fatal. When resulting from obstruction, the course of the disease is usually prolonged, though its duration is much influenced by the conditions of the obstruction. Obstructions arising from simple thickening or the cicatrization of ulcers have usually a slower progress than is observed in cases of cancer of the pylorus.

The possibility of the reopening of the pyloric ring by sloughing processes in the latter disease has been already alluded to. Bamberger has also seen a patient recover when the obstruction was, in all probability, due to the cicatrix of an ulcer.¹

TREATMENT.—The treatment of cases of obstruction of the pylorus can be only of a palliative nature.

One main indication is the administration of food in small quantities at frequently repeated intervals. It is also of extreme importance that the food given should be of such a nature that it can undergo its chief metamorphoses by the process of gastric digestion.² Hence protein substances, beef-tea, pounded meat, or, possibly, meat already digested, as suggested by Drs. Marcet and Pavy, should form the chief articles of diet. Milk should be used more sparingly. Starchy substances, which undergo acid fermentation, and oily food, should be as far as possible avoided. Nutrient enemata of beef-tea may be used with advantage. The administration of pepsine and hydrochloric acid with the food is also desirable.

Fermentation of the food associated with the vomiting of sarcina, which, if permitted to continue unchecked, greatly increases the distension of the stomach, and tends to weaken its muscular coats, may be greatly controlled by the administration of the alkaline sulphites and hyposulphites recommended by Dr. Jenner.³

Creosote is less useful in this respect, and has appeared to me to be capable of delaying, in some cases, the normal gastric digestion.

Alkalis and antacids are useful in relieving the acidity resulting from the fermentative processes. The other indications for treatment must depend on the nature and character of the obstruction. The chief of these have been already given in the chapters on ulcer and cancer.

The indications for the treatment of dilatation of the stomach occurring independently of pyloric obstruction may be summarised as consisting in the avoidance of further distension, and in restoring the tone and contractility of its muscular fibres.

Large meals should be avoided, and the food, as in the other form of dilatation, should be digestible and easily assimilable. Fermentation is also to be controlled by the means above indicated;⁴ and

¹ Loc. cit. p. 236, note.
² Kuhne has shown that when the pylorus is ligatured the whole of the food, if suited to the condition of gastric digestion, may disappear from the stomach. Lehrb. der Phys. Chemie, p. 52. ⁴ Med. Times & Gaz. Aug. 1851.
³ Dr. Budd narrates a case where a patient who had long suffered from the vomiting of sarcina obtained great relief by taking large quantities of common salt. Stomach, p. 289.
carminatives, such as cajeput, aniseed, or chamomile, may sometimes give relief.

The use of strychnia, and the taking of ice in small quantities, are the methods chiefly to be relied on for the second indication. Iron may also be used with advantage when anemia is present. Cold douches to the abdomen or spine, and galvanism to the abdomen, would appear to be deserving of a trial.

XII.—SOFTENING OF THE STOMACH.

SYNONYMS.—Post-mortem Softening of the Stomach, Self-Digestion of the Stomach; Gastromalakia; Ramollissement de l'Estomac; Magen-Erweichung. Var. Ramollissement simple; R. pultacé; R. gelatiniforme.

Softening of the coats of the stomach has already been described as one of the results of recent inflammatory action. The condition produced by this process has been spoken of as being analogous to the softenings occurring under similar circumstances in other tissues, and the appearances which it presents have been defined as consisting of swelling and increased opacity of the membrane, together with a diminution of its consistence extending for a variable depth in its substance.

Other forms of softening are, however, met with, when the membrane is of a pulpy consistence, breaking under the slightest touch; but when, instead of being opaque, it is transparent, more or less gelatinous looking, and generally, although not invariably, thinner than natural.

The nature and causes of these conditions have been much disputed; and as the opinions held respecting their true character have exercised no inconsiderable influence on the pathology and diagnosis of the disorders of the stomach, it appears desirable to devote some consideration to their real significance and to their mode of origin.

Softening, thinning, and even absence, of considerable portions of the lining membrane of the stomach, had been noticed by Morgagni,1 but the first attempt to explain these appearances was made by John Hunter,2 who attributed such changes to the self-digestion of the stomach after death, which he regarded as resulting from the action of the gastric juice on its coats, and which he believed was prevented during life by the influence of the vital principle. He confirmed his observations on the human subject by experiments on fishes, which shortly after received a further support from Spallanzani,3 who also observed that the digestion of food was continued after death. These observations were continued, and Hunter's views were confirmed by

1 De Caus. et Sed. Morbor, Epist. xxxv. 2, xliii. 22, Iv. 2.
2 Phil. Trans. 1772, republished in Obs. on Certain Parts of the Animal Economy.
3 Expériences sur la Digestion, 1783, p. 264.
Adams,\textsuperscript{1} Allan Burns,\textsuperscript{2} Wilson Philip,\textsuperscript{3} Gairdner,\textsuperscript{4} and Carswell;\textsuperscript{5} and there is a considerable uniformity in their descriptions of the appearances observed, and which they attributed to the same cause.

Stomachs in this state present, usually at the fundus, a portion where the membrane is evidently thinner than natural, or is entirely absent over an area of variable extent, while for some distance around it is softened and pulpy. The transparency of the tissue is greatly increased, allowing the white submucous coat to appear through the membrane, while the colour varies with the quantity of blood contained in the part. If this is small, the coats of the stomach are of a bluish white; if it is more considerable in amount, they are brownish or blackish. The vessels also may be seen, of a blackened colour, ramifying through the affected area, and their blackened contents may often be expressed in drops from their eroded ends.

Occasionally, but not commonly, very early stages of this process are observed, when the superficial layers of the mucous membrane are separating in flakes and are much softened, but not wholly dissolved. The surface of the membrane may have, under such circumstances, a somewhat whiter and more opaque appearance, corresponding to the form described by Cruveilhier as the Ramollissement Pultacé.

In some cases the membrane is uniformly affected; in other instances, when the stomach is contracted, the softening affects only the prominent rugæ, leaving the intervening sulci unchanged. Occasionally, also, the coats of the stomach and of the intestines are found uniformly swollen, transparent, and jelly-like, having lost all trace of structure, and resembling albumen, or presenting appearances common in tissues after the action of an acid.

The extent of surface over which the change in question may occur is variable, as is also its precise seat. The whole of the stomach has been found thus softened, but more usually the condition is limited to the fundus or posterior portions, while in other, but rarer, instances it is seen only in the pyloric region or on the anterior wall, while the parts above mentioned have escaped. Often the softened portion is found to be abruptly limited by a well-defined border; but in other cases it merges insensibly with the surrounding membrane.

The softening and erosion often proceeds to perforation of some parts of the stomach, intestines, or oesophagus,\textsuperscript{6} allowing the contents of the stomach to escape into the abdominal or pleural cavities, and in such cases analogous effects have been produced on contiguous viscera, especially on the spleen, liver, kidneys, or lungs; and in the last-named organs the change may be produced either subsequently to that of the diaphragm, or directly by perforation of the oesophagus, in the latter of which cases the alteration is usually found in the left side of the thorax.

\textsuperscript{1} On Poisons.
\textsuperscript{3} On the Vital Functions, 1817.
\textsuperscript{5} Ibid. 1830.
The edges of the perforation of the stomach ensuing in this manner are thin, ragged, eroded, transparent, and having an appearance (to use the words of Hunter) "very much like that kind of solution which fleshy parts undergo when half digested in the living stomach, or when acted on by a caustic alkali."

Other authorities have, however, maintained that the forms of softening now described may occur during life as the result of disease. The chief of these have been Jaeger, Camerer, Cruveilhier, Louis, and Andral. The three first named of these authors, and also Billard, attributed to these supposed pathological conditions a definite set of symptoms, which were said to be met with in greatest frequency among children, but were stated to occur also occasionally among adults. Their leading characteristics were enumerated as violent fever, a semi-comatose condition, interrupted by restlessness, cries, and great irritability of temper, intense thirst, pain in the abdomen, frequent incontrollable vomiting, diarrhœa, with grass-green stools, and early collapse, followed by death in a few hours, or in the course of a few days.

There has been, however, a wide diversity of opinion among these authors respecting the nature of these changes, and every shade of appearance has been described as presenting a distinct pathological character, while the significance of each of these has, in almost every instance, received a different interpretation from those who have opposed the views of Hunter and Carswell.

Thus Jaeger and Camerer attributed them to disturbances in the nutrition of the stomach, induced by impaired innervation. Andral, while recognising as inflammatory the form of softening usually attributed to that process, described the appearances now under consideration as resulting from a vital change, non-inflammatory in its nature, and analogous to the softenings which occur in the cornea under conditions of impaired nutrition. Louis, on the other hand, regarded as inflammatory the softening which Carswell had ascribed to the action of the gastric juice; but described also a form of "simple softening," which he attributed to cadaveric change. Cruveilhier again distinguished two forms; the "Ramollissement pultacé" and the

6 Maladies des Enfans, 1828.
7 An opinion still maintained by Rokitanski, Path. Anat. iii. 179. This distinguished pathologist states that precisely identical appearances may be produced in the stomach by changes ensuing before and after death. He says that the softenings of the stomach met with in cases of brain disease, and in the acute febrile and inflammatory diseases, are effected during life in consequence of disturbed innervation. It would appear, however, to the author, for the reasons hereafter to be stated, that the post-mortem nature of these changes is the more tenable hypothesis, though the softening thus found may be due to and may indicate perverted conditions of secretion existing during life.
DISEASES OF THE STOMACH.

“Ramollissement gelatiniforme;” the former being, according to him, of post-mortem origin, while the latter is caused by a vital change, “specific” in its nature, and due neither to inflammation nor to gangrene, and to which he attributed the symptoms above described as characteristic of this variety.

Recent researches have, however, tended to confirm Hunter’s opinion, and to show that the forms of softening described by Louis, Jaeger, Camerer, and Cruveilhier, and also the second form of Andral, are all to be ascribed to variations occurring in the same process of solution by the gastric juice. Cruveilhier’s arguments against this view deserve, however, to be recapitulated, since they express most of the difficulties which have beset the adoption of this explanation of all the forms now under consideration; and it is chiefly to the elucidation of these that more modern observation has been directed. He stated that the theory of Hunter and Carswell was inapplicable to cases when the oesophagus, or the anterior wall of the stomach, was affected (the body having been placed after death in a recumbent posture); that the softening is sometimes found when the stomach is empty;¹ that it can only be artificially produced by a much larger amount of acid than is found post mortem in the stomach, and that the softening of the intestines, whose contents are normally alkaline, cannot be produced by the action of an acid.

In relation to these difficulties it may, however, be stated—

(a) That, as shown by the observations of Dr. Gairdner, which have been confirmed by numerous subsequent observers, both forms of softening described by Cruveilhier have been found post mortem, unprecedented by any of the symptoms described by him and Camerer and Jaeger as characteristic of the supposed disease.

(b) The appearances thus described can be artificially produced at will in a previously healthy stomach in any part which is most dependent.²

(c) The observations of Brücke³ and Bernard⁴ have shown that for some time after death a substance continues to be formed in the gastric follicles, having all the properties of the gastric juice; and that the acid reaction, which during life is normally only found upon the surface of the mucous membrane, may within a few hours after death extend through its whole thickness. As also the gastric juice is normally formed in greater quantities in the cardiac than in the pyloric half of the stomach, the observations of Dr. Wilkinson King⁵ concerning the greater acidity of this part when the stomach has been found so softened receive a further confirmation.

¹ For a confirmation of this statement see an experiment by Dr. Blundell, quoted by Dr. Hodgkin, Morbid Anatomy of Mucous and Serous Membranes, ii. 309; where a dog which had been maintained for weeks without food, by means of the injection of blood into his veins, was nevertheless found to have softening of the stomach after death.

² Burns, Carswell, Camerer; also Williamson, Dublin Journal, vol. xix., 1841.

³ Sitzbericht der Akad. der Wiss. zu Wiem, xxxvii. 165.

⁴ Liq. de l’Organisme, ii. 377.

(d) Elsaesser's observations further show that fermentescible substances, whether milk or those belonging to the amylaceous series, undergo, not only during life, but also after death, an acid fermentation, and become capable of producing the phenomena of softening, both simple and gelatiniform, not only in the stomach, but also in the intestines; and that when these changes have occurred in the latter organs, their contents have been found to present an acid reaction.

These fermentative processes may originate in imperfect digestion, to which infants are so liable. They are, however, most easily excited through the catalytic effects of the mucus produced by catarrhal inflammation. When present, they also tend to cause the acuter forms of gastro-intestinal catarrh, the symptoms of which correspond very closely with the disorders which have been described as symptomatic of these changes in the mucous membrane, but which are really only the consequences of the inflammation thus set up. The softening, on the other hand, is, on this hypothesis, believed not to occur during life, but to be the result of the post-mortem action of the acids thus generated upon the coats of the stomach.

(c) It remains to be shown why the condition is present in some cases and not in others; and perhaps among the most important of the former class must be reckoned those cases in which the membrane has been found softened, while the stomach is empty, as has been observed by Blundell, Cruveilhier, and Dr. Budd. It is to elucidate these cases that Brücke's and Bernard's observations before quoted give the most satisfactory clue; and to these must be added the possibility brought forward both by Dr. Budd and Virchow, that in many other diseases there is a tendency to a perverted secretion of the stomach, which probably exercises a peculiarly corrosive influence after death; though, as Virchow has remarked (and his observations are supported by Camerer), the most irritating secretions formed during life appear to have no influence in producing this effect so long as vitality persists.

(f) The frequent absence of these softenings has been fully explained by Drs. Budd and Pavy to be due to the alkaline reaction of the blood, neutralizing the acidity of the gastric juice, and also to the proportion borne between the amount of this fluid in the vessels and the acid reaction of the contents of the stomach. Immunity of the posterior wall, while the anterior portion has been affected, has further been explained by the former author to depend on the gravitation of the blood to this part of the stomach; or, as in a case recorded by Burns, on the presence of an alkaline dropical fluid in the cavity of the abdomen.

(g) The process of softening appears to be only slightly influenced by external temperature—a fact explicable by the observations of

---

2 See, in support of this view, Virchow, Würzburg, Verhandl. i. 296; Archiv Path. Anat. v. 359.
3 A remarkable instance of this kind is given by Dr. Budd, On the Stomach, 1855, pp. 16, 17. Würzburg, Verhandl. loc. cit. 4 Archiv, vol. v. p. 360.
5 Croonian Lectures, Medical Gazette, 1847; and Diseases of Stomach, 1855.
6 Phil. Trans. 1853. Treatise on Digestion, 1867. Elsaesser, loc. cit. 51.
Nasse\textsuperscript{1} and Elsaesser,\textsuperscript{2} that the cooling of the internal organs of the body is not so rapid during colder seasons as might \textit{a priori} be supposed; and their temperature often remains sufficiently elevated during a period adequate for the production, by self-digestion, of the appearances described.

\textit{(b)} Lastly, when food is contained in the stomach, the effects of the fluid chyme on its coats may be influenced both by the amount and by the nature of the food. It has been long known that the gastric juice is only sufficient for the digestion of a certain amount of food,\textsuperscript{3} and, therefore, if this be in excess of the powers of the solvent, its action cannot be exerted on the containing organ; while, on the other hand, as pointed out by Dr. Brinton,\textsuperscript{4} amylaceous matters, which neutralize less of the gastric juice than albuminoid materials, tend, not only directly by their fermentation (to which allusion has already been made), but also indirectly, by exciting the secretion of an acid fluid, to give rise to this solvent action. Further, as has been stated by Dr. Budd, medicinal substances, and especially alcohol, given shortly before death, may in many cases more or less completely prevent this chemical dissolution.

From the considerations above quoted, it therefore appears that in all cases the changes in the stomach now described must be regarded as the result of post-mortem effects of a purely chemical nature; but that, in a certain number of instances, morbid conditions of the stomach, which tend either to cause an increased secretion of the gastric juice, or to set up fermentative changes in the food (especially when this consists of milk or amylaceous substances), may favour this action. It is, however, one that only really occurs to any appreciable extent after life has ceased to exist, and the appearances so produced cannot therefore be regarded as anatomical or pathological conditions to which any of the symptoms occurring during life can, with justice, be attributed.

It seems tolerably certain that these softenings are not identical with those produced by putrefactive changes in other tissues of the body, though these undoubtedly aid in increasing the degree of softness of the membrane. It is not indeed, in all circumstances, easy to discriminate the exact share attributable severally to each of these processes—which must be, to some degree, determined by the degree of cadaveric change observed in other parts. One of the most marked evidences of the latter, though not, comparatively, very frequent, is an emphysematous condition of the coats, arising from the development of gas through putrefaction in the sub-mucous tissue.

It has been already stated that the imbibition of the mucous membrane with \textit{hæmatin} may occur very early after death, and is due probably to both causes acting conjointly; but the blackened appearance of the

\textsuperscript{4} Diseases of the Stomach, p. 60.
blood in the vessels, though partly due to the action of the gases of the gastro-intestinal canal is, in great measure the result of the action of the gastric juice, as has also been explained in previous sections.

XIII.—Perforation of the Stomach

From within, formerly described as an independent disease, has received no recent trustworthy confirmation. The cases in which it has been described are now almost universally admitted to have resulted from ulcerative processes, or to have arisen from post-mortem softening. The modes of distinguishing these conditions have been already described (see Ulcer). Cases of perforation, due to foreign bodies in its interior, are, however, occasionally met with. An interesting case of perforation of the stomach, caused by an abscess of the liver, which communicated simultaneously with the pericardium, is recorded by Dr. Graves.

XIV.—Rupture of the Stomach

Has only been authentically established in cases of external injury. The symptoms have been those of collapse, followed by peritonitis. The occurrence is most likely to happen when the stomach is distended by food at the time of the injury. Whether a fatty degeneration of the muscular coat of the organ may occasion the spontaneous occurrence of this event must remain a subject for further inquiry.

XV.—Tubercle of the Stomach

Must be regarded as an exceptionally rare disease. Andral says that he only met with it twice. Willigh only found it five times in 1,317 cases. In 141 cases of tubercle in the gastro-intestinal canal, Barthez and Rilliet found the stomach affected in 21. These authors state that its seat is ordinarily in the great curvature, and that in this situation it may sometimes give rise to extensive ulcerations, which may attain the diameter of a five-franc piece.

1 See a case by Drs. Quain and Bucknill, of perforation of the stomach by a mass of cocoa fibre, swallowed by a lunatic, Path. Soc. Trans. vol. v. Another, of perforation of the duodenum in a lunatic who swallowed spoon-handles and nails, has been recorded by Mr. Poland, quoted by Mr. Pollock, Holmes' Syst. Surg. ii. 470.
3 A case of this kind occurring after a fall is recorded by Mr. Moore, Lond. Med. Rev. July 1860. A case is also given by Richerand, Physiol. i. 282, of a woman in whom, after an external injury, a fistula subsequently formed, quoted by Dr. Pollock, Holmes' Surgery, ii.
5 Prager Viertel-Jahresch. vol. i. p. 80.
6 Malad. des Enfans, iii. 183.
The author has never seen this disease commencing in the mucous membrane, but he has found a perforation of the stomach caused by tubercles commencing in the peritoneum, passing from without inwards through its coats, and thus following the tendency, observed by Barthez and Rilliet,1 of tubercles seated on the peritoneal surface of other parts of the canal.

It may possibly be questioned whether the follicular ulcerations of the stomach, so common in phthisis, may not be due to the solitary glands undergoing changes similar to those seen in other portions of the intestine, but the author has not been able to obtain any positive proof of the identity of the process in these parts.

Perforation of the stomach by a tubercular ulcer, commencing in the sub-mucous tissue of the great curvature, and attended by copious haematemesis, resulting from the invasion of the gastro-epiploic artery, has been recorded by Bignon.2 Tubercles existed around this ulceration.

In the majority of cases recorded no symptoms have been observed. In three only of the cases recorded by Barthez and Rilliet was vomiting present. The disease, in the present state of our knowledge, offers no distinctive features for either diagnosis or treatment.

Note to Dr. Anstie's article on Alcoholism

Since this article was written and printed off I have had time to make new researches, which enable me greatly to strengthen my statement as to the comparatively trifling extent to which alcohol is eliminated from the body in an unchanged form. With the assistance of my friend and colleague, Dr. Dupré, I have made experiments on a large scale, and with increased care, which prove indisputably that when alcohol is taken in non-intoxicating doses, the total elimination, in the twenty-four hours, only amounts to a fraction (generally a small one) of a grain for the kidneys, and even smaller quantities for the lungs and skin. Even in cases of intoxication I now believe that a very much smaller proportion of unchanged alcohol is excreted than even I had supposed, and enormously less than MM. Lallemand, Duroy, and Perrin, had represented. The total period during which any elimination goes on is also proved to be much shorter than had been previously supposed.

By a curious coincidence it happened that a German observer, Dr. Schulinus, was investigating the same question simultaneously with myself. His results, obtained from a very elaborate and careful series of experiments, closely correspond with my own. Dr. Schulinus' paper will be found in the Arch. d. Heilkunde for 1866. My own observations, which were made in ignorance of the German researches, are included in my lectures at the Royal College of Physicians, which appear in the Lancet of July, August, and September 1867.

F. E. A.
Note to Dr. Reynolds' article on Epilepsy.

Since the article on Epilepsy was written I have had many opportunities for observing the efficacy of bromide of potassium, when administered in larger doses than those which are usually given; and the following propositions are capable of proof with regard to its utility in the treatment of epilepsy:

1. That the cure of epilepsy is effected by doses varying, for the adult, from five grains to forty grains, given three times daily.

It often happens that the administration of five grains will diminish the frequency of attacks, or prevent their occurrence, for a period of weeks or months; but that then, the medicine being still taken, the seizures revert to their previous rate of frequency. An increase of the dose is followed by a similar succession of events; a further increase by a second succession of temporary improvement and subsequent deterioration; and so on, until a larger dose, of from thirty to forty grains, is administered three times daily, when the attacks cease altogether.

2. That it is not the mere administration of the drug, but its presence in certain quantity, that is necessary for a cure.

3. That the dose which shall prove curative is not determined by either one of the following conditions:—sex, age, duration of disease, frequency of attack, severity of attack, or form of attack; but,

4. That individual cases differ in some points, of which we know only this, that they are curable by different doses of bromide of potassium.

5. That, when not curative, it is of great value in diminishing the number of attacks; and that the dose in which it produces this effect varies between the limits I have mentioned.

6. That the number of cases in which it proves of no service, at any dose, is very small; and that the cases which resist its action do not differ in any other obvious respect from those in which the bromide is highly efficacious.

7. That bromide of potassium does no harm, even when given in the largest doses I have mentioned, for it may be taken for many months, and even for years, without producing derangement of any sort, or in any direction.

8. That the rash, or acne on the skin, which is occasionally seen, is not determined by the quantity of bromide that is taken. I have seen it after a few doses, of five grains each, have been administered;
and it has been absent in many cases where thirty grains have been taken, three times daily, for periods of six or even twelve months.

I would, therefore, earnestly recommend that bromide of potassium should not be discontinued in the treatment of a case of epilepsy, because of its apparent failure; but that the dose should be gradually increased, and the exhibition of the drug most patiently carried on for a period of many months, or even years.

J. R. R.
III.

Note to Dr. Gee's article on Tubercular Meningitis.

I. Meningeal Tubercle.

That the tubercles of tubercular meningitis are in intimate connexion with the blood-vessels is apparent to the naked eye. In Virchow's "Krankhafte Geschwülste," Bd. ii. S. 631, 638, and 639, the minute anatomy of meningeal tubercle is set forth. The adventitia, the external connective-tissue tunic of the small arteries, has in some parts of the body a lymphatic character: that is, cells which have all the attributes of lymph corpuscles, and of the proper cells of the lymphatic glands, are mingled with the stroma of the connective tissue. A "lymph-sac" of this kind invests the vessels of the pia mater. Miliary tubercles are the result of an endogenous proliferation of the lymphatic elements; a recent miliary tubercle has, as Virchow says, the closest possible resemblance to a Malpighian follicle of the spleen.

II. Tubercle of the Choroides Oculi.

In 1863 Manz (according to Virchow) described, in the Archiv für Ophthalmologie, Bd. ix. 3, S. 141, tubercle of the choroid coat of the eye. Quite recently, Mr. Soelberg Wells discovered this condition during life, by means of the ophthalmoscope: the diagnosis was confirmed post mortem (the specimen was exhibited at a meeting of the Pathological Society). Tubercle in this situation also is intimately connected with the blood-vessels.

S. J. G.
Mr. Lockhart Clarke has recently detected* definite structural changes, frequently of surprising extent, in the spinal cords of persons dying of tetanus. Here and there, promiscuously, in the white substance as well as in the grey, but more especially in the latter, were irregular streaks and masses of altered tissue, varying from a state of slight softening to one of complete fluidity, the fluid being formed of fine granules, and of the débris of the blood-vessels and nerve-tissue once occupying the parts. In the grey matter these changes were chiefly around the central canal; in the white substance they were more especially along the edges of the various fissures which transmit blood-vessels. In the walls of the blood-vessels there was no morbid deposit, nor any appreciable alteration of structure, except where they shared in the disintegration of the part to which they belonged; but the arteries were frequently dilated at short intervals, and in many places surrounded, sometimes to a depth equal to double their diameter, by granular and other exudations, beyond and amongst which the nerve-tissue, to a greater or less extent, had suffered disintegration. Mr. Clarke has found these changes in all the cases of tetanus, six in number, in which he has had an opportunity of examining the spinal cord.

These facts in the morbid anatomy of tetanus are of much interest. At the same time, it is difficult to look upon them as essential, for, if they were so, a person could scarcely recover from tetanus, except at the price of spinal paralysis, in one form or another—a result which, to say the least, is most exceptional. Moreover, these very morbid changes, instead of being characteristic of tetanus, as Mr. Clarke himself says, are “exactly similar in kind to the lesions and disintegrations which I find in various cases of ordinary paralysis, in which there is little or no spasmodic movement.”

Mr. Clarke is unwilling to regard the structural changes in question as the effects of tetanus, but, as it seems to me, without good reason. For, in my judgment, these changes only show that the spinal cord has broken up prematurely under the inordinate action to which it has been subjected—broken up, perhaps, in much the same way, if not in the very way, in which the muscles and other tissues of a hare hunted to death break up prematurely.

C. B. R.

LEEDS
SCHOOL OF
MEDICINE
INDEX.

ABDOMINAL disease, in melancholia, 15.
Abercrombie, on meningal hemorrhage, 405; on meningitis, 365; on somnambulism, 111; on tumours of brain, 478.
Abortive epilepsy, 268.
Abscess of the brain, article on, 544; including causes, 544; morbid anatomy, 547; symptoms, 549; pathology, 551; diagnosis, 554; treatment, 556; tables of cases, 557 et seq.
Abscess of brain, relation of, to insanity, 16; diagnosis from tubercular meningitis, 396.
Abluence, relation of, to alcoholism, 64, 86.
Acephalocysts, in brain, 501.
Acidity of stomach, 795.
Acute alcoholism, symptoms of, 76.
Acute gastritis, 852.
Acute indigestion, 846.
Acute mania, 22, 24.
Acute softening of the brain, 435.
Acute specific diseases, relation of, to insanity, 16.
Adams, William, on infantile paralysis, 661.
Addison, Dr. on urine of mania, 25.
Adventitious products in the brain, article on, including symptoms, 475; diagnosis, 481; morbid anatomy, 485; prognosis, 502; treatment, 503.
Affective life, chiefly perverted in one form of insanity, 17.
Affective or pathetic insanity, 32.
Age, in relation to apoplexy, 516; to atonic dyspepsia, 806; to cancer of stomach, 925; to chorea, 124; to convulsions, 221; to epilepsy, 254; to diagnosis of hypochondriasis, 299; to hysteria, 307; to locomotor ataxy, 350; to meningitis, 366; to prognosis of metallic tremor, 411; to tubercular meningitis, 372; to neuralgia, 722; to prognosis of insanity, 56; to softening of the brain, 454, 460; to ulcer of stomach, 891.
Ague, brow, 721.
Aitken, Dr. on hematoma of dura mater, 409.
Albers, on brain in insanity, 51.
Albuminuria, in convulsions, 234, 246.
Alcohol, direct effects of, 64; elimination of, 66, 525; presence of, in the tissues, 84.
Alcoholic poisoning, ultimate effects of, 66.
Alcoholism, article on, including definition, synonyms, aetiology, 63; symptoms, 71; diagnosis, 80; prognosis, 81; complications, 83; pathology, 84; treatment, 86.
Alcoholism in relation to hypochondriasis, 306.
Amaurosis, after convulsions, 227.
Amenorrhcea, in ulcer of stomach, 893.
Amyloid corpuscles, in insanity, 52, 53.
Anemia, as cause of insanity, 15; relation of, to neuralgia, 723.
Anesthesia, physiology of, 581; in hysteria, 315; before neuralgia, 718; in meningitis, 607; in meningitis, 359; in sciatica, 734.
Anesthesia, local, article on, 781.
Anesthesia muscular, article on, 330.
Anatomy, of adventitious products in brain, 485; of abscess in brain, 547; of atomic dyspepsia, 811; of epid. cere. sp. meningitis, 690; of congestion of brain, 424; of sunstroke, 162; of wasting palsy, 175; of tubercular meningitis, 391; of neuruma, 712; of softening of brain, 460; of spinal congestion, 628; of spinal irritation, 650; of spinal meningitis, 601; of myelitis, 613; of tetanus, 634; of ulcer of stomach, 895.
Aneurism, intracranial, 493; of cerebral arteries, in insanity, 52.
Angular curvature, diagnosis of, from spinal irritation, 673.
Anstie, Dr. article on alcoholism by, 63; on elimination of alcohol, 525; on hypochondriasis, 293; on neuralgia, 717.
Antimouy, in treatment of chorea, 136; of delirium tremens, 92; of insanity, 61.
Aphasia, in softening of brain, 441.
Aphemia, in softening of brain, 441.
Aphousia hysterica, diagnosis of, 323; treatment of, 328.
Apoplexy capillaire, 449.
Apoplexy, article on, including seat of effusion, 504; internal hemorrhage, 505; external, 509; size of effusion, 510; warnings of effusion, 511; age in apoplexy, and mental state, 516; rapid death from, 519; resemblance of, to alcoholism, 524; relation to injury, 526; serous apoplexy, 529; hemiplegia
INDEX.

with cornea, after convulsion, 531; without convulsion, 533; hemiplegia alone, 534; prognosis, 536; treatment, 541.

Apoplexy, congestive, 415; diagnosis of, 420, 471; in epilepsy, 274; in softening of brain, 436.

Arachnoid haemorrhage, 406, 509; resemblance of, to tubercular meningitis, 390.

Arachnoid, opacity of, in insanity, 49.

Arran, on wasting palsy, 196 et seq.

Arteries, degeneration of, in general paralysis, 50; condition of, in apoplexy, 511.

Articulare, condition of, in softening of the brain, 437, 440.

Asthma, spasmodic, 766.

Ataxy, locomotor, article on, 336; diagnosis of, from myelitis, 615.

Ataxic symptoms, including etiology, 806; symptoms, 807; pathology, 810; morbid anatomy, 811; diagnosis and prognosis, 813; treatment, 814.

Atrophy, of brain, in idiocy, 33; in insanity, 50; in softening of brain, 458.

Atrophy, local, distinction of, from wasting palsy, 173.

Atrophy, muscular, progressive, 166.

Atrophy of spinal cord, 669.

Attack, apoplectic, in softening of brain, 436.

Attack, epileptic, description of, 260; forms of, 272; frequency of, 273.

Attention, concentration of, in hypochondriasis, 296.

Auditory nerve, relation of, to vertigo, 150.

Automatic movements, modifications of, 291.

Aurum, epileptic, 268.

Bailhache, on meningeal hemorrhage, 406.

Bandaging, in hydrocephalus, 408.

Barclay, Dr. on sunstroke, 155.

Barensprung, on herpes in neuralgia, 730.

Barlow, Dr. on treatment of chorea, 131, 132.

Barnard, Mr. on hydrocephalus, 403.

Barre, on chronic gastritis, 870.

Barthet and Rilliet, on chronic hydrocephalus, 398, 401.

Bassier, on sunstroke, 151, 160.

Bastian, Dr. H. Charlton, on adventitious products in the brain, 478; on cerebritis, 430; on congestion of the brain, 413; on softening of the brain, 434; on specific gravity of brain, 51.

Baths, in the treatment of chorea, 140; of insanity, 59; of paralysis agitans, 292.

Bauet, M. on alcoholism, 76.

Bayle, on general paralysis, 36.

Bazire, Dr. V. on locomotor ataxy, 345.

Bed-sores in myelitis, 612.

Begbie, Dr. on treatment of chorea, 132.

Begbie, Dr. Warburton, on local anesthesia, 781; on local paralysis from nerve disease, 754; on local spasms, 765; on neuritis and neuroma, 706.

Bell's palsy, 757.

Bennet, Dr. Hughes, on neuroma, 710, 712; on softening of brain, 466.

Bland, Dr. on meningitis, 367.

Blister, circular, in hysteria, 320.

Bones, condition of, in chronic hydrophalus, 399.

Bouchard, on softening of brain, 465.

Boudin, on sunstroke, 157, 160.

Bouillaud, on language, 441.

Boulimia, 827.

Bourguignon, Dr. on treatment of chorea, 137.

Bowel, condition of, in locomotor ataxy, 344; in mania, 25.

Boyd, Dr. on prognosis of insanity, 56.

Brain, specific gravity of, in insanity, 51.

Breathing, in spinal meningitis, 600.

Breath, odour of, in alcoholism, 73.

Brierre de Boismont, on hallucinations, 25.

Bright, Dr. on treatment of chorea, 132.

Brinton, Dr. on cauter of stomach, 925 et seq.; on ulcer of stomach, 580 et seq.

Briquet, M. on hysteria, 310; on hysterical paraplegia, 566.

Broadbent, Dr. on anæsthesia, 505.

Broca, on aphemia, 441.

Bronchial spasm, 768.

Bromide of potassium, in treatment of chronic alcoholism, 87; of delirium tremens, 92; of insanity, 61; of epilepsy, 280; value of in large doses, 270; of tumour of brain, 503.

Brow age, 721.

Brown, J. Baker, on causes of epilepsy, 258.

Brown-Séquard, on choreic movements, 130; on myelitis, 609; on treatment of myelitis, 616; on reflex paraplegia, 655; on rigor mortis in tetaus, 685; on vertigo, 150.

Bucknill, Dr. on coma of epileptic lunatics, 268; on diagnosis of insanity, 40; specific gravity of brain, 51.

Burrows, Dr. on congestion of brain, 422.

Cachexia, in cancer of stomach, 932; in ulcer of stomach, 912.

Calmeil, on general paralysis, 36.

Cancer in brain, anatomy of, 489; diagnosis of, 485.

Cancer in spinal column, 670.

Cancer: of stomach, including definition, history, 924; etiology, 925; symptoms, 927; duration, 933; prognosis, pathology, 934; diagnosis, 941; treatment, 944; diagnosis of, from chronic gastritis, 884.
INDEX.

Capillaries, obstruction of, in brain, 456; state of, in brain, in general paralysis, 52.
Cardialgia, 786.
Caries of the vertebral column, 672.
Carswell, Sir Robert, on meningeal hemorrhage, 406.
Carter, Mr. R. B. on hysteria, 319.
Catalepsy, article on, including name, definition, description, 99; causes, 101; treatment, 108; difference of, from ecstasy, 95; relations of, to somnambulism, melancholia, quartan fever, 104; voluntarily induced, 104.
Catarrh, acute gastric, see Gastritis.
Catharr of the stomach, chronic, 867; including synonyms, definition, etiology, ib.; symptoms, 870; pathology, 879; diagnosis, 883, 917; treatment, 884.
Causes of disease, see Etiology.
Causes of alcoholism, 63; of catalepsy, 101; of 'cerebritis, 430; of chorea, 125; of congestion of brain, 419; of dilatation of stomach, 954; of insanity, 11, 17; of dyspepsia, 804; of epilepsy, 253; of hypochondriasis, 301; of hysteria, 307; of locomotor ataxy, 350; of metallic tremor, 265; of morbid sleep, 169; of muscular anesthesia, 332; of myelitis, 614; of neurosis of stomach, 823; of paralysis agitans, 185; of predisposition to alcoholism, 67; of softening of the brain, 434; of somnambulism, 109; of spinal congestion, 623; of spinal irritation, 650; of spinal meningitis, 601; of tetanus, 635; of torticollis, 774; of vertigo, 145.
Cerebellum, relation of, to locomotor ataxy, 351.
Cerebral rheumatism, 360.
Cerebral surprise, 531.
Cerebritis, article on, including causes, symptoms, 430; diagnosis, pathology, 431; prognosis, treatment, 433; diagnosis of, from meningitis, 366.
Cerebro-spinal fever, or arachnitis, 676.
Cerium, oxalate of, 839.
Cervico-brachial neuralgia, 727.
Cervico-occipital neuralgia, 726.
Chapman, Dr. John, on ice in the treatment of epilepsy, 283.
Chambers, Dr. Thomas King, article on ecstasy by, 94; article on catalepsy by, 99; article on somnambulism and allied states by, 109.
Chlorosis, in chorea, 123.
Chloroform, in cerebral irritation, 164; in chorea, 138; in delirium tremens, 91; in convulsions, 239; in epilepsy, 280.
Chorea, article on, 114; including history, varieties, 119; mental condition, muscular state, 122; sensorial changes, general conditions, 123; causes, 124; tendencies, diagnosis, 125; pathology, 126; relation to fever, 127; treatment, 131; diagnosis of, from locomotor ataxy, 352; relation of, to dance of St. Vitus, 97.
Chorea senilis, 184.
Choroid plexus, cysts in, 411.
Chronic diseases, as causes of insanity, 15.
Chronic mania, 23.
Chronic meningitis, 369.
Chronic softening, after apoplexy, 438.
Chronic softening of brain, 447; diagnosis of, from epilepsy, 278.
Churchill, Dr. on phosphites, 142.
Cicatrization of ulcer of stomach, 898.

Classification of convulsions, 230; of diseases of nervous system, 3; of insanity, commonly employed in Germany, 10; of neuralgias, 719.
Clavus hysterica, 725.
Climate, in relation to hysteria, 309; to insanity, 11.
Clitoridectomy in epilepsy, 283.
Clouston, Dr. on causes of insanity, 15.
Cod liver oil, in chorea, 141; in chronic alcoholism, 88.
Cold, application of, in epid. cer. sp. meningitis, 702; in insanity, 58; in meningitis, 368; in myelitis, 610.
Cold, in production of neuralgia, 727; of wasting palsy, 168.
Colic, diagnosis of, from cancer of stomach, 944.
Collapse, from morphia, in insanity, 61; of meningitis, 159.
Colloid cancer, of stomach, 937.
Colloid corpuscles, in insanity, 52.
Columns of spinal cord, physiology of, 581.
Coma, in apoplexy, 516; in epid. cer. sp. meningitis, 684; in meningitis, 359.
Complications of alcoholism, 89; of epid. cer. sp. meningitis, 687; of epilepsy, 274; of neuralgia, 735.
Compression, of spinal cord, 672.
Concretions, in brain, 497.
Concussion, of spinal cord, 671.
Congestive apoplexy, 530.
Congestive delirium, diagnosis of, 421.
Congestion of the brain, article on, 413; including symptoms, 414; forms, 415; causes, 419; diagnosis, 420; pathology, 422; morbid anatomy, 424; prognosis, 428; treatment, ib.
Congestion of spinal cord; symptoms, 619; anatomy, causes, diagnosis, 623; prognosis, treatment, 624.
Conquest, Dr. on hydrocephalus, 403.
Consciousness, double, 111.
INDEX.

Consciousness, loss of, in epilepsy, 265; in tubercular meningitis, 380.
Consequences of epilepsy, 274.
Contractions, in meningeal haemorrhage, 407.
Convulsionnaires, 118; de St. Médard, 95.
Convulsions, article on, 217; including convulsions in children, 219; the paroxysms, 222; clinical history, 229; premonitory symptoms, 231; prognosis, 236; treatment, 237; convulsions after seven years of age, 241.
Convulsions, congestive, diagnosis of, 421.
Convulsions, diagnosis of, from epilepsy, 277; in apoplexy, 522; in cerebral congestion, 416; in meningitis, 359; in softening of brain, 445; diagnosis of, 474; in tubercular meningitis, 374, 379; in tumour of brain, 480; relation of, to rigor, 180; general significance of, 592.
Convulsive movements, in sciatica, 735.
Convulsive tremors, metallic, 207.
Co-ordination of movements, conditions of, 290; want of, in alcoholism, 72; in locomotor ataxy, 341; in writers' cramp, 239.
Cord, feeling of, in myelitis, 608.
Corpora amylnacea, 410.
Corpus striatum, apoplexy in, 504; condition of, in chorea, 127.
Corrosive ulcer, of stomach, 889.
Cortex of brain, softened in insanity, 49.
Cough, hysterical, in chorea, 122; in spinal irritation, 645.
Countenance, in chorea, 122.
Coup de soleil, see Sunstroke.
Cramp, in epileptics, 271; in the extremities, 772.
Cramp, writers', 255.
Crazy people, in asylums, 29.
Cretinism, condition of the skull in, 34.
Crural neuralgia, 732.
Cruevillion's atrophy, 166.
Cry, epileptic, 265.
Curling, Mr. T. B. on tetanus, 629, 634, 637.
Cutaneous anaesthesia, 782.
Cysticeri, in brain, 497.
Cysts, in brain, 496.

DANCING MANIA, 96; of Abyssinia, 118.
Dance, on St. John's day, 96.
Darwin, Dr. on treatment of chorea, 139.
Davaine, on cysticeri in brain, 498.
Dax, on aphasis, 442.
Deafness, in vertigo, 144.
Death, apparent, in catalpsey, 103.
Death, causes of, in dementia, 30; in mania, 26; in melancholia, 22; in convulsions, 238; in delirium tremens, 79; in apoplexy, 519.
Debility, at onset of neuralgia, 717.
Deformities, in infantile paralysis, 604; in shaking palsy, 159.

Degeneration of brain, stages of, in insanity, 52 et seq.
De Haen, on catalepsy, 104; on metallic tremor, 285.
Delirium, in congestion of brain, 441; in electric chorea, 115; in epid. cereb. meningitis, 358; in meningitis, 358; in softening of brain, 446, 474.
Delirium tremens, 68; diagnosis of, from insanity, 39; from meningitis, 366; symptoms of, 76; treatment of, 88.
Delusional insanity, 27.
Delusions, character of, in mania, 24; in monomania, 27; definition of, 20; detection of, 41; relation of, to homicide, 21; to melancholia, 18.
Dementia, 10; diagnosis of, from melancholia with stupor, 42; extreme degree of, 30; prognosis in, 54; specific gravity of brain in, 51; resembled by melancholia attonita, 20.
De Morgan, Mr. Campbell, on division of nerves, 148.
Dentition, in epilepsy, 256.
Dewar, Dr. on somnambulism, 111.
Diagnosis, of abscess of brain, 554; of adventitious products of brain, 481; of alcoholism, 80; of apoplexy, 532; of atomic dyspepsia, 813; of cancer of stomach, 941; of cerebritis, 431; of chorea, 125; of chronic gastritis, 883; of chronic hydrocephalus, 402; of congestion of brain, 420; of epilepsy, 276; of epid. cereb. meningitis, 659; of gastric ulcers, 789; of gastric ulcer, 917; of gastritis, 860; of hematemesis, generally, 946; of hemiplegia; 535; of hypochondriasis, 298; of hysteria, 323; of insanity, 39; of locomotor ataxia, 349, 350; of metallic tremor, 211; of meningitis, 366; of muscular anaesthesia, 332; of myelitis, 615; of neuralgia, 739; of neuroses of stomach, 855; of obstruction of stomach, 952; of paralysis agitans, 196; of pyloric obstruction, 956; of reflex paraplegia, 655; of softening of brain, 471; of spinal congestion, 623; of spinal irritation, 650; of spinal meningitis, 602; of sunstroke, 161; of traumatic and non-traumatic cerebral apoplexy, 527; of tetanus, 536; of torticolis, 777; of tumour of brain, 481; of tubercular meningitis, 358; of wasting palsy, 178; of writers' cramp, 285; of diathetic convulsion, 277.
Dickinson, Dr. on coagula in vessels of brain, 534.
Dicrotism of pulse, in delirium tremens, 77.
Diet, in atomic dyspepsia, 814; in chronic alcoholism, 86; in epilepsy, 282; in insanity, 59.
Digestion, in ulcer of stomach, 911.
INDEX.

Digestive derangements, 798.
Digestive system, diseases of, 785.
Digitalis, in delirium tremens, 90; in insanity, 60.
Dilatation of stomach, 953 et seq.
Diseased grain, relation of, to epid. cer. sp. meningitis, 698.
Division of nerves, in neuralgia, 719.
Dorsal-intercostal neuralgia, 729.
Dorsal-lumbar neuralgia, 731.
Double consciousness, 111.
Double facial paralysis, 762.
Douce bath, in insanity, 59.
Douce, value of, in suostroke, 164.
Dress, in relation to sunstroke, 153.
Drunkard, countenance of, 73.
Drunkenness, resemblance of, to apoplexy, 517.
Drinking, tendency to, in hysteria, 317.
Dubini, on electric chorea, 115.
Duchâtelet, on meningitis, 412.
Duchenne, on locomotor ataxy, 336; on general spinal paralysis, 654; on the treatment of wasting palsy, 182.
Duodenum, ulcer of, 913.
Dura mater, inflammation of, 303.
Durand Fardel, on congestion of brain, 418, 426; on softening of brain, 468.
Du Parque, on softening of brain in children, 447.
Dyspepsia, varieties of, 798; a cause of vertigo, 147; acute, diagnosis of, from tubercular meningitis, 387; in alcoholism, 74; chronic inflammatory, 867; in hypochondriasis, 296; of phthisis, treatment of, 887; scrofulous, treatment of, 888; simulating tumour of brain, 478.
Dyspepsia apyrétique ou asthénique, 806.
Dyspnée, in dyspepsia, 801; in hysteria, 814; in tetanus, 830; in myelitis, 811; in spinal congestion, 622.
Dystaxia agitans, 184.
Ear, affections of, productive of vertigo, 150; disease of, cause of meningitis, 363; in abscess of brain, 545.
Eccentric convulsions, diagnosis of, from congestive, 421.
Eccentricity, diagnosis of, from insanity, 43.
Eclampsia, 220.
Ecstasy, article on, 94; causes of, 97.
Effusion, seat of, in apoplexy, 504.
Electrical properties of nerves, relation of, to insanity, 44.
Electricity, in chorea, 141; in myelitis, 618; in muscular anesthesia, 335; in paralysis agitans, 202; in treatment of hysteria, 329; of neuralgia, 751; of writers' cramp, 292; of wasting palsy, 182.
Electric chorea, 115.
Electric condition, in torticollis, 776; in general paralysis, 37; in hysterical paralysis, 317, 656; in spinal congestion, 622; in locomotor ataxy, 345; in myelitis, 611; in softening of the brain, 444; in wasting palsy, 172; in muscular anesthesia, 331; in infantile paralysis, 665.
Elimination of alcohol, 66.
Elliotson, Dr. on the treatment of chorea, 131.
Emaciation, in chronic gastritis, 874.
Embolism, in softening of the brain, 453; mental derangement a first symptom of, 17.
Emotion, effects of, in shaking palsy, 188; in hysteria, 312; in somnambulism, 110.
Encephalocele, diagnosis of, from hydrocephalus, 402.
Entozoa, a cause of local spasm, 766; in brain, 497.
Ependyma, changes of, in insanity, 50; in tubercular meningitis, 383.
Epidemic cerebro-spinal meningitis, article on, including definition, synonyms, 676; description, 677; general symptoms, 68; special symptoms, 689; complications, 687; dilatation, termination, 688; diagnosis, 689; prognosis, morbid anatomy, 690; history and geographical distribution, 691; etiology, 695; nature, 699; treatment, 701; bibliography, 703.
Epidemic influences, in causing gastritis, 844.
Epileptic attacks, in abscess of brain, 550; in alcoholism, 76.
Epileptiform attacks, in chorea, 115.
Epileptiform convolution, prognostic value of, in insanity, 54.
Epilepsy, article on, including definition, 251; synonyms, natural history, 252; causes, 253; symptoms, 259; paroxysmal, 260; interparoxysmal, 268; relations between the symptoms, 272; complications, 274; pathology, 275; diagnosis, 276; prognosis, 279; treatment, 280.
Epilepsy, a cause of insanity, 30; diagnosis of, from hysteria, 323; from tumours of brain, 481; followed by mania, 15; relation of, to fever, 180; to catalepsy, 103; to chorea, 125; to convulsions, 292; sp. gr. of brain in, 51.
Epistaxis, in apoplexy, 514.
Equilibrium, disturbance of, in shaking palsy, 182.
Erectile tumour, 493.
Eretismus of stomach, 823.
Erosion of stomach, 559.
Eructation, in stomach disease, 794.
INDEX.

Erysipelas, complicating neuralgia, 737.
Esquirol, classification of idiots by, 35; classification of insanity by, 10; on causes of insanity, 14; on characters of insanity, 27; on transmission of epilepsy, 253.
Essential paralysis of children, 661.
Essential vertigo, 149.
Etiology, see Causes.
Etiology, of cancer of stomach, 925; of chronic gastritis, 867; of gastritis, 842; of epid. ser. meningitis, 695; of meningitis, 366; of neuralgia, 742; of wasting palsy, 166; of writers' cramp, 288; of sunstroke, 157; of tubercular meningitis, 371; of ulcer of the stomach, 891.
Ether, in chorea, 138.
Ethnology, of metallic tremor, 212.
Excision, of neurona, 715.
Exhaustion, diagnosis of, from tubercular meningitis, 387; in relation to stomach nerves, 824; in relation to sunstroke, 156.
Eyeballs, synergetic condition of, in softening of brain, 439.
FACE, paralysis of, in apoplexy, 513; in tubercular meningitis, 377; in wasting palsy, 170.
Facial anæsthesia, 783.
Facial neuralgia, 723.
Facial palsy, 757.
Falret, on hypochondriasis, 295.
Faradization, see Electricity.
Fatigue, in neuralgia, 718.
Fatty degeneration, in stomach glands, 851; in vessels of brain, in insanity, 53.
Felvine form, of congestion of brain, 418.
Febris nigra, relation of, to epid. ser. meningitis, 700.
Feelings, special perversion of, in insanity, 17.
Feigned hemiplegia, 536.
Feigned insanity, diagnosis of, 40.
Fever, absence of, in chorea, 124; in cancer of stomach, 933; in chronic gastritis, 874; relation of, to chorea, 128; in spinal meningitis, 609; in tubercular meningitis, 373.
Fibrous tumour, of brain, 491.
Fibro-plastic tumour, in brain, 491.
Fifth nerve, anæsthesia of, 783; neuralgia of, 723; paralysis of, by alcohol, 65; paralysis of, generally, 764.
Folie circulare, 26.
Food (see Diet), effect of, on ulcer of stomach, 909; in delirium tremens, 89; in relation to dyspepsia, 802 et seq.
Fox, Dr. Wilson, on diseases of stomach, 726.
Fracture of skull, relation of, to abscess of brain, 544.
Fright, a cause of chorea, 125; of catastrophe, 101.
Fright of mother, a cause of idiocy in child, 34.
Flatus, 796.
Furor transitarius, 26.
Fury, manic, 22, 24.
Gairdner, Dr. on double facial palsy, 762; on meningeal hemorrhage, 405.
Gait, in shaking palsy, 189.
Galen, on hypochondriasis, 293.
Gall, Dr. on seat of faculty of language, 441.
Gall-stones, diagnosis of, from gastric ulcer, 918.
Gangrene of lung, in melancholia, 22.
Garrod, on causes of insanity, 15.
Gastralgia, 786.
Gastritis, including synonyms, varieties, definition, 841; etiology, 842; symptoms, 849; pathology, 854; diagnosis, 866; treatment, 861.
Gastritis, chronic, 867; from alcoholism, 853; from gout, 854; in young children, 851; resembling fabricula, 850.
Gastrodynia, 786; diagnosis of, from cancer, 941; from ulcer, 917.
Gastro-intestinal catarrh, diagnosis of, from tubercular meningitis, 388.
Gastrorhoea, in chronic gastritis, 877.
Gee, Dr. S. J. on tubercular meningitis, 371.
General health, of epileptics, 271.
General nervous diseases, and those of uncertain seat, list of, 7.
General paralysis, 10; anatomy of, 50; diagnosis of, from alcoholism, 81; diagnosis of, generally, 43; from wasting palsy, 173; prognosis in, 54; specific gravity of brain in, 51.
General spinal paralysis, 653.
Georget, on hypochondriasis, 295.
Gerhardt, on a case of insanity, 17.
Gilbert, on malformation of membranes, 411.
Gillette, M. on treatment of chorea, 136.
Glands, gastric, in acute catarrh, 857; tubercular, in chronic gastritis, 881.
Gliomata, 490.
Globus hystericus, 314.
Goebel on catalepsy, 104.
Goitre, relation of, to idiocy, 36.
Göils, on chronic hydrocephalus, 398.
Gower, Dr. on hydrocephalus, 403.
Graves, Dr. on local paralysis, 754.
Griesinger, classification of idiots by, 35; on lucid intervals, 22.
Grinaeus, in chorea, 122.
Guietain, on causes of insanity, 14; on stages of insanity, 23.
Gull, Dr. on abscess of brain, 544; on hypochondriasis, 293; on intracranial aneurism, 495; on reflex paraphlegia, 659; on wasting palsy, 176.
INDEX.

HALL, Dr. Marshall, on irritability in spinal paralysis, 611; on shaking palsy, 192; on trachelsms, 261.

Hallucination, definition of, 20; in delirium tremens, 77; in general paralysis, 33; in mania, 25; in melancholia, 19; in monomania, 27.

Hare, Dr. on mode of treating hysteric paroxysm, 328.

Harley, Dr. George, on strychnia, 617; on the blood in tetanus, 129.

Haematemesis, see Haemorrhage.

Haematemesis, in chronic gastritis, 878.

Haematoma, of dura mater, 409.

Haematomyelie, 666.

Hematorchis, 666.

Haemorrhage, cerebral, see Apoplexy.

Haemorrhage, cerebral, relation of, to congestion, 423.

Haemorrhage, in alcoholism, 75; in convulsions, 242; in cancer of stomach, 931; from the stomach, generally considered, 944; from ulcer of stomach, 902, 910; spinal, 666; suppression of, a cause of vertigo, 145.

Haemorrhagic apoplexy, diagnosis of, from softening, 472.

Haemorrhoids, in alcoholism, 75.

Haut mal, le, description of, 262.

Haygarth, on ecstacy, 98.

Headache, in chronic softening of brain, 448; in epid. cer. sp. meningitis, 678; in gastritis, 847; in meningitis, 357; in tubercular meningitis, 379; in tumour of brain, 479.

Head symptoms, in myelitis, 612; in tetanus, 631.

Hearing, in locomotor ataxy, 343.

Heart, disease of, in chorea, 123; in insanity, 15; in apoplexy, 538; in vertigo, 145.

Heat apoplexy, see Sunstroke.

Heat application of, to spine, in myelitis, 610.

Hecker, on dance of St. John, 116.

Heinroth, on diagnosis of insanity, 41.

Hemiplegia, after convulsions, 225, 531.

Hemiplegia, diagnosis of, from muscular anesthesia, 332; in apoplexy, 505; in hysteria, 316; with insensibility, 533; without convulsion, 534.

Hemispheres, apoplexy in, 508.

Hereditary taint, in insanity, 13; in alcoh- holism, 70; in diagnosis of hypochondriasis, 298; in epilepsy, 253; in hysteria, 310; in prognosis of insanity, 55; in moral insanity, 31; in omona- niac, 50; in tubercular meningitis, 376.

Hereditary transmission, of convulsions, 233; of somnambulism, 110.

Hepatitis, on chorea, 729, 730, 739.

Hewett, Mr. Prescott, on abscess of brain, 544.

Hiccoup, 770.

His, on congestion of brain, 422.

Histrionic spasm, 771.

Histrionic paralysis, 757.

Hoffman, on ecstasy, 94.

Homicidal impulse, in melancholia, 21; in dementia, 29.

Hope, on hypochondriasis, 297.

Hovell, Mr. De Berdt, on hysteria, 321.

Howe, Dr. on causes of idiocy, 34.

Hughes, Dr. on brain in chorea, 127; on chorea, 123; on treatment of chorea, 132.

Hydatids, an indirect cause of insanity, 16; in brain, 498.

Hydrocephalus, acute, diagnosis of, 391.

Hydrocephalus, chronic, article on, 397; including ventricular, 398; intra-arachnoid, 399; symptoms, ib.; diagnosis and treatment, 402.

Hydrocyanic acid, in insanity, 60.

Hydrophobia, diagnosis of, from tetanus, 636; relation of spasm of, to circulation, 130.

Hydrophoria, 674.

Hygienic conditions affecting sunstroke, 156.

Hypodermic injection, of arsenic in chorea, 133; of morphia in delirium tremens, 91; of morphia in insanity, 60; in treatment of neuralgia, 747; in wasting palsy, 183; in writers' cramp, 292.

Hyperesthesia, in hysteria, 313; in meningitis, 358.

Hypercinesis, 765.

Hypertrophy of brain, diagnosis of, 484; of spinal cord, 669; of walls of stomach, 949.

Hypochondriacal melancholia, 19.

Hypochondriasis, article on, 293; including definition, nomenclature, 293; history, 295; symptoms, 296; diagnosis, 298; prognosis, 301; etiology, ib.; treatment, 303.

Hypochondriasis, diagnosis of, from melancholia, 42; in chronic gastritis, 876; diagnosis of, from chronic gastritis, 883; relation of, to stomach diseases, 825.

Hystera, article on, 306; causes, 307; symptoms, 311; interparoxysmal, ib.; paroxysmal, 318; pathology, 320; diagnosis, 323; prognosis, 324; treatment, 325.

Hystera, diagnosis of, from epilepsy, 277; from hypochondriasis, 299; from tumour of brain, 492; from neuralgia, 740; relation of, to muscular anesthesia, 333.

Hysterical condition, 306.

Hysterical insanity, prognosis of, 55.

Hysterical palsy, 194, 536.

Hysterical paraplegia, 656.

Hysterical vomiting, 830.
INDEX.

1. Ac, in treatment of epilepsy, 283.
2. Ideation, in hysteria, 312; perversion of, in insanity, 17.
3. Ideational insanity, 32.
4. Idiocy, 10; description of, 33; causes of, 34; in epilepsy, 275.
5. Idiots, classification of, by speech, 35; by motility, 35.
6. Idiopathic neuritis, 714.
7. Illusions, definition of, 20; in melancholia, 19.
8. Imbecility, 35.
9. Imbert, on catalepsy, 106.
10. Impulse, destructive, in melancholia, 21; morbid, relation of, to insanity, 21.
11. Incontinence of urine, in somnambulism, 111, 112.
12. Indian hemp, in chronic alcoholism, 88; in neurosis, 750.
15. Infantile paralysis, 661; distinction of, from wasting palsy, 173, 685.
17. Inflammation, relation of, to chorea, 128; to pain, 589.
18. Injuries of the head, a cause of insanity, 16.
19. Injury, a cause of wasting palsy, 168; productive of neuralgia, 719; to spinal cord, effects of, 586.
20. Insanity, article on, 8; general plan of article, synonyms, definition, 8; classification, 10; causes, 11; forms and symptoms, 17; summary of forms, 32; diagnosis, 59; pathology, 44; morbid anatomy, 49; prognosis, 54; therapeutics, 57; causes of death in, 56; chronic, morbid anatomy of, 56; recurrence of, 56; relation of, to alcoholism, 70.
22. Insomnia (see Sunstroke), a cause of insanity, 16.
23. Insomnia, of alcoholism, 72; of delirium tremens, 77.
24. Intellect, derangement of, in insanity, 17; in meningitis, 358; in tumour of brain, 479.
25. Intemperance, a cause of idiocy, 34; a cause of insanity, 15; relation of, to general paralysis, 36.
27. Intermarriages, relation of, to idiocy, 34.
28. Intermittence of neuralgia, 718.
29. Intoxication, alcoholic, 63.
30. Iritis, in connexion with neuralgia, 738.
31. Irrigation, in meningitis, 385.
32. Irritability, relation of, to fever, 130.
33. Irritation, eccentric, in epilepsy, 250.

Jackson, Dr. Hughlings, on aphasia, 442; article on apoplexy by, 504; on brain, in chorea, 127; on retina, in locomotor ataxy, 343; article on convulsions by, 217.

Jaundice, in hypochondriasis, 298.
Jebb, Dr. On case of catalepsy, recorded by, 99.
Jenner, Dr. On convulsions, in rickets, 223.
Jones, Mr. On digitalis, in delirium tremens, 90.
Junod's boot, in treatment of myelitis, 618.
Jussieu, on mercurial disease, 210.
Kelly, Dr. On congestion of brain, 422.
Kidney, in alcoholism, 85; in apoplexy, 511.
Kirkes, on thrombosis, 455.
Kolk, Van der, On causes of insanity, 13; on brain, in insanity, 53.
Larmor, On congestion of brain, 425; on infantile paralysis, 668.
Laceration, of nerve, 720.
Laennec, On bronchial spasm, 769; On treatment of chorea, 136.
Lallemand, On softening of the brain, 449.
Lancereaux, On softening of the brain, 454.
Landouzy, On hysteria, 307, 316.
Laryngismus, in tetanus, 630.
Laryngismus stridulus, in chronic hydrocephalus, 400.
Lead, in brain, 501; induction of brain from, 484; poisoning by, diagnosis of, from writers' cramp, 258; palsy, distinction of, from wasting palsy, 173; tremors from, 204, 214 et seq.; diagnosis and treatment, 216.
Leaping ague, 118.
Leidenfrost, On general paralysis, 37.
Life, danger to, in epilepsy, 279; duration of, as affected by insanity, 54.
Lister, Mr. Joseph, On determination of blood, 45.
Literature, Of ulcer of stomach, 890.
Liver, cirrhosis of, in alcoholism, 74, 85.
Lividity, in epileptic attack, 266.
Local paralysis agitans, 195.
Local spasms, 765.
Lockhart, Mr. Clarke, On pathology of tetanus, 971.
Locomotor ataxy, diagnosis of, from muscular anaesthesia, 333.
Lordat, On aphasia, 443.
Louis, Dr. On meningial tumour, 410.
Lunatics, number of, in asylums, &c. 12, note.
Lung, gangrene of, in melancholia, 22; in alcoholism, 85.
Lucid intervals, in mania, 26; in melancholia, 22.
Lypemania, 19.
INDEX. 983

MacLachlan, Dr. on meningitis, 359, 369; on shaking palsy, 191.
Maclean, Dr. on sunstroke, 153.
McGregor, Dr. on tetanus, 635.
Malaria, relation of, to epid. cer. sp. meningitis, 699.
Malarial neuralgia, 721.
Malformations, of meninges, 411.
Malignant purple fever, 676.
Mammillation, in chronic gastritis, 880.
Martinet, M. on meningitis, 412.
Mania, 10.
Mania, acute, from drink, 79; chronic, 26; course of, 26; duration of, 26; description of, 22; diagnosis of, 40; forms of, 22; epileptic, 274; hysterical, 230; mode of death in, 26; potatorum, 63; preceding epilepsy, 15; prognosis in, 54; relation of, to melancholia, 22; sine delirio, 23; specific gravity of brain in, 51.
Marcet, Dr. on oxide of zinc, 87.
Mastication, in spinal meningitis, 600.
Masticatory spasm, 771.
Mart, on catalepsy, 104.
Marten, Thomas, on treatment of chorea, 132.
Masturbation, in mania, 24; relation of, to epilepsy, 287.
Maudsley, Dr. Henry, article on insanity by, 5.
Medulla oblongata, apoplexy of, 507.
Medullary cancer, of stomach, 936.
Meissner, on softening of brain, 455.
Melancholia, 10.
Melancholia, acute, 22; from drink, 79; atonita, resemblance of, to dementia, 20; description of, 18; diagnosis of, 41; forms of, 20; preceded by catalepsy, 104; prognosis, 54; relation of, to mania, 22, 23; relation of, to delusion; 18; varieties of, 19.
Melanoid cancer of stomach, 937.
Melanotic tumors, in brain, 490.
Membranes, in tubercular meningitis, 391; false, in meninges, 407.
Memory, changes of, in mania, 25; state of, in dementia, 30; in epilepsy, 269.
Membranes, of brain, changes of, in insanity, 49.
Ménière, on vertigo, 150.
Meningeal apoplexy, 405, 509.
Meningitis, simple, article on, including definition, acute meningitis, symptoms of, 356; inflammation of the dura matter, 363; progress, duration, pathological anatomy of, 364; etiology, diag-nosis, 366; treatment, 367; chronic meningitis, 389; diagnosis, 389.
Meningitis, tubercular, article on, see Tubercular Meningitis.
Meningitis, chronic, diagnosis of, from tumour of brain, 482; diagnosis of, from softening, 474; from epilepsy, 274, 278; in chorea, 126; from insanity, 39; from myelitis, 615.
Meningitis, epidemic cerebro-spinal, 676; relation of, to tubercular, 389.
Meningitis of spine, including symptoms, morbid anatomy, causes, 601; diagnosis, prognosis, treatment, 692.
Menstruation, in hysteria, 309; in epilepsy, 273; disturbances of, in relation to insanity, 15.
Mental condition, in epilepsy, 169; in alcoholism, 72; in hypochondriasis, 298; deficiency, in chorea, 312; depression, relation of, to alcoholism, 68; shock, a cause of epilepsy, 255 et seq.; state, in general paralysis, 38; in hysterio patients, 311.
Mercury palsy, or tremor, 205.
Mercury in insanity, 61.
Meryon, Dr. on wasting palsy, 167.
Mesmerism, relation of, to catalepsy, 105.
Metallic shaking, palsy, 205.
Metallic tremor, 205.
Meyer, on a cause of insanity, 17; on temperature in general paralysis, 38.
Micro-cephalie, 34.
Migraine, 724.
Miliary aneurism, 494.
Mind (see Mental condition), condition of, in apoplexy, 516; in locomotor ataxy, 845; in alcoholism, 66; in chronic softening of brain, 447; in congestion of brain, 414; in epilepsy, 270; in softening of brain, 436.
Mineral acids, in atomic dyspepsia, 820.
Moisture of atmosphere, relation of, to sunstroke, 158.
Monomania, 10, 23, 27; causes of, 28; duration of, 28; dangers of, 61; instinctive, 31; prognosis of, 55; relation of, to chronic mania and dementia, 26; repetition of words in dementia following, 20; raisonnable, 31.
Moral affections, perversion of, in insanity, 17.
Moral disturbance, cause of hysteria, 310; relation of, to insanity, 11.
Moral imbeciles, 32.
Moral insanity, 10, 23, 30; diagnosis of, 43.
Moral treatment of insanity, 57.
Moral, on causes of idiocy, 34.
Morbid anatomy, see Anatomy.
Morbid sleep, causes of, 109.
Moreau, M. on hereditary taint, in insanity, 13.
Morphia, hypodermic, injection of, 133, see Hypodermic injection.
Motility, condition of, in epileptics, 271; in softening of brain, 439; in meningitis, 358; in hysteria, 315.
Motor tract, implication of, in apoplexy, 507.
Movement cure, in chorea, 140.
INDEX.

Movements of the body, in ecstasy, 95.
Movement, relation of, to pain, in meningitis, 602; in myelitis, 608; to neuralgia, 729.
Movements, rhythmic, in chorea, 119; in metallic tremor, 208; in congestion of brain, 414.
Mouth, in tetanus, 632.
Murmurs, anaemic, in chorea, 123.
Mucous surface, anaesthesia of, 783.
Muscles, affected in infantile paralysis, 664; contraction of, in spinal irritation, 647; condition of, in wasting palsy, 173; primarily affected, in wasting palsy, 169; in tetanus, 628.
Muscular anæsthesia, article on, including definition, nomenclature, symptoms, 330; causes, diagnosis, 332; pathology, 333; prognosis, treatment, 334.
Muscular anæsthesia, local, 782.
Muscular development, in idiots, 35.
Muscular sense, in general paralysis, 37.
Muscular power, in chorea, 122.
Myalgia, diagnosis of, from neuralgia, 740.
Myelitis, including symptoms, 603; morbid anatomy, 613; causes, 614; diagnosis, 615; prognosis, 616; treatment, 616.
Myelitis, convulsive, 116.

NAHYTHA, in chorea, 138.
Narcotics, in paralysis agitans, 202.
Nausea, in spinal irritation, 645.
Nervs, diseases of, 705.
Nerves, division of, for neurona, 714; injury to, a cause of insanity, 17; roots of, in wasting palsy, 174; section of, in neuralgia, 752.
Nervous derangements, in dyspepsia, 800.
Nervous dyspepsia, 830.
Nervous diseases, classification of, 3; "general," 4; "partial," 5.
Nervous substance, condition of, in insanity, 45.
Nervous system, in chronic gastritis, 876.
Neuralgia, article on, including definition, synonyms, clinical history, and symptoms, 717; varieties, 719; traumatic, 725; intra-nervous, 721; malarial, 727; superficial and visceral, 723; migraine, 724; clavus hystericus, 725; cervico-occipital, 726; cervico-brachial, 727; dorso-intercostal, 729; dorso-lumbar, 731; crural and sciatic, 732; complications, 735; diagnosis, 739; prognosis, 741; pathology and etiology, 742; treatment, 744.
Neuralgia, diagnosis of, from hysteria, 324; relation of, to alcoholism, 69.
Neuritis, article on, 706; chronic, 707.
Neurona, article on, 706.
Neuroses of the stomach, including definition, etiology, 823; symptoms, 826; prognosis, 833; pathology, 834; diagnosis, 835; treatment, 837.
Niemeyer, on epilepsy, 252; on hysteria, 318.
Nosology, of epilepsy, 251.
Notional insanity, 27.
Notta, M. on neuralgia, 730, 735.
Numbness, in apoplexy, 514; in locomotor ataxy, 342; in neuralgia, 731.
Nutrition, degeneration of, in alcoholism, 85.
Nutrition, in epileptics, 272; in dyspepsia, 801; in chronic hydrocephalus, 400; in myelitis, 612; in dementia, 29.

OBSTRUCTION of the cardia, 251.
Odier, M. on neurona, 709.
Odour of breath, in alcoholism, 73.
Occupation, in relation to meningitis, 366; in the treatment of insanity, 58; relation of, to alcoholism, 67; to hysteria, 309; to wasting palsy, 166.
Oesophagus, spasm of, 770.
Oinomania, 79; prognosis of, 83.
Ollivier, on spinal disease, 598, 599, 608.
Optum, in chronic alcoholism, 88; in delirium tremens, 88, 91; in epid. cer. sp. meningitis, 702; in insanity, 69; in treatment of chorea, 137; poisoning by, diagnosis of, from apoplexy, 528; use of, inconvulsions, 249.
Optic thalamus, apoplexy in, 504.
Oscous tumour, in brain, 491.
Overwork, a cause of vertigo, 150.

PACHYMENINGITIS, in general paralysis, 50.
Packing, in insanity, 59.
Paget, Mr. James, on neurona, 710, 713.
Pain, in abscess of brain, 550; in cancer of stomach, 929; in cerebritis, 431; in chronic gastritis, 878; in head, in apoplexy, 522; in hypochondriasis, 297, 299; in hysteria, 313; in locomotor ataxy, 342; in myelitis, 608; in neurona, 710; in spinal congestion, 622; in spinal irritation, 644; in stomach, causes of, 787; on movement in meningitis, 597; in tetanus, 629; in ulcer of stomach, 907; significance of, 588.
Pallor, in catalepsy, 99; in epileptic attack, 265.
Pulsation, in dyspepsia, 801.
Palsy, shaking, 184.
Pantophobia, 19.
Paralysis, absence of, in spinal irritation, 648; absence of, in sunstroke, 161; absence of, in locomotor ataxy, 341; after convulsions, 225.
Paralysis agitans, article on, including definition, synonyms, 184; description, 187; causes, 195; diagnosis, 196; complications, pathology, and morbid anatomy, 198; treatment, 201; bibliography, 205.
INDEX.

Paralysis agitans, metallica, 205.
Paralysis, atrophic, 166.
Paralysis, general, of the insane, 36.
Paralysis, hysterical, 656.
Paralysis, in chronic softenings of brain, 448; in epilepsy, 275; in epid. cerebrospinal meningitis, 682; in hysteric, 316; in meningeal hemorrhage, 407; in spinal congestion, 621; in spinal meningitis, 598; in tumour of brain, 480; in tuberculous meningitis, 379.
Paralysis, local, 754; diagnosis of, from writers' cramp, 288.
Paralysis, spinal, physiology of, 580.
Paraplegia, diagnosis of, from locomotor ataxy, 351, 615; from muscular anæsthesia, 352; hysterical, 666; in myelitis, 607; in hysteric, 317; preceded by general muscular anæsthesia, 331.
Parchampe, on causes of insanity, 14; on general paralysis, 37.
Parkes, Dr. on sunstroke, 155.
Parkinson, on shaking palsy, 185.
Palpitation, in spinal irritation, 645.
Partial mania, 27.
Paroxysm, hysterical, 318.
Passions, depressing, as cause of insanity, 14.
Pathetic, or affective insanity, 32.
Pathological anatomy, see Anatomy.
Pathology, of abscess of brain, 551; of alcoholism, 84; of atonic dyspepsia, 810; of cancer of stomach, 934; of cerebritis, 431; of chronic gastritis, 879; of congestion of brain, 422; of epilepsy, 275; of gastric stricture, 952; of gastritis, 854; of hysteric, 320; of hypochondriasis, 303; of insanity, 44; of muscular anæsthesia, 333; of neuralgia, 742; of neuroses of stomach, 884; of paralysis agitans, 198; of writers' cramp, 259; of softening of the brain, 449; of sunstroke, 161; of wasting palsy, 175; of ulcer of stomach, 904.
Pearce, on dancing mania, 118.
Peysine, in atonic dyspepsia, 821.
Pereira, Dr. on action of phosphorus, 142.
Perforation, from cancer of stomach, 939; by gastric ulcer, diagnosis of, 918; of stomach, 904; from ulcer, 899.
Periodic mania, 26.
Periodicity, in somnambulism, 110.
Peritoniitis, from perforating ulcer of stomach, 902.
Petit mal, description of, 260.
Phantom tumour, in hypochondriasis, 300; diagnosis of, 324.
Pharynx, spasm of, 770.
Phillipeaux, on softening of brain, 465.
Phlebidus, 261.
Phosphorus, in chorea, 141; in chronic alcoholism, 88.
Phosphates, in urine, of acute mania, 25.
Phthisis, relation of, to alcoholism, 84.
Physical exercise, in hypochondriasis, 305.
Pica, 827.
Pigmentation, in chronic gastritis, 879.
Pinéal body, alterations of, 492.
Pituitary body, alterations in, 492.
Plaques jaunes, 468.
Plthora spinalis, 619.
Pneumonia, in delirium tremens, 82, 84; treatment of, 93.
Pons Varoli, apoplexy of, 507.
Portio dura, paralysis of, 757.
Position, in chorea, 139.
Potassium, bromide of, in chorea, 137; in epilepsy, 280, 906.
Potassium, iodide of, in chorea, 137.
Poverty, relation of, to drunkenness, 68.
Pregnancy, a cause of chorea, 125; insanity during, 16.
Prevention of disease in metal workers, 212.
Prevost et Cotard, on softening of brain, 453 et seq.
Priapism, in spinal meningitis, 600.
Prichard, Dr. on moral insanity, 30.
Prognosis, of apoplexy, 536; of atonic dyspepsia, 813; of cancer of stomach, 934; of cerebritis, 433; of alcoholism, 81; in delirium tremens, 82; of congestion of brain, 427; of convulsions, 236; of epid. cerebrospinal meningitis, 690; of epilepsy, 279; of stomachal vertigo, 146; in facial palsy, 761; of gastric ulcer, 915; of hematemesis, generally, 948; in hysteric, 324; in hysterical paralysis, 657; in insanity, 54; of lead tremor, 215; in locomotor ataxy, 354; of muscular anæsthesia, 334; of myelitis, 616; of metallic tremor, 211; of neuralgia, 741; in neuroses of stomach, 883; of paralysis agitans, 200; of pyloric obstruction, 956; of hypochondriasis, 301; of spinal congestion, 124; of spinal irritation, 652; of spinal meningitis, 602; of softening of brain, 475; of sunstroke, 162; of tetanus, 637; of tuberculous meningitis, 396; of tumour of brain, 502; of vertigo, 145; of wasting palsy, 181; of writers' cramp, 289.
Prophylactic treatment, see Treatment.
Prophylaxis, of sunstroke, 163.
Progressive muscular atrophy, 166.
Prussic acid, symptoms of poisoning by, resembling apoplexy, 521.
Ptosis, in locomotor ataxy, 343.
Puerperal convulsions, relation of, to epilepsy, 257.
Pulse, in apoplexy, 517; depression of, in rotatory movement, 121; in epileptic attack, 266; in epid. cerebrospinal meningitis, 685; in mania, 25; state of, in delirium tremens, 77.
INDEX.

Pupils, in apoplexy, 518; in epileptic attack, 266; inequality in the size of, in general paralysis, 37; in local palsy, 764; in locomotor ataxy, 345; in spinal poisoning, and in apoplexy, 528; in softening of brain, 493; in sunstroke, 161; in tetanus, 632; state of, in catalepsy, 100.

Purgation, in insanity, 60; in delirium tremens, 89.

Purpuric epid. cer. sp. meningitis, 650.

Pyemia, relation of, to abscess of brain, 547.

Pylorus, obstruction of, 953.

Pyrosis, 798.

Quarantine, in treatment of epidemic convulsive affections, 98.

Quarantine fever, relation of, to catalepsy, 104.

Quicksilver workers, 205, 210.

Radcliffe, Dr. C. B. on locomotor ataxy, 336; on chorea, 114; on diseases of the spinal cord, 380.

Radcliffe, Mr. J. Netten, on epidemic cerebro-spinal meningitis, 676.

Rayer, M. on neurama, 714.

Ramskill, Dr. J. Spence, on vertigo, 144; on chronic hydrocephalus, 397; on meningal hemorrhage, 465; on adventitious products in the meninges, 499; on malformations of the meninges, 411; on simple meningitis, 356.

Ramollissement, acute, 432.

Ramollissement of brain, see Softening.

Raptus melancholicus, 21.

Raving madness, 24.

Recurrent mania, 26.

Red softening of brain, 462.

Reflex action, in insanity, 47.

Reflex excitability, in spinal meningitis, 600.

Reflex movements, in hysteria, 316; in myelitis, 609; in spinal congestion, 621; in tetanus, 630.

Reflex paralysis agitans, 194.

Reflex paraplegia, 657.

Regimen, in atonic dyspepsia, 816.

Respiration, forced, physiology of, 587; in catalepsy, 99; in epid. cer. sp. meningitis, 655; in epileptic attack, 265, 266; in tubercular meningitis, 377; irregularity of, in chorea, 121; in metallic tremor, 260.

Restlessness, an early symptom of alcoholism, 71; in myelitis, 607.

Restraint, in delirium tremens, 93; in insanity, 57.

Retina, in convulsions, 244.

Reynolds, Dr. J. Russell, on epilepsy, 251; on congestion of the brain, 413; introduction to diseases of the nervous system, 3; on adventitious products in the brain, 478; on cerebritis, 430; on hysteria, 366; on muscular anesthesia, 330; on paralysis agitans, 200, 202; on softening of the brain, 494; on symptoms of meningeal hemorrhage, 465; on torticollis, 774; on writers cramp, 283.

Rheumatic meningitis, 360.

Rheumatism, acute, apoplectic attack in, 438; a cause of insanity, 16; in chorea, 123.

Rheumatism, relation of, to neuritis, 708.

Rheumatismus metallicus, 205.

Rhythmic sounds, effect of, in chorea, 119.

Rhythmic movements, in chorea, 119.

Ricketts, diagnosis of, from hydrocephalus, 402.

Rigidity, in tubercular meningitis, 379; late, in softening of brain, 444.

Rigor mortis, in tetanus, 633; with pain, in meningitis of spine, 598.

Ritis sardonicus, in tetanus, 629.

Killie, on meningitis, 365; on tubercular meningitis, 375, 384, 389.

Robin, on congestion of brain, 422; on softening of brain, 467.

Roberts, Dr. Wm. on convulsions, 248; on wasting palsy, 166.

Roger, Henri, on treatment of chorea, 136.

Romberg, on chorea, 123; on locomotor ataxy, 336; on treatment of chorea, 132.

Rostan, on softening of the brain, 449.

Rotatory movement, in chorea, 120, 121; pathology of, 126.

Rokitansky, on neurama, 714; on tumour in spinal cord, 699; on diseases of stomach, see articles on Stomach.

Round ulcer, of stomach, 889.

Rupture of stomach, 964.

Rush, Dr. on tetanus, 635.

Rhythmic movements, in treatment of convulsive diseases, 98.

Sagar, on ecstasy, 95.

St. Augustine, on catalepsy, 104.

St. Guy, dance of, 114.

St. John, dance of, 116.

St. Vitus, dance of, 96, 114; relation of, to shaking palsy, 185.

Salter, Dr. Hyde, on spasmodic asthma, 767.

Sandaret, Dr. on mercurial disease, 410.

Sanderson, Dr. Burdon, on epid. cer. sp. meningitis, 681 et seq.

Sanders, Dr. W. Rutherford, on paralysis agitans, 184; on facial palsy, 759.

Sarcina ventriculi, 793.

Sardonic spasm, 771.

Saunders, Dr. on temperature in mania, 25; on temperature in general paralysis, 39.

Sauvages, on catalepsy, 104; on shaking palsy, 190.

Schiff, on division of nerves, 180.

Sciatica, 732.

Sciatic neuritis, 708.
INDEX.

987

Scirrhous of stomach, pathology of, 935.
Sclerosis of brain, in idiocy, 34; in insanity, 51; of spinal cord, 693; of stomach, 949.
Scriveners' palsy, 285; see Writers' Cramp.
Scrofula, in relation to chronic gastritis, 877.
Section, changes of, in stomach disease, 799.
Secretions of stomach, excessive, 796; penetrated, 797; arrested, 798.
Séé, M. on chorea, 140.
Self-abuse, a cause of insanity, 15; of moral insanity, 32; see Masturbation.
Sensation, in chorea, 123.
Sensation, in hysteria, 312; in infantile paralysis, 662; loss of, in alcoholism, 75; in spinal congestion, 621; in tumour of brain, 479.
Sensation movements, in hysteria, 316.
Senses, condition of, in idiocy, 35; in congestion of the brain, 414.
Senses, special, in epid. cerebrospinal meningitis, 682.
Senses, perverted, in, vertigo, 144.
Sensibility, affections of, in melancholia, 19; in softening of brain, 438; in general paralysis, 37; in spinal meningitis, 599; in wasting palsy, 172.
Sensory anesthesia, 783.
Sensorial changes, in epilepsy, 263, 271.
Seros apoplexy, 529.
Sequela, of convulsions, 225; of epileptic attack, 267; of sunstroke, treatment of, 165.
Sex, as predisposing cause of insanity, 12; effect of, on prognosis in insanity, 56; in relation to epilepsy, 254; to hysteria, 307; to neurona, 710; to cancer of stomach, 926; to locomotor ataxy, 350; to meningitis, 966; to chorea, 124; to hypochondriasis, 302; to wasting palsy, 166.
Sexual condition in hysteria, 308.
Sexual functions, relations of, to dementia, 28.
Sexual power, in locomotor ataxy, 334.
Shaking palsy, 184.
Shaw, Mr. on malformation of membranes, 411.
Sheath, lymphatic, of cerebral vessels, 422.
Shock, a cause of dementia, 28.
Shock, mental or moral, as a cause of insanity, 11; see Epilepsy, Hysteria.
Shower bath, in insanity, 69.
Sick headache, 724.
Siderant, or fulminating, epid. cerebrospinal meningitis, 679.
Sign, in locomotor ataxy, 343; in meningitis, 358.
Simon, Mr. J. on epid. cerebrospinal meningitis, 691.
Sinuses, cranial, obstruction of, 456.
Singultus, 770.
Skin, in chronic gastritis, 873; in dyspepsia, 800; in epid. cerebrospinal meningitis, 682; in mania, 25; in metallic tremor, 209.
Skull, irregularities of, in idiocy, 34.
Sleep, absence of, in tetanus, 631; in delirium tremens, 73; prognostic value of, in delirium tremens, 82.
Sleep-walking, article on, 109.
Sleeplessness, an early symptom of alcoholism, 71; in insanity, 49.
Smith, Mr. Robert, on nevroma, 708, 710.
Softening, non-inflammatory, of spinal cord, 667.
Softening of the brain, article on, including definition, causes, 434; symptoms, 435; acute softening, 6b; forms of, 436; aphasia in, 441; chronic softening, 447; pathology, 449; embolism in, 453; diagnosis, 471; prognosis, 475; morbid anatomy, 460; white softening, 461; red softening, 462; yellow softening, 464; treatment, 476; diagnosis of, from congestion, 420; chronic, diagnosis of, from tumour, 492; red, of brain, 432.
Softening of the stomach, 958.
Solly, Mr. on writers' cramp, 292.
Somnambulism, article on, 109; dangers of, 110; treatment of, 112.
Spasmodic epidemics, 96.
Spasm, choreic, in epileptic attack, 266; general significance of, 592.
Spasm, in chronic softening of brain, 448; in cholera, 773; in epid. cerebrospinal meningitis, 681; in le petit mal, 261; in myelitis, 608; relation of, to fever, in hooping cough, 130; tonic and clonic, in epilepsy, 265 et seq.
Spasms, local, 765.
Specific gravity, of brain, in insanity, 51; in softening, 12.
Speech, absence of, in tubercular meningitis, 385; in apoplexy, 506, 514; in metallic tremor, 211; in softening of brain, 440; in wasting palsy, 171.
Spermatorrhea, in somnambulism, 113.
Sphincters, in myelitis, 610; in spinal congestion, 621; in spinal meningitis, 599; in tetanus, 632.
Sphygmograph, indications of, in delirium tremens, 77; prognostic value of, in delirium tremens, 82; representation of effects of alcohol by, 65.
Spina bifida, 674.
Spinal cord, condition of, in chorea, 127.
Spinal cord, diseases of, articles on, 680; including preliminary remarks, 6b; meningitis, 694; myelitis, 608; congestion, 619; tetanus, 624; irritation, 640; general spinal paralysis, 653; hysterical paralysis, 656; reflex paralysis, 657; infantile paralysis, 661; haemorrhage, 666; non-inflammatory
INDEX.

softening, 667; induration, 668; atrophy and hypertrophy, 669; tumour, 699; concussion, 671; depression, 672; caries of vertebrae, 672; spina bifida, 674; epidemic cerebro-spinal meningitis, 676.

Spinal cord and nerves, condition of, in wasting palsy, 174, 179.

Spinal irritation, symptoms of, 640; relation of, to regions, 646; anatomy, causes, diagnosis of, 650; prognosis, treatment of, 652.

Spinal paralysis, general, 653.

Spirits, abuse of, in chronic gastritis, 869. "Spleen, the," 293.

Spotted fever, 677.

Stammering, relation of, to chorea, 122.

Starvation, a cause of gastritis, 842; relation of, to alcoholism, 68.

Stenosis of the carida, 951; of pylorus, 963.

Suicidal impulse, in melancholia, 21.

Suicide, tendency to, in alcoholism, 75.

Sugar, production of, in alcoholism, 85.

Sutherland, Dr. on urine of mania, 25.

Sutton, Dr. on abscess of brain, 544.

Sunstroke, a cause of insanity, 16.

Sunstroke, article on, including definition, synonyms, history, 153; etiology, 157; symptoms, 159; diagnosis, pathology, 161; morbid anatomy, mortality, 162; prophylaxis, treatment, 163; treatment of sequelae, 165.

Stimulants, see Treatment.

Stomach, condition of, in alcoholism, 84; diseases of, 785; functional disorders of, 786 of seq.

Stomatich vertigo, 146.

Stapor, of epilepsy, 267.

Strabismus, 772; in locomotor ataxy, 343.

Strength of epileptics, 272.

Stricture of carida, 951.

Strychnia, in chorea, 135; in chronic alcoholism, 88; in myelitis, 617; poisoning by, diagnosis of, from tetanus, 637.

Swallowing, in tetanus, 629.

Sydenham, description of chorea by, 114.

Sympathetic nerves, in wasting palsy, 180.

Sympathetic system, in hysteria, 331.

Sympathy, in insanity, 47.

Symptoms, of metallic tremor, 207; of tubercular meningitis, 376; of abscess of brain, 549; of acute alcoholism, 76; of acute meningitis, 556; of alcoholism, 71; of chronic alcoholism, 71; of atomic dyspepsia, 807; of cancer of stomach, 927; of cerebritis, 430; of chronic gastritis, 870; of congestion of the brain, 414; of convulsion, 231; of epidemic cerebro-spinal meningitis, 677, 689; of epilepsy, 259; of gastritis, 846; of hypochondriasis, 296; of hysteria, 311; of insanity, 17; of menin-geal hemorrhage, 466; of muscular anesthesia, 330; of myelitis, 603; of obstruction of pylorus, 953; of perforation of stomach, 913; of shaking palsy, 157; of spinal congestion, 619; of spinal irritation, 640; of softening of the brain, 435; of stomach neuroses, 826; of sunstroke, 159; of tetanus, 625; of torticollis, 775; of ulcer of stomach, 907; of wasting palsy, 169; of writers' cramp, 285.

Syncope, diagnosis of, from epilepsy, 276; from congestive apoplexy, 421.

Synergy, of eye-balls, in softening of brain, 439.

Syphilis, a cause of dementia, 15; in relation to chronic gastritis, 870; of meningitis, diagnosis of, 484.

Syphilitic disease, of brain, prognosis in, 502; growth, in brain, anatomy of, 458; insanity, anatomy of, 51; meningitis, 302.

Syphiloma, in insanity, 51.

Tapes dorsalis, 336.

Tapping, in hydrocephalus, 403.

Tarantism, 97, 117.

Tartar emetic, in chorea, 136.

Teale, Mr. T. P. on spinal irritation, 640.

Temperature, a guide in the prognosis of insanity, 54; in epileptics, 272; in epip. cer. sp. meningitis, 687; in mania, 25; of head, in general paralysis, 38; of the body, 39; local, in meningitis, 714; in tubercular meningitis, 478; in tetanus, 630.

Temperament, in hysteria, 308; in spinal irritation, 649; in relation to meningitis, 905; in relation to insanity, 13.

Tenderness of spine, in meningitis, 599; in spinal irritation, 643; in myelitis, 610.

Teuder spots, in neuralgia, 715.

Tetanoid spasms, in epid. cer. sp. meningitis, 678.

Tetanus, relation of spasms to pulse, 129.

Tetanus, 624; including symptoms, 625; anatomy, 634; causes, 635; diagnosis, 636; prognosis, 637; treatment, 638; diagnosis of, from epid. cer. sp. meningitis, 689.

Thickening, in chronic gastritis, 880.

Third nerve, paralysis of, 763.

Thrombosis, in sinususes, diagnosis of, 390; in softening of brain, 453.

Thunder, effect of, on cataleptics, 100.

Thurran, Dr. on insanity, 12; prognosis of insanity, 56.

Tic epilepticiform, 726.

Tigrétié, 118.

Tigges, on brain in insanity, 52.

Tinnitus aurium, in alcoholism, 72; in vertigo, 144.

Tissot, on catalepsy, 102.
INDEX.

Todd, Dr. on local paralysis, 754; on hysterical paralysis, 316; on late rigidity, 444; on locomotor ataxy, 336; on myelitis, 614; on urine in chorea, 124.

Tongue, in cancer of stomach, 932; in chronic gastritis, 872; in delirium tremens, 78; in ulcer of stomach, 912.

Tonic spasm, in hysteria, 316; in shaking palsy, 189.

Topinard, on muscular anæsthesia, 333.

Torticollis, article on, 774.

Torticollis, spasmodic, injections of arsenic in treatment of, 134.

Toxic, paralysis agitans, 194.

Toynbee, on absence of brain, 546.

Trachealismus, 361.

Tracheotomy, in epilepsy, 284.

Trance, in catalepsy, 163.

Traumatic haemorrhage, 527.

Traumatic neurœma, 714.

Treatment, of absence of brain, 556; of alcoholism, 88; of apoplexy, 541; of atonic dyspepsia, 814; of catalepsy, 108; of cancer of stomach, 944; of cerebritis, 433; of chorea, 131; of chronic alcoholism, 86; of chronic gastritis, 884; of chronic meningitis, 370; of congestion of brain, 428; of convulsions, 257; of estacy, 97; of epid. cereb. meningitis, 701; of epilepsy, 250; of gastritis, 561; of gastric stricture, 952; of gastric ulcer, 919; of hematemesis, generally, 949; of hypochondriasis, 393; of hydrocephalus, 402; of hysteria, 325; of lead tremor, 216; of locomotor ataxy, 352; of local spasms, 773; of metallic tremor, 212; of meningeal haemorrhage, 408; of meningitis, 367; of muscular anæsthesia, 325; of myelitis, 616; of neuralgia, 744; of neuroses of stomach, 837; of paralysis agitans, 201; of pyloric obstruction, 957; of reflex paraplegia, 660; of spinal irritation, 652; of softening of brain, 476; of spinal meningitis, 602; of spinal congestion, 624; of somnambulism, 112; of sunstroke, 163; of tetanus, 638; of torticollis, 779; of tumour of brain, 503; of tubercular meningitis, 396; of vertigo, 151; of writers' cramp, 292.

Tremblement du métal, article on, 205, including synonyms, definition, and causes, 205; symptoms, 207; course, prognosis, and diagnosis, 211; pathology, 212.

Tremblement des doreurs, 235.

"Trembles, the," 205.

Tremor artæum, 184.

Tremor, in chronic alcoholism, 71; in delirium tremens, 78; in epileptics, 271; in locomotor ataxy, 345; mettallurgorum, 205; in wasting palsy, 172; saturninus, 215.

Trigeminal neuralgia, 723.

Trismus nascentium, 613.

Trousseau, on aphasia, 441; on chronic hydrocephalus, 399, 401, 403; on hydrocephalic cry, 379; on meningæal rheumatism, 361; on muscular anæsthesia, 333; on somnambulism, 112; on treatment of chorea, 135.

Tuberele, in brain, prognosis of, 502; anatomy of, 486; in meningoes, 392; in relation to chronic gastritis, 868.

Tubercular meningitis, article on, including causes, 371; symptoms, 372; primary tubercular meningitis in the child, 388; tubercular meningitis in the adult, 385; diagnosis, 386; morbid anatomy, 391; prognosis and treatment, 392; in the adult, 385.

Tuberele, on brain, diagnosis of, 483; on spinal cord, 669; of stomach, 961; painful sub-cutaneous, 709.

Tuberele, sub-cutaneous, 709.

Tuberculosis, association of, with mental disease, 15; with ulcer of stomach, 894.

Tuke, Dr. Hack, on classification of idiots, 35.

Tumour, of brain, diagnosis of, from tubercular meningitis, 391; in cancer of stomach, 931; of brain, diagnosis of, from absence, 555; from epilepsy, 278; from softening, 474; see Adventitious Products.

Tumour, of nerve (see Neuröma), 703; of spinal cord, 669.

Turkish bath, in insanity, 59.

Turpentine in chorea, 138.

Türck, on nerves after amputation, 180.

Typhoid, diagnosis of, from tubercular meningitis, 388; from meningitis, 367.

Ulcer, chronic, of stomach and duodenum, including synonyms, definition, 889; history, 890; etiology, 891; morbid anatomy, 895; pathology, 904; symptoms, 967; prognosis, course, and duration, 915; diagnosis, 917; treatment, 918.

Ulcer of stomach, diagnosis of, from cancer, 942; from chronic gastritis, 884; perforating, of stomach, 889.

Ulceration, in cancer of stomach, 938.

Ulnar neuralgia, 728.

Urethra, spasm of, 770.

Uremia, in serous apoplexy, 529; diagnosis of, from congestion of brain, 420; from softening of brain, 473.

Urinary condition, in sunstroke, 158; in paraplegia, 658; in dyspepsia, 800; in myelitis, 611; in chronic gastritis, 875; in mania, 25; in tubercular meningitis, 381; in epilepsy, 267; in chorea, 124.
INDEX.

Uterus, displacement of, of a cause of insanity, 16.
Uvula, in facial palsy, 759.

VALLIX, on neuralgia, 717.
Van Swieten, on catalepsy, 103.
"Vapours, the," 293.
Veius, in epilepsy, 267; obstruction of, in brain, 456.
Veitricular hydrocephalus, 398.
Ventricles, lateral, hemorrhage into, 508; condition of, in tubercular meningitis, 383.
Vertebrae, caries of, 673.
Vertigo, article on, including definition and description, 144; from overwork, 150; in epid. cer. sp. meningitis, 683; in epilepsy, 260; of the aged, 146.
Vessels, in cerebral congestion, 425; rigidity of, relation to softening of the brain, 445.
Vibration, muscular, in wasting palsy, 172.
Vigia, on meningeal rheumatism, 361.
Visceral neuralgia, 735.
Vomiting, in alcoholism, 73; in apoplexy, 522; in cancer of stomach, 929; in chronic gastritis, 877; in epid. cer. sp. meningitis, 684; in meningitis, 357; in neuroses of stomach, 530; in stomach disease, 790; distinction of, from cerebral, 791; in tubercular meningitis, 374; in ulcer of stomach, 910.
Vulpian, on softening of brain, 465.

WALSH, Dr. on cancer in brain, 489; on cancer of stomach, 925; on urine in chorea, 124.
Warburg's tincture, a sudorifice, 164.
Ware, Dr. on delirium tremens, 64.
Wasting, in wasting palsy, 170.
Wasting palsy, article on, including definition, synonyms, history, etiology, 166; symptoms, 169; course and duration, 172; diagnosis, 173; anatomy, 178; pathology, 178; prognosis, 181; therapeutics, 182; diagnosis of, from writers' cramp, 283.
Watson, Sir T. on age in chorea, 124; on chronic hydrocephalus, 397, 401; on meningeal rheumatism, 362; on the treatment of chorea, 131, 132.
Weber, Dr. Hermann, on temperature in mania, 25.
Well, on insanity, 52.
West, Dr. on chronic hydrocephalus, 397, 399; on convulsions, 221, on infantile paralysis, 662.
White softening of brain, 461.
Whytt, Dr. Robert, on tubercular meningitis, 375.
Wood, Dr. Kinder, on chorea, 119.
Wood, Mr. William, on neuroma, 709, 710, 715; on sub-cutaneous tubercle, 709.
Woodman, Dr. on a case of apoplexy, 525.
Worms, as a cause of catalepsy, 108.
Wilks, Dr. on apoplexy, 529; on atrophy of brain, 50; on convulsions, 228; on uou-inflammatory softening of cord, 667; on pupils in apoplexy, 518; on syphilitic growths in brain, 488; on ventricles of brain, 496.
Will, relation of, to complicated movements, 290.
Willis, Dr. on spasmodic diathesis, 13; on hypochondriasis, 294.
Williams, Dr. Duckworth, on treatment of epilepsy, 258.
Wisdom teeth, cutting of, in epilepsy, 257.
Writing, in softening of brain, 241.
Writers' cramp, article on, including definition, symptoms, synonyms, 285; etiology, diagnosis, 288; prognosis, pathology, 289; treatment, 292.
Wry-neck, article on, 774 (see Torticollis).

YELLOW softening of brain, 464.

ZINC, in treatment of epilepsy, 280; of chorea, 132; of chronic alcoholism, 87.
